13,917. (*Mr. Lumley Smith.*) And what is your furthest point to which you go?—Blackwall Point. There is one other diagram to which I wish to call your attention, and which is very important.

13,918. (*Sir John Coode.*) Are you sure that you have got the same standard of low water that you had in the year 1796?—Yes. I was very careful about that. I had the wharves in a sufficient number of places where they had not been altered, to give me bench marks at frequent intervals.

13,919. And the levels of the earliest date you have ascertained?—They were shown. The wharf wall was upon one section, and I was able by comparing the wharf walls upon different sections to ascertain their identity.

13,920. (*Mr. Abernethy.*) I suppose those sections show that if you enlarge the sectional area in any part of the river, shoals rise up?—No, these are to show that from natural causes the Thames was scouring above London Bridge and depositing below London Bridge.

13,921. But the removal of London Bridge was not a natural cause; that was a physical operation?—But after that physical operation, the banks above London Bridge were scoured out and deposited in the Pool owing to the insufficiency of the current to carry the solid matter further onwards. Now this *Diagram No.* 18 (*see Appendix BL.*) shows that the level of the marshes inside the sea wall, as it is termed, or bank, and which has been made for the protection of those marshes, is on this particular section, 5 feet lower than the level of the saltings outside; and that therefore shows with absolute certainty that since the sea wall was built the river has deposited sufficiently to raise its surface by 5 feet, that the deposit which has been going on for a very long period, imperceptibly almost, has gradually raised the level of those thousands of acres outside the sea wall to a height of 5 feet, and that was confirmed by what was found in sinking the shaft for the Thames Tunnel upon the Wapping side, where we cut in half a line of old wharf, about 70 feet within the then existing line, and with the top of it 5 feet lower than the then level of the surface of the ground. In fact, we have proof all the way down the river that the river, as many, and, indeed, almost all rivers do, has been raising its bed. Now I have here (*shewing some charts*) two Admiralty charts of the same part, namely, the mouth of the river, as published in 1856 and as published at the present time, and I have prepared four sections at points upon the plan which will be laid before the Commission. (*Diagram No.* 35; *see Appendix AZ.*)

13,922. (*Chairman.*) Your object now, as I understand, is to show that deposits have taken place and elevations of parts of the bed of the river?—My object is, and I have now just finished this part of my examination, to show you the extent to which these changes take place—the enormous magnitude of the deposits which are taking place—and that therefore anything which might come from the sewers would in no way affect it generally, and then I am going to show you the local cause of the banks which exist in the immediate neighbourhood of the outfall.

13,923. I cannot help thinking that the latter part is the relevant matter?—I have just finished this part of the case. This is the last fact that I am bringing before your notice, and the effect of it is to show that at the mouth of the river itself considerable silting is taking place. By a comparison of the shore lines, you will find that while the high water line is being washed away, the low water line is being extended out into the river to the extent of 1,000 yards at the mouth of the Thames.

(*Sir John Coode.*) The term "mouth of the Thames" is a little vague—would you kindly tell us the particular part of the section you are referring to.

(*Chairman to Mr. Lumley Smith.*) You will not dispute, I presume, that there have been raisings of part of the bed of the river.

(*Mr. Lumley Smith.*) I believe that is the fact, no doubt.

(*Witness.*) Within the last week only, three acres of a cliff, 70 feet in height, in the Isle of Sheppey, have been washed away, carrying away a churchyard into the river.

13,924. (*Mr. Abernethy.*) That was a land slip?—Yes, carrying the land of a churchyard into the river, the church having been previously removed. Then I would wish now to point out that many of the changes, and the very banks that are now spoken of, have arisen to a great extent from artificial dredging carried on at those points, that up to the year 1858 when the Conservators were appointed, the only dredging which took place in the river Thames was that upon the part of the Trinity Corporation, who simply dredged for gravel where it was suitable for ballast, for the purpose of selling it.

13,925. (*Sir John Coode.*) And for no other purpose?—For no other purpose; and it was not until the Conservators were appointed under Act of Parliament, that they provided themselves with extremely powerful dredging machines, and resorted to the use of gunpowder to break up iron bound gravels which had existed in the bed of the river, forming shoals, or "shelves," as they were called, such as Barking Shelf, Ham Shelf, and Erith Shelf. Those various shoals or shelves extended out principally from the northern side, and drove the current over to the southern side. A very great improvement was effected, as far as the navigation was concerned, by the removal of those shoals; but the result was to enlarge the section of the river to such an extent that the velocity became diminished, and a deposit took place in those parts of the river where the current having been diverted over to where the channel had been dredged the other side of the channel was left in an eddy and in still water. I am now going to show the commencement of the formation of the shoals in the neighbourhood of the outfalls previously to the outfalls being put there, which I think is a very important point. The plan which will be now laid before your Lordship will

show the position of certain sections which I took (*Diagram No. 6 handed in; see Appendix B.A.*) This is the plan of the river from just below Woolwich to near Erith, and it comprises Barking Reach and Halfway Reach, in which the two sewage outfalls are situated. The northern outfall your Lordship will see at the right hand corner, and the southern outfall about nearly over the word "Kent" on the southern side. The dotted lines across show the lines of sections which will now be handed to your Lordship, and those sections show a comparison of the soundings taken in 1833 by Captain Bullock and Captain Burstall jointly, with those taken in 1861 by the Conservators and in 1864 by the Surveyor to the Board of Works, Mr. McDougal; and beneath you have the section of 1861 compared with that of 1864. (*Diagrams Nos. 7 to 13 were handed in; see Appendices BB. 1 to 7.*) There is a series of sections given upon the several lines, and from those you will see that owing to the removal of the shoals, as shown by the red colour, the accumulations commenced as shown by the brown; and I will put in a table which gives the sectional area of the river on these several lines in 1861, and the mean velocity of the stream at half ebb, as compared with the sectional area and velocity in 1864, if there had been no deposit, and as compared with that which was actually the case in 1864 after the deposit had taken place. I will take one case as an illustration—taking the line A A., the sectional area at half ebb in 1861 was 42,990 square feet, and the mean velocity through that section was 176 feet, that was sufficient to keep it clean. By the dredging which took place in 1864, if no deposit had taken place, there would have been a sectional area of 46,670 as against 42,990. The velocity being reduced to 162 instead of 176, it could no longer keep itself clean, and it deposited mud upon the southern side where the stream was not so strong, and reduced itself to a sectional area of 45,710 increasing the velocity to 165, which, although 11 feet less than it had previously been, was of course quicker than it would have been if no deposit had taken place, and as this dredging has gone on so has the deposit gone on. But the simple object of these sections is to show you that the dredging having commenced previously to the construction of the outfalls, so the deposit also had commenced upon the lines of these very banks. A careful examination of these sections will show that where dredging was, deposit take place, and that the deposit was the nucleus or commencement of the banks of which complaint is now made.

*Table 9 was handed in, and is as follows:*

TABLE 9.

COMPARISON of the VELOCITIES of the EBB STREAM at HALF EBB of an AVERAGE TIDE in 1861 and in 1864, in feet per minute.

| Locality; reference to Drawing L and C, No. 6. | Actual in 1861. | | In 1864, if there had been no Deposit. | | Actual in 1864. | |
|---|---|---|---|---|---|---|
| | Sectional area in square feet. | Mean Velocity. | Sectional area in square feet. | Mean Velocity. | Sectional area in square feet. | Mean Velocity. |
| Line A.A. - | 42,990 | 176 | 46,670 | 162 | 45,710 | 165 |
| „ B.B. - | 50,812 | 159 | 55,850 | 144 | 52,895 | 152 |
| „ C.C. | 51,030 | 170 | 56,670 | 153 | 54,200 | 160 |
| „ D.D. - | 54,670 | 163 | 57,610 | 154 | 49,560 | 179 |
| „ E.E. - | 54,185 | 158 | 58,060 | 154 | 53,700 | 167 |
| „ F.F. - | 47,780 | 191 | 54,190 | 168 | 52,600 | 173 |

13,926. (*Chairman.*) Your theory is, area of river increased, velocity of water therefore diminished, and, consequently, greater capacity for deposit?—Yes, and something more than that; that the diversion of the current owing to the form of the river upon the plan left certain parts in slack water, and caused a deposit to take place in these places. Plan No. 5 (*handing in the same; see Appendix BC.*) is a plan of the river from Jenningtree Point to Crayfordness, comprising the two parts of the river called Erith Reach and Erith Rands, and the brown spots upon the plan are spots where mud was shown to exist by the Conservators upon their plan made in 1861, and therefore it will show upon their own evidence what was the state of the river as regards the muddy bottom at that date.

13,927. (*Mr. Abernethy.*) That comes back to the other proposition of a short time ago, that if by dredging or other operations you alter the direction and the velocity of the mean current, shoals will form in other parts of the river?—Yes, but the object of this plan is to show that mud existed in the very parts of the river in 1861 where mud is found to-day.

(*Mr. Abernethy.*) There is no doubt about it.

(*Witness.*) I now put in four plans of the same part of the river, Nos. 1 to 4, coloured so as to show the depth of water. (*The same were handed in; see Appendices BD. 1 to 4.*) Plans 1 to 4 are plans showing the form and depth of channel in 1831 from the soundings of Captain Bullock; in 1861 from the soundings of the Conservators; in 1879 from the soundings of the Conservators; and in 1882 from soundings taken by ourselves. In order to show graphically the change in the river and the depth, the colour is proportional to the depth of water. If, therefore, your Lordship will compare plan No. 1 with plan No. 2, you will see that between those two years the shoal which extended out from Great Cold Harbour Point, which is called Erith Shelf, had been nearly removed. In 1833, when that shelf existed, and also Erith Rands, which is the white patch below Erith in the middle of the river, the current was diverted upon the southern side; and near where you see a dark patch just opposite Rainham, vessels used to lie, and higher up there was a berth for colliers going up the river. Subsequently, if you compare 1833 with 1882, you will see that the deep channel now is upon the northern side. I shall show you from actual observation that the run of the tide is upon the northern side, and that the south side, where the deposit is now taking place, is left in slack water. I have one small table which I would put in, being merely a resumé of the contents of the small plan No. 20; *see Appendix BE.*) (to which I need hardly refer you) upon a small scale of this part of the river. The river has been divided into 8 sections, and the cubic contents of those sections has been calculated, and it shows that the increase in the cubic content of the water since 1833 has averaged about 23 per cent., and that the increase since 1861 has been nearly 3 per cent., and that the increase since 1879 has been nearly 2 per cent., and that increase is still going on, notwithstanding that deposit.

*Table 10 was handed in, and was as follows:*

TABLE 10.

TABULAR STATEMENT showing the Low-water Capacity of Divisions 2, 3, and 4 of the River Thames, derived from the Soundings of 1833, 1861, 1879, and 1882.

| Date. | Total of Divisions 2, 3, and 4. | | | Percentage of Increase of Total Contents of Channel. | | |
|---|---|---|---|---|---|---|
| | North. | South. | Grand Total. | Since 1833. | Since 1861. | Since 1879. |
| 1833 | 6,109,391 | 7,369,015 | 13,478,406 | | | |
| 1861 | 7,893,584 | 8,568,987 | 16,462,571 | 22·14 | .. | .. |
| 1879 | 7,889,159 | 8,704,320 | 16,593,479 | 23·11 | 0·80 | .. |
| 1882 | 8,123,542 | 8,771,689 | 16,895,231 | 25·35 | 2·63 | 1·82 |

*Mr. H. Law.*
30 May 1883.

13,928. (*Sir John Coode.*) Will you refer us to the various percentages of increase, because some of the plans do not stretch over quite the same area of the river?—We were driven last winter from our soundings and observations by stress of weather, but I would refer you to plan No. 20.

13,929. (*Sir John Coode.*) All these percentages of increase, if I understand Plan No. 20, are between Jenningtree Point and Crayfordness?—No, they only comprise Divisions Nos. 2, 3, and 4, because we were prevented by stress of weather from taking Division No. 1. Table 10. explains it.

13,930. (*Mr. Norman Bazalgette.*) Up to 1879 they comprise all divisions?—Yes, they do up to 1879, but in 1882 we were taking them in the autumn, and the weather became so tempestuous that we were unable to complete them. Now, it will be within the recollection of the Commission that this longitudinal section of the river was put in by Mr. Mansergh, and that an arbitrary line, as I may call it, in blue was drawn from the river at Woolwich to the river in Long Reach, and then imagining that line to express properly the increased capacity which the river should have had, it showed that there were deposits at the points where the bed rose above the blue line, and that the deposit had been increasing at Crossness, and it was, therefore, said, inasmuch as the blue line represents what the river should have been, that had it not been for the outfalls, the deposit would not have taken place there. But the way in which I have examined that question is this: I have calculated the quantity of tidal water passing through each section the of river at half ebb, that being the time when average results would be obtained and the maximum velocity. I want to explain to the Commission the way in which I arrived at the quantity of water, because, of course, that is very important, and I now lay before you Diagram No. 21, which will explain the manner in which that quantity is arrived at (*Diagram No. 21 was handed in; see Appendix BF.*). I am sure the Commission will find I have not loaded them with papers, and that the diagrams are the shortest way in which I could have put the information before them, and that they will convey the best information. Diagram No. 21 is a longitudinal section of the River Thames, extending from Teddington to Gravesend, and the upper line of the blue tint there shows the level of the surface of the river at 7.10 in the morning, which was half an hour before the middle of the ebb tide at the sewage outfalls. The lower line represents the surface half an hour after half ebb. Now, pursuing the same system that we did before, and calculating the quantity of water contained in that band, together with the water coming over Teddington Weir and the different tributaries during that time, we get very accurately the quantity of water passing at any point during the middle hour of the ebb tide; and therefore we get the quantity of water passing per minute; and having the transverse sectional area we ascertain the mean velocity at each of those points. I will now put in a table which contains, first, the number of the section, the locality, the transverse sectional area in square feet, the quantity of water in cubic feet passing through the section per minute, the mean velocity of current in feet per minute, and the authority for the figures; the authorities being Mr. Shelford in 1877, Mr. Mansergh in 1878, the Metropolitan Board of Works in 1879, the Thames Conservators in 1879, and Mr. Law and Mr. Chatterton in 1879.

*Table* 11 *was handed in, and was as follows:—*

TABLE No. 11.

SHOWING the MEAN VELOCITIES of the CURRENT in the RIVER THAMES between BLACKWALL POINT and LONG REACH, during the Middle of the EBB TIDE, 3rd October 1882.

| No. of Section on Diagram No. 17. | Locality. | At Half Ebb. | | | Authority. |
|---|---|---|---|---|---|
| | | Transverse Sectional Area in Square Feet. | Quantity of Water in Cubic Feet passing through the Section per Minute. | Mean Velocity of Current in Feet per Minute. | |

The foregoing table is calculated from sections plotted from soundings, those marked S. having been taken by Mr. Shelford in 1877, those marked M. by Mr. Mansergh in 1878, those marked M.B.W. by the Metropolitan Board of Works in 1879, those marked T.C. by the Thames Conservators in 1879, and those marked L. & C. by Messrs. Law & Chatterton in 1879.

Diagram 17 (*see Appendix* BG) shows the lines of the respective sections; the horizontal line A.A. is put at an altitude above the datum line, which represents a mean velocity of 196 feet per minute; and the line, looking something like a railway section of embankment and cutting, expresses at any particular line of the section the mean velocity of the water at half ebb at that section. Taking a mean velocity of 196 feet per minute, or about 2¼ miles per hour, as about that which would keep the river clean, we then see by the parts coloured pink where the velocity is too low, and by the parts coloured blue where the velocity is high; and if we examine this section we shall find that wherever a deposit has taken place we have the pink deficiency. At Woolwich, where a very large dredging has taken place, a very large deposit has formed; and the same at Galleon's Reach; the same at the southern outfall between Halfway Reach and Barking Reach, at Erith itself, which is shown by the long pink tint extending from Rainham Creek to the River Darenth. It will be observed that when the river passes into Long Reach the velocity rises very rapidly, and of course a deposit does not take place. Instead of taking an arbitrary line, I have taken a line which expresses the same velocity all the way, and enables us really to compare these things in a reasonable manner so as to get the result, and to see at once whether the current is too fast or whether it is too slow. We consider that a river, in order that it may maintain its depth of water or its area, must be what is termed in *régime;* that is to say, in train; that its velocity shall not vary beyond certain limits, and then the river will maintain itself. But if the velocities rise and fall to the extent that they do here, and if they are also assisted by the river being tortuous and of varying width, and so forming places which the tide does not reach, deposit is inevitable and is the natural result, and not the result of the accidental proximity of those places to the sewage outfalls which are quite inadequate to produce the result even of those shoals alone. That section which has now been placed before your Lordship (*handing in Diagram No.* 14, *see Appendix* BH. (1)) is a diagram of the low-water sectional areas of the River Thames between Jenningtree Point and Dartford Creek, being that portion of the river which is in question at Erith. The dotted line shows the sectional area of the river in 1833; the pink tint shows the increased sectional area which was given between 1833 and 1861. This will convey in a better way than anything else can the enormous extent to which the sectional area was increased; and I would submit that the sectional area has increased here exactly where these very mud banks are complained of. If we now compare 1861 with 1879 in the next section diagram No. 15, *see Appendix* BH. (2), we find that this increase has still gone on at the part below Erith where the increase before had not been so great; but the river having been made larger than it could carry, the sectional area has been diminished in the part between Jenningtree Point and Erith itself. The inevitable result of the river having been enlarged beyond what it could carry is that deposit takes place. Now if we pass to the next diagram No. 16, *see Appendix* BH (3), and compare it with the previous diagram, you will find that the places where the sectional area is diminished, as shown by the brown spots, are just the same as the spots where it had been made abnormally large. Now I am laying before your Lordship a plan No. 30, *see Appendix* BJ, which shows from actual experiment the course of the current. I may explain that these currents were taken by a float, but that the float was of a different character from that employed in the experiments made by the Conservators. The objection which we took to the float in those experiments was that, owing to its very great weight, it was not amenable to the small variations of the current; that a mass like that which weighed half a ton moving with a certain velocity, if it came into a current with a diminution or accession of flow, continued to move with its former velocity; because of its *vis inertiæ*, or its *vis viva*, its rate of motion could not be suddenly changed; that has been pointed out by Professor Unwin.

[*The witness produced his own float, and explained the same.*]

It floats in this way in the water: the white float is just visible above the surface of the water, it can be seen at a great distance in the day time; and in the night in order to avoid the necessity of making your boat fast to the float, which of course destroys the accuracy of all your experiments, we have a lamp upon it, and are thereby enabled to carry on our experiments continuously; and this float answers to every change of velocity. It was with that instrument that the observations I am now going to describe were made; plan No. 30, embraces the same portion of the river as that of the contour plans, namely, from Jenningtree point to Crayfordness, and there is a little table in the corner which gives the time of high and low water upon the several occasions when the currents were observed. Upon the 23rd November the float was put into the river at three o'clock, the low water that day being at half past six, so that this was the middle of the ebb tide when the tide was running down very strongly indeed upon the northern side, the float being put in half way between the Upper and Lower Ballast Wharves at Erith, and instead of going down the river it passed up the river with a velocity of 45 feet a minute in a reverse direction to the direction of the current flowing upon the opposite side of the river. It pursued its course until it reached a point when it had in fact travelled over a distance of half a mile, it then met the current coming down and ran out upon the course shown by the line attaining a mean velocity of 99 feet a minute until it got back to Erith pier. Another float was put in upon the same day at a quarter after three in the afternoon, and therefore about the same time as the first I mentioned. That was put in opposite the Upper Ballast Wharf, and its course is shown by the uniform dotted line. It passed up the river to a distance of a quarter of a mile with a velocity of 37 feet per minute, and then turned and ran down with a velocity of 118 feet a minute, until it had got opposite the Lower Ballast Wharf, when it was taken out. Another float was put in on the 24th November just before four o'clock, or 2½ hours before low water, opposite the Upper Ballast Wharf, that passed down for a distance of about three-eighths of a mile, when it met the return tide and passed with a velocity of 127 feet a minute until it was taken out by Erith Pier. These, of course, are definite and absolute experiments; and if the Commission visit Erith at any time they will see that while the tide is running down with great velocity upon the northern side, the yachts which are situated in this bight are lying with their heads in various directions, more affected by the wind than by the tide. In addition to those consecutive or continuous float observations, you will observe a number of arrows in the river; and when I say the whole of the observations we made were during the ebb tide, and that there are a very large number of arrows there pointing up stream, you will immediately see the state of the river in that part, which is simply this,—that having been made abnormally large at this part, the river, having acquired a certain velocity in passing down to this point, cannot stop itself suddenly,—it runs through itself and would leave a vacuum, unless water went past it in the opposite direction to fill the vacuum up; that is the way in which it happens. The water having obtained a velocity and not being able to change it immediately, rushes over the northern side and would leave a hole, only that water will find its level, and, therefore, the water runs back. And we have this proposition, which I know no engineer will deny, that if you have two sections of a river near together with the same quantity of water passing and the same sectional area, the mean velocity will be the same; but that if you have a sudden

*Mr. H. Law.*
30 May 1883.

enlargement and project the water with considerable velocity through it, a portion of the water must run back, and will give you a negative quantity, in which case the law will still hold that the mean velocities are the same. This is just an experimental expression of the mathematical law, and that is the cause, as we say, of the formation of the mud banks where this eddy takes place. We say that nothing you can do, short of embanking the river, will prevent the deposit of mud taking place and it is the fact. The Conservators produced a plan at the former inquiry, which doubtless, if the Commission wish to have it, will be laid before them; it was a plan which was prepared by the late Mr. James Walker, president of the Institution of Civil Engineers at the instance of the Corporation of London, who were the then Conservators, pointing out these very facts to the Corporation, that unless the Thames were trained, deposits and shoals would take place, and laying down by a red line upon the plan the line of embankments which were to be made to prevent it. But there is another thing which contributes to this, and for which the Conservators are in a measure to blame, and it is this, they do not limit the depth and extent to which people may dredge, so long as they do not dredge sufficiently near the wharf walls or piers, or other structures to endanger their foundations. But that is a great error, because if I make any portion of the river abnormally large, I am doing a great mischief, and I am really causing shoals to form in some other part; and that is a fact which has not been sufficiently realised by those who have now the government of the river.

13,931. (*Chairman.*) I perfectly appreciate your reasoning; but I should have thought that there would have been a strong downward current upon the concave side of the river at all times of the tide?—No, it is this. Your Lordship is quite right in supposing that under ordinary circumstances the current would hug the concave side, because a body in motion tries to move in a straight line. and would be continually constrained to change its direction, but you must look at the direction in which the water approaches. The water has been thrown across from Jenningtree Point direct upon Cold Harbour Point, and the straight line in which it is endeavouring to move is that straight line (*describing the same*); it has not been deflected from the north side to the southern side.

13,932. There has not been length of reach enough to deflect it?—No, it has rushed past Jenningtree Point in a line which is nearly horizontal on the plan, and it really strikes upon the northern side.

13,933. You have tested it by experiment, have you?—Yes.

(*Chairman.*) One remembers that when one used to row up the river, one used to keep upon the convex side when one was rowing against the tide.

(*Mr. L. Smith.*) Would your Lordship ask if there has been any corresponding experiment upon the flood tide.

(*Witness.*) I am coming to that now. This was only taken the other day, and we have not yet had it lithographed; we can only hand in one copy to the Commission and one to the other side (*handing in diagram No.* 36, *see Appendix* BK). Those are experiments showing the course of the flood, and your Lordship will see that in the same way the flood runs upon the northern side, and that the float, which was put into the middle of the river, just opposite the Erith pier, where these important banks are said to begin, only moved in the course of six minutes a distance of 300 feet, or at the rate of 50 feet in a minute. You will see the course taken by the several floats, the time at which they entered, and so on, and those floats ran with the full strength of the stream, but the float put in in the middle of the stream, you will see by the short line that indicates it, did not travel fast—that it was almost slack water in the middle—that in this bight the water was slack at both ebb and flood. If that bank were taken away to-morrow the deposit would go on again until it attained a certain limit.

(*Mr. L. Smith.*) Which is the short line?

(*The same was pointed out.*)

13,934. (*Mr. L. Smith.*) That is only six minutes?—Quite so.

13,935. (*Chairman.*) There is a bank of mud there?—It is a very large mud bank.

13,936. That must have been brought there by the water?—Undoubtedly.

13,937. It would not have been brought there by the water unless the water had gone there?—Undoubtedly.

13,938. Going up and down, it must have been brought there somehow and deposited, and had some sewage with it?—No doubt it had its due admixture of sewage—the whole of the water, we will say, contains a uniform mixture of water and mud—the water which is moving upon the northern side is moving with such rapidity that it carries that mud, whereas the water upon the southern side which contains the mud drops it.

13,939. Your argument is that it is not the sewage which has done it?—That is so.

13,940. My observation only goes to show that though the sewage has not done it, yet the sewage may have had its share in doing it?—We admit that immediately.

13,941. As adding to the solid matter in the river?—Yes, that is evident.

13,942. (*Mr. L. Smith.*) The banks which are formed are partly formed of sewage, are they not?—We do not quite admit that.

13,943. (*Chairman.*) You say that if the outlets were stopped, there would be a deposit of mud at that spot?—No practical change would take place.

13,944. But you will say that if the solid matter in the sewage adds to the matter deposited in the river, some part of it may have added to the bank?—Some part has been contributed by the outfalls, no doubt, but do not let us assume that that is sewage because sewage comes out of the outfalls.

13,945. But you say that it is made up of the solid matters of the water in the river, let that solid matter come from where it may?—Yes, sewage contains two parts; you may divide it into the part which is perishable and the part which is permanent, the permanent part may go to contribute to the banks, but the perishable part will not. Now, I have a word or two to say as to the character of the mud.

13,946. (*Sir John Coode.*) Your contention is that if there had been no sewage in the river, there would still have been a deposit of mud in the bed?—Yes; and as a matter of fact there was, because we show you what it was previously to 1865.

13,947. But now you say the solid parts of the sewage contribute in a greater or less degree to the deposit of the bank?—Yes, and I think now the Commission will appreciate why I went at some length into the comparative quantities of mud which came from the sewers and other sources, because, while I do not deny that in the ratio in which these two things exist, the outfalls do contribute to form the banks; I wish to impress upon you that the ratio of the sewage to other matters is so small that the effect of it is inappreciable.

(*Mr. L. Smith.*) Your Lordship will remember that in one of the earlier reports it was said that this position of the outfalls might be an unfortunate selection because of the slack water at that point.

(*Chairman.*) Have we had evidence as to the nature of the deposit upon the banks?

(*Mr. L. Smith.*) Yes, we had Professor Heaton and Mr. Lionel Beale, who had examined it chemically and microscopically.

(*Chairman.*) Have we had anybody who has stated of what it was composed?

(*Mr. L. Smith.*) Yes, there was some evidence with regard to that.

(*Witness.*) I do not think any of their witnesses went so far as to give the percentage of sewage in any

bank deposit; they seemed to think that that was difficult to do.

(*Sir John Coode to Mr. L. Smith.*) I think the evidence you gave was rather from non-chemical witnesses who spoke of the stinking character of it.

(*Witness.*) We shall have both chemical and microscopic evidence. I have only one observation to make with regard to the float experiments. I am not going through them. I only wish, so as to justify my not going into them, to read two questions. At Question No. 8212, Mr. Baldwin Latham was asked, "If that were so, if the float had been kept in the "displaced sewage, it would have gone down at the "rate of three quarters of a mile a day," to which he replied, "Yes, if the float could have obeyed the "natural flow of the stream, which it cannot, as the "velocity in every part of the stream varies, and one "float cannot give the mean of the stream; therefore, "you get these discordant results. (*Q.*) If the float "had been a part of the sewage, as we may assume, "it would have gone down the stream at the rate of "three quarters of a mile a day? (*A.*) Yes, the total "volume would, but I am pointing out that a particle "of sewage would obey the same action as the float. "(*Q.*) The action of the floats, therefore, conveys an "erroneous impression? (*A.*) They give the range "of the tides and not the progression out of the "river." Therefore, as that is admitted, I do not propose to say anything more at all about that, but I wish to call attention to what your Lordship put very clearly in this. You said, "Supposing the float "came out of the reservoir with the sewage, one "would suppose that it would go as fast as the "sewage, and, leaving the mixing action alone, one "would suppose that it ought to go down the river at "the rate of three quarters of a mile a day. I do "not say that the sewage may not find its way up "the river, because a quantity of sewage may get "a certain distance up, and then it may stop in an "eddy, and it may be again carried up by the next "up-tide, and taken still further; but it seems to me "that what Mr. Bidder is contending for is demon-"strated," and the witness said, "I say the floats "only show the horizontal oscillation, and have "nothing whatever to do with the ordinary displace-"ment." Then Sir Peter Benson Maxwell said, "Mr. Bidder made a statement to the effect that the "sewage did go at a certain slow rate. Now either "your tables go to contradict that statement, or they "do not. If you admit that they do not then surely "the cross-examination may be very materially "shortened. Do they contradict it?" and the witness answered, "What we say is that the floats only show "the oscillation, and have nothing whatever to do "with the progress. We have already shown the "progress. We admit Mr. Bidder's argument with "regard to the oscillation, and we have given "evidence as to the mixing question, showing that "the sewage does get out of the river under "varied circumstances. (*Q.*) Then these floats do "not contradict Mr. Bidder? (*A.*) They do not. "(*Mr. Bidder.*) But nevertheless these floats are "large bodies 12 feet high, and not obeying the "flow of the water, whereas the sewage is in minute "particles in suspension and obeying every motion of "the water."

13,948. (*Chairman.*) What are you doing—are you giving us evidence, or are you reasoning upon the evidence of your opponents?—I am going to found an observation upon this—then Mr. Baldwin Latham replied, "I admit that; but still there is evidence to "show that wherever these floats have gone sea water "has gone, and wherever sea water has gone sewage "has gone, because the sea water could not have "been carried up the river past the outfalls without "carrying sewage with it;" that is the point I wanted to bring out—that, practically, the float experiments have been thrown over upon the other side with this exception, that they said that, having been put in with the sewage at the outfalls, they did arrive ultimately at Chiswick or at Putney or at Hammersmith, and then they say that wherever they went sewage might have gone too. It is important to consider whether that is so, so I have just taken out what happened to these particular floats which did go to Chiswick and I have only one word more to say about them. No. 3 float, for instance, started at low water when the sewage water would have been considerably further down the river, and after 12 days, and having travelled 538 miles, it has arrived at Chiswick; but it is hard to contend that a piece of sewage could have existed 12 days in the river, and travelled 538 miles, and still have been sewage.

13,949. How did it get up there?—By the continued oscillation.

13,950. That is what happened?—One of their floats found its way up to Chiswick, and they raise upon that the argument that, inasmuch as that represents what might have happened to the sewage, sewage might have gone there; but I am representing that the float had spent 12 days in doing that, and that it had travelled 538 miles, whereas the most persistent sewage could not do that.

13,951. Then it would have been oxidized by that time, you mean?—Yes. No. 5 float in the same way occupied 6 days, and travelled 356 miles, going to Putney Bridge.

13,952. You do not deny the possibility of the float having *bonâ fide* run up to Chiswick, do you?—I do deny the *bonâ fides* of that particular float No. 3, because I know what happened to it; but I do not wish to carry that any further.

13,953. Where was it put in?—At low-water at Barking; and I think we have some evidence of what did happen to it upon a particular day, but after what has been said upon the other side by Mr. Baldwin Latham, it would be labouring the case, and taking up your Lordship's time unnecessarily, to go any further into them.

13,954. (*Mr. L. Smith.*) When you say you have some evidence, do you mean some evidence you are going to call; is that what you mean?—No; I think it has already been before the Commission.

13,955. Then I should like you to point out some evidence which goes to show that float No. 3 was tampered with?—It was put to one of your witnesses in cross-examination.

13,956. But when you say there is some evidence as to No. 3 float, are you pointing to something that is upon the notes on something that you are going to prove?—I think it was put in cross-examination to one of your witnesses.

13,957. But I want to know, when you say you have evidence as to this particular experiment, do you mean to say that the float has been tampered with?

13,958. (*Chairman.*) I think it was an unfortunate expression of mine that led to this discussion. (*To the witness,*) You did not mean to say that it had been tampered with?—No, not in that sense.

13,959. I used the expression "a bonâ fide experiment"?—I had in my mind the fact that we had pointed to that float in cross examination. Now a good deal was said as to the comparative state of the river with the state of the river many years ago, when the water was said to be fit for drinking and making tea, and so on. Now in making the Thames Tunnel we were very much and seriously inconvenienced by the character of the ground which came down from the bed of the river into the excavation, and I have a letter of Sir Isambard Brunel, addressed to Mr. Browell, who was the analytical chemist to Guy's Hospital, another to Mr. Brand; and Dr. Faraday was consulted, and I have one or two notes of what happened upon two or three days when we had poisonous gases, and inflammable gases which came into the shield caught fire and burnt for a considerable time, and the health of our men was affected to a very considerable extent by those emanations. I propose on this point to read a note of my own made in 1839.

13,960. What do you say that shows?—It shows that the mud which came from the bed of the river at that time, was of such a character that it gave off large

*Mr. H. Law.*

30 May 1883.

quantities of sulphuretted hydrogen and other gases, one note of mine would show it to your Lordship. On the 30th April 1839, "A considerable rush of ground "took place, bringing with it every description of "river deposit and dirt, a root resembling a sea-weed "in a fresh state, oyster shells, &c., accompanied by "a very strong effluvia. The stench in clearing out "the frames was horrid, the ground thus removed was "black mud, river deposits, small coals, and masses "of black clay, with sand smelling strong of gas "refuse," that was our experience of the nature of the bed of the river at Rotherhithe at that time.

13,961. That was before the sewage was turned into the river?—Yes, that was before the sewage was turned into the river, because at that time almost all the houses were drained into cesspools, and it was an offence at common law to carry the overflow from a cesspool into a sewer, and it was not until Bramah invented the water-closet that the connexions were made surreptitously, and at last they were made so extensively that the law was altered, and from being prohibitive it was made compulsory.

13,962. I thought Mr. Edwin Chadwick was the inventor of the scheme of sewage?—No, the great fight with Mr. Chadwick was about small pipes as against large sewers. Then I will refer the Commission to the first Report of the Thames Conservators after their constitution. In the first Report, which was issued upon the 31st December 1858, the Commissioners will find a lengthy description of the state in which the river was then. I merely wish to call your attention to that. I would also call the attention of the Commissioners to a joint report which was made by Sir Joseph Bazalgette and myself and my partner upon the 15th of April 1878, in the Appendix to that Report which I think has been put before the Commission; you will find a reference to the state of the river in 1858, the letter of Mr. Faraday and a copy of the statements laid before the Lord Mayor as to nuisances arising from the docks and other matters of importance. Now upon the 7th of November 1872 (I should mention that I acted as shower upon the previous arbitration inquiry) upon that occasion I went down the river with Sir Charles Hartley, Sir F. Bramwell, Captain Galton, Mr. Pope, Mr. Bidder, Mr. Clark, and Mr. Aston; I represented the Metropolitan Board of Works, and Captain Burstal and Mr. More, represented the Conservators. We went down in the Conservator's steamer, and the Conservators had their appliances for dredging up the mud and for collecting it; they dredged up the mud wherever they pleased, and they also collected it upon the shore, and the mud so found was perfectly inoffensive. We went exactly opposite to Crossness, in the middle of the bank which is alleged to consist entirely of sewage. The mud was brought up through an instrument formed on purpose, and as I say the mud so brought up was perfectly inoffensive. We then ran down the river and took it from the banks in every direction, and after that I, as shower, challenged Captain Burstal to produce a mud of an offensive character, and he could not; and if the Commission make themselves the same investigation it will be the most conclusive proof I should think to their minds of the real state and character of the mud. No difference was able to be detected in the mud in any part of the river. I have now only one remark to make, and that is in regard to the pollution of the wells. At question 7944, Mr. Baldwin Latham suggested that this inquiry was really of great importance as affecting health, because it was possible that the wells which supplied water for drinking purposes might be polluted; he was asked, "Now passing from "that to another matter, in your judgment is the "discharge of the sewage into the River Thames in "any way likely to affect the wells in the neighbourhood," and he said, "Yes, it is." I only wish to point out that in the sections which I deposited yesterday with the Commission I showed that the water which exists in the chalk stands at a very high level of 400 feet at a distance of some miles from the river and falls with a gradual gradient towards the river, and from that I would put before you the fact that the water will run from the wells into the river and not from the river into the wells.

13,963. I was thinking of that. I was expecting you would say it, but are there no wells where the water stands at a lower level than the high-water of the Thames?—If there were that would prove incontestably that some impervious stratum of clay existed between that well and the river, and therefore, must cut off access to it, otherwise the water from the river would reach its level in that well.

13,964. That is very ingenious and rather points to this dilemma, that is to say, either the water is always higher than the level of the Thames, or else there in an impervious wall there between them, but you know the spring may be a short supply, and the consumption may be considerable, and the water might be kept down in that way?—But the cases which have been put are rather these; the proof of the influence which the tide has upon the well has been founded upon the fact that the water rises and falls in the well in sympathy with the tide, and that may very well be.

13,965. Is there any evidence to that effect?—Yes, that has not been denied, but if you consider that the water is always flowing through the chalk, if I stop that by the increased pressure of the tide, I make an artificial hydraulic ram with very slow beats and at very long intervals. I think that that concludes all I have to say.

13,966. Before you are cross-examined I should like to ask you one question. Suppose you could take the sewage 20 miles further down upon each side for nothing, would you do it?—No.

13,967. You would not?—No, not 20 miles, because you would then take it from a place where we say it does little or no mischief to a place where it would do a great deal of mischief.

13,968. Where do you mean?—At Gravesend.

13,969. But considerably below Gravesend, I would say?—Yes.

13,969*a*. Supposing it could be done for nothing, would it be a good thing to do?—Yes, if I could do it for nothing I should not hesitate to carry it down into the open sea. I have always advocated throwing it into the sea if you can.

13,970. Then it is some nuisance where it is, apparently?—No, I cannot say that it is a nuisance.

13,971. Then why would you like to take it further away?—Because I should like to see the river as pure as possible. It is necessary in the first place to define what is meant by a "nuisance."

13,972. And that is very difficult to define?—I will put it in this way. I believe that no person passing up and down the river, if they were not told that the sewage was discharged into it, would ever find it out. I will put it as high as that.

13,973. (*Sir John Coode.*) Not at any time or under any conditions?—Not unless they were to row within, perhaps, a distance of 100 yards of the outfall itself, and then their attention might be attracted to it. And I will also call your attention to this fact, that while I say the sewage is not practically appreciable there do exist and higher up the river, for instance at the entrance of Bow Creek, Messrs. Odam's works, works which I have seen within the last six months upon a fine frosty morning, with the sun shining, throwing out clouds of steam and smoke, which obscured half the river, and the stench of which was intolerable. The stench from the salicylic acid is intolerable, and I would also say that from the barges which pass down the river containing putrid bones you would see a column of visible steam rising into the atmosphere from the hold, and if you are within 150 yards, in a leeward direction, the stench is so nauseous that it is impossible to conceive anything more offensive. The men on board, I understand, do not suffer so much, because it is so hot from the putrefaction that the stench rises up directly and passes a little way off. Many of these things occur

in large rivers like the Thames, and these are nuisances, but I really consider the nuisance of the sewage is inappreciable.

13,974. (*Chairman.*) Was it in contemplation by the Metropolitan Board of Works to make another main sewer in the north with the view to preventing some of the storm overflows which now take place, only that they hold their hands till they know what will be the result of this Commission ?—No; what has happened is this, that in certain districts, and in the low parts of those districts, the sewers have been filled to an extent that, instead of receiving any more rainfall, it used to pass out into the neighbourhood. At Kennington, for instance, the great Effra sewer, which was a recognised natural brook, in very heavy rains proved insufficient to take the water, and the Board built a new sewer to carry away the storm water, and those works are being carried out and will soon be completed. But the works as to which they hold their hands till the completion of the report of this Commission are as to the enlargement of the reservoirs at Barking and Crossness so as to avoid the necessity of letting the sewage pass out during the flood or continuing so long during the ebb.

(*Chairman to Mr. Lumley Smith.*) Do not suppose that we are going to find any fault with the evidence which you have given with the view to showing that the sewers are not adequate to carry off as much rainfall as they ought to do, and that consequently there is an overflow of sewage occasionally in the upper part of the river, and indeed occasionally all the way from Hammersmith downwards; we do not complain of that; but is there any evidence that that is productive of any sensible or appreciable nuisance to anybody ?

(*Mr. Lumley Smith.*) No, but it is the foundation of an argument that the contention on the part of some of the witnesses that it is pure water which comes down to dilute the sewage at Crossness and Barking is erroneous, because it comes down already polluted with what has flowed out from the storm outflows in London, and that is the way in which we have thought it important.

(*Chairman.*) Of course when it comes down from the storm overflow it is not as good as it would be if there had not been any outfall from them; but at the same time, it comes down in increased volume evidently.

(*Witness.*) May I make one remark on that, which is this, that whether it is diluted by an enormous quantity of rain before it gets to Barking, or when it gets to Barking, is of very little consequence.

13,975. (*Chairman.*) That is the remark I was going to make; that is to say, your sewers at Crossness are discharging a less sewage mixture than they would have been doing if there had been no rainfall ?—Quite so, because the sewage of the people themselves is not affected by the rainfall; that is not increased.

13,976. (*Chairman to Mr. Lumley Smith.*) If you think it is an important matter to continue, the Commission are not going to make an interlocutory award against you in any way, but it certainly strikes us that it is not the great question that we have before us; and to say the truth, without compromising any of my brother Commissioners, it strikes me that although it would be a good thing if it were possible never to have storm overflows at all, yet the expense to which the public would be put to obviate them would be so enormous, and the amount of injury you have shown resulting from it is, if anything, so little, that it would be very difficult to say much about it.

(*To the Witness.*) I think Sir Joseph Bazalgette said it would cost 8,000,000 of money to have separate sewers, and certain expense to each house ? —In many cases it would be impossible; in any case it would mean the duplication of the system of sewers. It would cost, without making even a rough guess, an enormous sum of money.

(*Mr. Lumley Smith.*) We have rather obeyed the instructions of the Commission in not bringing any evidence as to any remedy for the evil, or how it would be done, or what it would cost; our evidence has been, no doubt, that the condition of the Thames at London has been improved enormously since this system came out, but what has been said upon the part of my learned friend is that so much pure water comes past the outfalls that it must prevent the sewage being a nuisance locally.

(*Chairman.*) I will say no more than I have done, but perhaps both sides will think of it, and they will really see that the grand question is the condition of the river between Greenwich and Purfleet.

(*Mr. Lumley Smith.*) Certainly. Now, there is such a great quantity of matter involved in Mr. Law's evidence that if my learned friend could take another witness next Tuesday, and let us take Mr. Law the week after, because the evidence cannot be given us till next Tuesday, it would be very much more convenient to us.

(*Mr. Norman Bazalgette.*) I am told that it will put the Board to extreme inconvenience, as the engineers and the various witnesses evidence is so dovetailed, to interpolate another witness.

(*Chairman.*) I cannot help thinking that that is rather a fanciful objection.

After some discussion, it was agreed that the cross-examination of this witness should be postponed till Tuesday the 12th of June.

Adjourned to Tuesday next at half-past 12 o'clock.

# THIRTY-SEVENTH DAY.

## Tuesday, 5th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
FRANÇOIS DE CHAUMONT, ESQ., M.D., F.R.S.
THOMAS STEVENSON, ESQ., M.D.

WILLIAM POLE, ESQ., F.R.S., *Secretary.*

Dr. JOHN WILLIAM TRIPE called in; examined by Mr. NORMAN BAZALGETTE.

13,977. You are a Doctor of Medicine, a member of the Royal College of Physicians of Edinburgh, President of the Society of Medical Officers of Health, and Medical Officer of Health for the Hackney District ?—I am. I have been 26 years Medical Officer of Health.

13,978. I believe for some time past you have been pursuing an investigation with a view to determine

*Dr. J. W. Tripe.*

5 June 1883.

14,001. Of course it is always possible that the people at Woolwich are being poisoned by the sewage, and that the proper quantity, instead of being 11 ought to be 1, or 2, or 3, and that the people at Greenwich are not indeed poisoned by the sewage, but by something else, is there any possibility of that?—In Greenwich there has been always a little excess of diarrhœa, there is something peculiar in the way in which diarrhœa lays hold of certain districts without a person being able to tell why. Whether it is in the soil or not I cannot say, the water in Greenwich is the same as in the other places; and yet there is the fact that Greenwich has suffered more from diarrhœa since 1866, though not to any great extent, except in the case of this particular epidemic which has been most severe, so that that 18·18 would be reduced to about 14, if you take away the excess for those four years of diarrhœa and measles, and reduced it to the average, but I have given you the facts as they stand.

14,002. (*Dr. Stevenson.*) Do you think that the density of population has anything to do with the difference in number?—Yes, but it is odd enough that the parts which are most dense in population appear to be those which have suffered least. And, perhaps, having got so far as that, I might be allowed to reply to that question as to what I thought was the cause of these results. I think that the air from the river blows out the bad air from the houses which are near, and that there is nothing injurious carried from the river to the houses, and that consequently the people are healthier in the vicinity of the river than they are away from it.

14,003. (*Chairman.*) But it is obviously consistent with that reasoning that the people might be healthier still if there were no sewage there?—That I cannot say anything about, excepting that it will be seen that the diseases which are considered to be those most likely to be caused by emanations from the river are not found in the vicinity of the river, that is the point.

14,004. That is a just remark, certainly?—If you look at the figures, it is the fact.

14,005. (*Sir John Coode.*) Can you tell us what is the proportion of dwellings along the immediate river bank to warehouses, taking Woolwich for instance?—At Woolwich I think you will find there very few warehouses.

14,006. I would like to know what is the fact with regard to the proportionate number of dwellings to warehouses immediately along the river bank compared to the area further in?—If you look at the map you will see there are a number of small streets running down to the river, and yet there has not been a single death from zymotic disease in these four years. Then if you go further on to Warren Lane, which runs down to the river, and Harden's Lane, which comes down to the gasworks, the same remark applies, as it is nearly a quarter of a mile which I take as the limit. I thought that would be a fair distance to take from the river bank.

14,007. My question referred to the belt immediately along the river bank?—I admit there is a difficulty especially in regard to Greenwich; but Rotherhithe, which I shall come to directly, will show you a fact which is very striking indeed, because there you get a line of houses right along the river. It is true it is chiefly on one side, but it runs along the whole river front, and yet in Rotherhithe Street there is only along the whole of the three quarters of a mile only one death from diphtheria.

14,008. But one sees, coal wharf, coal wharf, and so on, on the plan?—Yes, but if you refer to Erith you will see that Erith does not come down, as a rule, close to the river, even allowing for the wharves.

14,009. (*Mr. Beaumont Morice.*) And, therefore, there are few deaths?—There are wharves there, but they are at no great distance, and you have houses even on both sides in some parts.

14,010. (*Sir John Coode.*) I suppose in many cases there is a caretaker who lives upon the wharf?—I daresay, but with regard to this particular case of diphtheria in Rotherhithe Street was registered as "diphtheria peritonitis." Now it seems to me that this could not have been a death from diphtheria at all, but I put it down as diphtheria because it was entered in the return as diphtheria; but I think there are several of those deaths which ought not to have been registered as being from the diseases entered in the certificate. I think the medical gentlemen upon the Commission will admit that a death from "diphtheria peritonitis" could scarcely be considered to be a death from diphtheria.

14,011. (*Mr. Norman Bazalgette.*) If that one is eliminated, the only death from diphtheria in the neighbourhood of the river disappears?—It does.

14,012. (*Colonel Ewart.*) In your investigations at the hospitals, or otherwise, have you obtained any statistics as to cases of those diseases, because your statistics are entirely limited to deaths, are they not?—I only took out the deaths from the hospitals.

14,013. You have no statistics as to the recoveries?—I have not.

14,014. (*Sir John Coode.*) Do you think that that is a true gauge, that the ratio of deaths will give us a true idea of the ratio of disease?—I think the result of the figures of the hospitals shows that ordinarily the proportion of attacks to deaths, as a rule even, differs very little. Scarlet fever is an exception, probably, and small-pox also occasionally, because attack of hæmorrhagic small-pox cause a larger proportion of deaths than ordinary confluent small-pox. In the same way there is a kind of scarlet fever which kills before the rash comes out.

14,015. I only wanted to know the general conclusions to be drawn; is the death rate a fair criterion of the ratio of disease?—I think fairly so, because it is found from the experience of hospitals, as a rule, that there is a proportionate rate between the death and the disease.

14,016. (*Dr. Stevenson.*) Do you know any better mode of arriving at a true result?—No, I do not. You have here reliable data; whereas if you take anything else you would get into an unending mass of confusion; you would have to go to the medical men, both in and out of the district, and you would have very doubtful evidence to rely upon. I know of no evidence better than this.

14,017. (*Sir John Coode.*) Or so good?—Or so good. I shall have to point out to you my reasons for adopting a somewhat theoretical basis of calculation, namely, calculating the number of zymotic diseases to the deaths from all causes; but I will refer to that by and bye.

14018. (*Mr. Norman Bazalgette.*) Will you call attention to the Greenwich spot map now?—Yes. This area is more limited than it would have been if I had decided upon the spot map system at first. I may say that these statistics were not got out with the idea of making a spot map, and therefore perhaps you may say that the results are either more or less satisfactory, according as you may regard them, otherwise I should have extended the district in Greenwich, which is rather limited. I thought we should be able to get at the census, but there were certain difficulties at Somerset House with regard to the census, so that the only census that I have is that of the training ships; therefore it is that I adopted the percentage of zymotic disease to total deaths. Now you will see by the Greenwich map that there are wharves and quays at Greenwich. The difficulty with Greenwich is that nearly the whole of the river frontage is occupied more or less by wharves. I visited three streets at Greenwich. I thought this was the plan that would give the fairest results. But here again, in the same way as in the other case, in fact to a greater extent; the deaths at Greenwich occurred away from the river, far more than anywhere else; and it is very striking indeed, that in these four years you have but one single death from scarlet fever near the river, and that is in Bennett Street. There is one in Newcastle Street, half a quarter of a mile from the river; but in the other cases you will see there is a much larger proportion of the deaths in Chester Street, about the

middle of the area than elsewhere. It bears out precisely the same thing, but, as I say, those deaths were not got out with the idea of making a spot map. I was not satisfied with Table 1, and therefore thought I would see what evidence a spot map would give me. Now I will refer to Rotherhithe; I went to three different areas in Rotherhithe before I chose this one. I have also mentioned the long Rotherhithe Street, and pointed out one diphtheria case which I consider doubtful. You will see in that block of houses betweeen Paradise Street and Rotherhithe Street, where you get an exception to the rule, the river frontage is quite blank, it is a very poor neigbourhood, and very much crowded. You will see there has been a large number of deaths from scarlet fever in that bit of the district, and also one from diphtheria, but no death from diarrhœa or typhoid.

14,019. (*Sir John Coode.*) Princes Street also appears to be a very bad locality?—In Princes Street, which runs at right angles with the river, there were two deaths from diphtheria, one from diarrhœa, two from scarlet fever, and two from typhoid fever, it is the only instance of that kind of thing occurring; and there you see that the spots are partly distributed away from the river, and partly near to it.

14,020. (*Chairman.*) There are one case upon one side, and seven on the other?—Yes. Then in Adam Street, Albion Street, and Risdon Street, you will see that there is almost a similar kind of aggregation of disease, whereas, as I show, all along the bank, along Rotherhithe Street, there is nothing of the kind. Elephant Lane is a very poor street, but Princes Street is not so poor as Elephant Lane, where you get three deaths from diarrhœa.

14,021. (*Sir John Coode.*) Did it occur to you to make any inquiry as to what were the sewerage rarangements of the street where you had the largest number of deaths?—It did not.

14,022. It did not occur to you?—I cannot say that it did not occur to me, but the place is so spotted round about that I did not make an inquiry.

14,023. (*Colonel Ewart.*) Are they an old class of house?—They are; but Princes Street is wider than Elephant Lane in fact. I cannot account for the outbreak. I may now say that before considering the poverty of the people, and the condition of the place generally, and the number of people apparently living in the houses with their children, I came to the conclusion that the only way in which I could account for it was that the air from the river blew away the bad air which might form a *nidus* for the spread of disease. I use the term "*nidus*" advisedly, because I know no other which would give the precise impression I want to convey.

14,024. At any rate, as far as the facts go, they show that the districts upon the margin of the river enjoy a certain immunity from deaths from zymotic disease?—They do.

14,025. Can you tell me whether the number of deaths per thousand from zymotic disease varies according to the density of the population, as well as from other causes?—I got out from the supplement to the 35th Report of the Registrar-General, which is a mine of wealth to the statistician, the following table which is somewhat singular, and this is one reason why I decided to compare the deaths from zymotic disease to the deaths from all causes. The deaths from all causes and from zymotic disease of persons of all ages during the ten years 1861–70; taking the healthy districts as 100, were in all England 138, and in Liverpool 229. Of those of all ages from the seven chief zymotic diseases, the healthy places being taken at 100, there were 140 deaths in England, as against 138 from all causes, and at Liverpool 232 against the 229 deaths from all causes, so that the relation of the deaths from zymotic disease, to deaths from all causes in these ten years, is so singularly close that I think it may be taken as a reasonably fair and accurate basis for calculating the death rate. I must say that, as a statistician I was rather astonished, and very pleased to find that I was right in adopting that basis. I undertook this calculation expecting that the result might be totally contrary. The results are best shown in a tabular form as follows:—

*Dr. J. W. Tripe.*

5 June 1883.

The Number of Deaths in England and Liverpool from all Causes and from Zymotic Diseases to 100 Deaths in the healthy districts, 1861–1870—

| | Healthy Districts. | England. | Liverpool. |
|---|---|---|---|
| Deaths at all ages, and from all causes - - | 100 | 138 | 229 |
| Deaths at all ages from seven chief zymotic diseases | 100 | 140 | 232 |

14,026. (*Mr. Norman Bazalgette.*) Applying that to the selected districts, what do you say for the four years from 1878 to 1881?—The zymotic death rate in all London was 16·23 per 100 deaths from all causes; whilst in the riverine areas selected it was 12·85 in Greenhithe; 13·26 in Erith; 11·14 in Woolwich; 18·88 in Greenwich, and 23·67 in Rotherhithe. Now in Greenwich, as I have already pointed out, that excess arose from measles and from diarrhœa. The death rate from measles was 7·29 and 7·72 from diarrhœa, which, if you look at Table No. 1, you will see are enormously high as compared with the death rates from the same diseases in other districts. If the excessive death rate from measles be reduced to an average, the total death rate from these diseases would be only 13·88; but as the high death rate from measles was accompanied by a diminished death rate from scarlet fever, it would be fair to assume that the zymotic death rate in the Greenwich area would be about 14·5, or it might be as high as 15 per cent. of the total deaths, allowing for the deaths which would have taken place from other diseases if the deaths had not taken place from this one.

14,027. (*Sir John Coode.*) There is a very high death-rate from diarrhœa as well as from measles?—Yes; and I say, if you take the two into consideration the death rate will be reduced to 13·88, and if you take the average it would be 15.

14,028. (*Mr. Norman Bazalgette.*) That is as compared with 16·23 for the London death-rate?—Yes.

14,029. (*Chairman.*) There is a singular coincidence as regards the large quantity of deaths from measles and from diarrhœa at Greenwich. Does tha suggest the idea that similar causes may have produced them?—No; because diarrhœa has not prevailed to anything like that extent, except for those four years. Why it should have prevailed during those four years I cannot tell; the water supply may have been fouled during those four years for anything I can tell.

14,030. (*Dr. De Chaumont.*) You do not suggest that measles or whooping cough are connected with sewage?—No; and therefore I strike them out of my spot-map. I do not consider they are in any way connected with it.

14,031. (*Mr. Norman Bazalgette.*) I believe that the figures from deaths from zymotic disease are higher in Rotherhithe than in any other parts of London,—can you account for that in any way?—I account for it chiefly by the character of the population and the number of children, as from the Registrar-General's supplement to the 35th Report, I would mention this fact. The deaths of children under five years of age from all causes and from zymotic disease in England and in Liverpool, compared to 100 in the healthy districts from 1861 to 1870, was in England 150 from all causes and 155 from zymotics; but in Liverpool, where there is a very large number of young children, it was 262 from all causes and 343 from zymotics; of course you will remember there, the extreme density of the population and the large number of poor.

14,032. (*Sir John Coode.*) Liverpool has about the highest death-rate in the kingdom for a large town?—Yes; but the deaths under five years of age from all

*Dr. J. W. Tripe.*

5 June 1883.

causes were 262, while the deaths from zymotic diseases at the same ages were 343.

14,033. As compared with 155 for the rest of England?—Yes; so that it is evident that if you compare the two tables together as to the comparison between England and the healthy districts at all ages, and then compare those under five years, you see an enormous increase of the death-rate in Liverpool from zymotic diseases; and therefore it is that I consider the same thing has occurred in Rotherhithe,—it absolutely swarms with children, and especially the part near the river. I think I scarcely ever saw a district which was so swarming with children, and many of them without shoes and stockings. Now these children would be of the same class as those at Liverpool, and therefore one might have expected a high death-rate from that circumstance. That is borne out by the facts, inasmuch as the proportion of deaths amongst young children in Liverpool under five years of age is larger in proportion than in any other district, bearing out this fact which I have mentioned, and which I think fully accounts for it.

14,034. Does not that large death-rate in Liverpool apply to those above five years of age as well as to those below?—Yes; in all England the number of deaths under five years, from zymotics was 155 whilst in Liverpool it was 343, or more than double; and from all causes the number of deaths under five years in England was 150, whilst in Liverpool it was 262.

14,035. (*Mr. Norman Bazalgette.*) Did you hear Dr. Corfield give his evidence?—I did.

14,036. Did you hear him say that that he did not consider the high death-rate from zymotic diseases in Saint Olave's, Southwark, of which I believe Rotherhithe forms a part, was caused by the state of the river?—I heard him say that in cross-examination, and I quite agree with him.

14,037. The evidence of the spot-map corroborates that, I believe?—I believe it does fairly; I cannot say that it does to the same extent in other districts.

(*Chairman.*) What was the general effect of Dr. Corfield's evidence?

(*Mr. Norman Bazalgette.*) I think the general effect of Dr. Corfield's evidence was to show that statistics prove the opposite of what Dr. Tripe says they do.

(*Chairman.*) Did Dr. Corfield go into the figures?

(*Witness.*) I am going to criticise Dr. Corfield's evidence if you will allow me to do so. I would say, with regard to Dr. Corfield's tables, in the first place, that I look upon them as not reliable for comparison to a certain extent,—first because the deaths, which were very numerous, in the Asylums Board Hospitals from fever and scarlet fever, and small-pox,—the deaths in the Small-pox Hospital at Islington, the Fever Hospital at Islington, and the various infirmaries which are outside the metropolis,—were not distributed to the parishes from which the cases were brought. I quite admit that it would be almost impossible to have got that out for the whole of London, but it can be got to a certain extent which I shall submit to you to show to a certain extent how far these errors have crept in. There is also another thing which I think is very strong indeed in regard to cases of fever. Dr. Corfield returns all cases of fever as fever. Now simple continued fever and fevers of uncertain kind and origin, typhoid fever and typhus fever, all of which are grouped together into one figure arise from different causes, so that Dr. Corfield himself, if he had been asked, would never have said that typhus fever was caused by the same thing as typhoid fever, or simple continued fever. Typhus is simply a disease of poverty and overcrowding.

14,038. (*Chairman.*) Is it infectious?—It is highly infectious. When I say "poverty and overcrowding," I mean the necessary concomitants or attendants on poverty or overcrowding.

14,039. General insanitary conditions?—Yes, that is so. I may say here that I do not believe that the river or the drains by themselves, irrespective of germs, ever caused typhoid fever, small-pox, scarlet fever, or whooping cough; but I believe that insanitary conditions render persons more susceptible to taking the disease, and also that by producing greater debility and a bad state of the blood, owing to the blood not being properly aerated, those diseases are apt to prove more intense than they otherwise would have been. I would also point out that Dr. Corfield said that he looked upon scarlet fever as being more likely to be influenced by the river. Now, if you look at the spot-map, you will see there is very little scarlet fever near the river, except in Rotherhithe.

14,040. Did Dr. Corfield give us statistices in the same way as you have done?—Yes. Table 2 is a comparison between my statistics and Dr. Corfield's, as far as I have been able to give them. I could not go back earlier than the year 1856, because the diseases were not then published in a separate form; but I could take the years 1856 to 1865, as against 1871 to 1880. There is however a difficulty here, namely, that zymotic diseases were more prevalent in all London during the years 1856 to 1865 than in 1871 to 1880. As that prevalence ran through the whole of that period, the death-rate from the chief zymotic diseases in the years 1856 to 1865 was 4·64 for all London; against 3·83 in 1871–80 being a difference of 17·5 per cent. Now it would have been unfair towards Dr. Corfield's Tables if I had compared 1856–65 with 1871–80 without making a deduction for that increase; so I have corrected them by deducting the 17·5 upon the zymotic death-rate, for 1856–65 in order to make it compare with the death-rate for the whole of London during 1871–80. If you turn to Table 5, you will see that it includes those parts of the district of St. Olave's, which were near the water,—the riverine districts,—which were given by Dr. Corfield; and also the two sub-districts, Leather Market and St. Mary, which were not near the river, and therefore entirely out of the influence of the river. Now the zymotic death-rate is 4·46 for the district near the river, that is to say, after I have allowed for deaths in hospitals, which I have corrected as far as I could.

*Table No 5 was handed in and was as follows:*

TABLE No. 5.

Compiled by JOHN WILLIAM TRIPE, M.D.

*Zymotic Deaths.—Annual Average Results for the 10 years 1871–80.*

PROPORTIONS TO 1,000 PERSONS LIVING.

| Sub-Districts. | Small-pox. | Measles. | Scarlet Fever. | Diphtheria. | Whooping Cough. | Fever. | Diarrhœa. | Cholera. | Total Zymotic Death Rate. |
|---|---|---|---|---|---|---|---|---|---|
| St. Olave's, Southwark<br>St. John, Horsleydown<br>St. James, Bermondsey<br>Rotherhithe | 0·26 | 0·59 | 0·81 | 0·18 | 1·08 | 0·40 | 1·07 | 0·07 | 4·46 |
| Leather Market<br>St. Mary | 0·51 | 0·83 | 0·68 | 0·07 | 1·15 | 0·34 | 1·42 | 0·02 | 5·02 |

14,041. (*Chairman.*) What are we doing in St. Olave's, Southwark?—That is Dr. Corfield's table.

14,042. Suppose we do not bother about Dr. Corfield?—If you are content I will not bother about it any more, I mentioned it because it led to this,—that in the sub-districts away from the river the mortality was high, the zymotic death-rate being 5·02 as against 4·46 close to the river. I leave that to the Commission what it is worth. You will see in Table 2 that I criticise Dr. Corfield's Tables and the results I have arrived at are those which I have mentioned before.

If you follow out Table 2, you will find that as the sewage is moved away from a district, the deaths from zymotic diseases become more, and when it is taken down to other districts it becomes less in those districts; but of course I do not by any means mean to say that the sewage being poured into the river has that effect, but there is the fact.

14,043. You have mentioned this zymotic disease, but do you know what is the general health of those districts, speaking in a very general way, and not asking for figures?—I cannot answer that question, because that would entail a very considerable amount of time and labour, and even what I have ascertained has entailed a very considerable amount of time and labour, which I could ill spare.

14,044. Why are the zymotic diseases selected?—Because they are considered to be the diseases which chiefly arise from or are affected by sewer emanations or emanations of that kind. I think the whole of the medical evidence for the City has gone to the effect that these diseases are at least the best test for sewage contamination.

14,045. Lung and throat diseases would not be a test of this question, would they?—I have seen throat diseases which I think have been caused or have been made very much worse by sewer emanations.

14,046. But you could not tell us, perhaps, whether the district is generally healthy?—I can give you the figures, if it is desired, but in a general way I can say that Greenwich and Woolwich are certainly healthy. Dartford is very healthy. Gravesend is very healthy, and Hoo singularly healthy. I think the death rate there is only about 14, and yet the zymotic death-rate was very much higher in the years 1856–65, when there was no sewage there, than in 1871–80 when it was there.

14,047. So you speak well of these districts generally, and especially well in regard to zymotic disease?—Yes; the death-rates from those diseases are very low.

14,048. (*Dr. de Chaumont.*) Supposing, with regard to the condition of the waterside population in those districts, it were suggested that the emanations from the river rose over them, and blew upon the land behind, what would you say?—I cannot imagine they would be so subtle; they must have been subtle in the extreme to have been blown over in that way, except with high winds. Such a supposition is altogether contrary to all that we know with regard to the spread of zymotic disease, except diphtheria, which is the only disease that we know to be carried any distance by the wind. There is not a single other disease that I believe to be carried by the wind. Small-pox has been stated to be carried by the wind, but this is entirely contrary to my experience.

14,049. But without supposing that the disease is carried in that way, if any emanations coming from the river were blown into the districts behind, they would increase to a certain extent the susceptibility of persons to disease, would they not?—I think the effect would diminish as the square of the distance increases, inasmuch as the emanation, whatever it was, would become mixed with such a large quantity of air in being carried away. The air is considered to oxidise all these injurious emanations more or less, and so would counteract them, and then, bearing in mind the mixing of the pure air with them to any great extent, I cannot imagine that that would increase either the susceptibility to disease or the injuriousness of the emanations.

14,050. (*Dr. Stevenson.*) Are those districts flat, or do they rise directly from the river?—They are mostly flat; there is rising ground at Erith and at Greenhithe somewhat.

14,051. Greenwich would not be rising ground?—Greenwich is not.

14,052. (*Sir John Coode.*) You are aware that, taking the first four districts in your Table 5, the mean population per acre is about 93, whereas in the second table the mean population per acre is 142. Would not that affect the result in the last column?—Undoubtedly it would to a certain extent; there is no question about it, but what I have done in Table 2 is that I have compared the death-rates in the same districts, or as nearly so as possible, irrespective of that.

14,053. But my question referred to Table 5?—In Table 5 it may have had something to do with it, because the density of population in Leather Market and St. Mary is greater by about 50 per cent.

14,054. (*Mr. Norman Bazalgette.*) Did you hear the evidence given by Dr. Collingridge with regard to certain outbreaks of typhoid on board the training ships which he attributed to the influence of the river?—I did.

15,055. What have you to say as those outbreaks?—In my opinion the river had nothing to do with them.

14,056. (*Chairman.*) What did Dr. Collingridge say?—He said generally that in some instances he believed that typhoid fever was caused by the condition of the ship, especially off Greenhithe, but that as regards the vessel which was moored in the midst of the sewage stream, he believed that the outbreak that took place arose from the extremely injurious state of the river. Now the singularity about it is this. In the whole of the epidemics which occurred on board this ship (two or three of which lasted for months, while the patients were kept in the ship); when the patients were taken out of the ship as soon as they got ill and the other residents were left in the polluted stream—in the "injurious" stream as Dr. Collingridge said,—the latter remained well. In fact the only way in which the disease was checked was by taking the sick away and leaving the healthy in the midst of the polluted stream, when those who were left in the ship remained perfectly well.

14,057. (*Mr. Norman Bazalgette.*) Leaving them in the infected area, so to speak?—Precisely. Then there is another matter as regards Dr. Collingridge's evidence. If the river were injurious as producing scarlet fever, undoubtedly that would be shown by the type. Now several of the cases of scarlet fever which occurred on board that ship are distinctly stated to have been of a very mild type indeed; and with regard to the typhoid fever it is admitted that the water supply was brought from the shore in a flexible hose. Now what is there to show that some polluted water did not get in. There is no question that if polluted water were drunk, and there were typhoid fever in London, some of those who drank it might get typhoid fever; and the whole of the evidence of Dr. Collingridge, as far as I have gone into it, was to that effect. The only evidence that he produced was that he himself when he was on board his yacht suffered from sickness and diarrhœa occasionally. None of the men were stated to have suffered, only he himself. Now I know if I do not get my meals regularly and am knocking about, I am very liable myself to get diarrhœa and also dyspepsia. I will not suggest that that was the case with Dr. Collingridge, but it would certainly have had that effect upon me.

14,058. (*Sir John Coode.*) You spoke of the water having been brought to the ship in a flexible hose. I suppose that water was connected with some company's service on shore?—Yes, no doubt.

14,059. Do you suggest that the water in this service was infected?—I do not say it was so. Dr. Collingridge said in his evidence it might have been so. He said that the water was analysed, and gave different analyses at different times.

14,060. But did you not speak of typhoid fever prevailing in London, and that that might have been the cause of the disease; I did not understand your answer otherwise?—I take Dr. Collingridge's own evidence; he stated the point in his evidence; I did not.

14,061. (*Dr. Stevenson.*) Do you mean to say, with regard to the flexible hose, that there might have been a leakage from the river into the hose?—Yes,

*Dr. J. W. Tripe.*

5 June 1883.

that is what might be suggested. Dr. Collingridge mentioned the matter.

14,062. (*Sir John Coode.*) But it would surely be the other way; the leakage would be from the hose into the river, seeing the head of pressure on the hose?—I may say at once that I abandon any theory of that kind.

14,063. (*Mr. Norman Bazalgette.*) I think you have some figures which show the death-rate on board the training ships during the years 1878–81, as compared to the normal or ordinary death-rate for all England?—Yes, the census of the ships gave 1,556 persons; there were 23 women and some children, and, as far as I could ascertain, the 56 would represent the women and children.

14,064. There are three ships, are there not?—There are five ships altogether.

14,065. (*Sir John Coode.*) You had better give them to the Commission separately?—I am not quite sure whether I can give you the precise spots where they lie, but I can give you the ships separately. The "Chichester" was not used at the time of the census as a dwelling-ship at all; but that and the "Arethusa" were taken together. The "Worcester" had been there, and the "Worcester" and the "Arethusa" were taken together for one batch of boys.

14,066. (*Mr. Beaumont Morice.*) They are at Greenhithe, I believe?—They are at Greenhithe; there were 209 there then. In the "Warspite" there were 195.

14,067. (*Sir John Coode.*) Where is she?—I think she was at Grays. In the "Cornwall" there were 226; she is off Woolwich. In the "Shaftesbury" there were 347, and in the "Exmouth" 579, making a total of 1,556. I believe the number of women and young children was about 56, leaving the 1,500 for the men and boys. Now there occurred in the "Exmouth" six deaths in the four years and one in the "Warspite."

14,068. (*Chairman.*) Taking the 579 in the "Exmouth," that would be three per mil.?—It is somewhat less than that, I think.

14,069. The average death-rate is about 20 per mil. per annum, is it not?—The death-rate at the ages from 10 to 20, which I will take as the average of those on board the ship, would be 6·72 per mil. for all England.

14,070. That is a state of comparative healthiness, is it not?—I am going to point that out. On the whole, in this case it was 4·2 in the ships for four years, as against 6·72, which is the general rate for all England.

14,071. Then there must be something exceptional there, which destroys the value of the comparison. You cannot attribute it to the sewer; you cannot say the sewer has made it healthy; but here are boys under regular discipline and thoroughly well fed; does not that account for it?—No doubt it takes it out of the average; but still I think that, taking the rate of mortality at 4·2 as against 6·72, the difference of 2·50 is in excess of the margin that you can fairly allow for the good food and the regular mode of life on board these ships. Then if you look at the causes of death they are chiefly acute rheumatism, pneumonia, and phthisis. There was one death from typhoid fever on board the "Warspite," and there was a death on board the "Cornwall," as to which I told you that in the year 1879 the sick were kept on board some months, and that it was only when the patients were moved out that the disease stopped. There was one death from scarlet fever and one only, and two deaths from typhoid fever out of 19 cases; the rest were acute rheumatism and phthisis.

14,072. (*Sir John Coode.*) Are we to gather from what you have told us that the continuance of the disease was due to overcrowding; that there were under the conditions too many individuals within a given area?—That is my belief, and also partly due to the infectious nature of typhoid fever, because typhoid fever is to a certain extent infectious.

14,073. Do you think the ship was well ventilated?—No, I do not.

(*Mr. Beaumont Morice.*) It was proved by the captains of the vessels that they had given up the use of the river water in consequence of the bad effects of it.

(*Witness.*) And very wisely too.

(*Mr. Beaumont Morice.*) They did not even use it for washing the decks.

(*Chairman.*) I was desirous of knowing whether the witness was contradicting those who know better than he does; do I understand you to say that he is contradicting them?

(*Mr. Beaumont Morice.*) Yes, he is. We have called witnesses to show that an outbreak occurred at the time when this water was being used.

14,074. (*Chairman to the witness.*) I do not understand you to say that if they were to use the water, but that if they were to drink it they might make themselves ill?—I have no doubt of it.

14,075. If they used it for washing clothes, or what not, would it have any effect?—I think that if they got the water upon their hands and put them in their mouth, or were thirsty and had a drink of it; in that kind of way it would decidedly prove injurious. I do not hesitate to say so.

14,076. (*Mr. Norman Bazalgette.*) Have you in the course of your investigations also looked, as the medical officer, at the Customs and Police Reports?—I have.

14,077. Do you find any remarks upon the health of the men under the charge of the Customs and Police medical officers?—No. Dr. Dickson, in his Report for the year 1880 on the health of the Custom House officers, says that the difference in the health and condition of the two divisions of the force, viz., of London and Gravesend, is the natural result of the great difference that exists in age, duties, and mode of life of the different officers employed, and he does not refer to any alleged injurious effect of the river.

14,078. I believe there is a passage in his Report for 1878 which is valuable?—Yes, he says at page 108 of his Report for 1878, "The proportion of "zymotic and febrile disease is, as usual, very "small."

14,079. Can you tell me how many men are engaged, on the average, in the Customs?—The table shows about 1,000 people; 860 are engaged on the river, 150 being employed as Thames Police, whom Dr. Browning spoke so strongly about.

14,080. Have you looked at the Reports of Mr. Holmes, the chief surgeon of the Thames Police?—I have.

14,081. What does he say about the health of the Thames Police?—He gives a list of the chief causes of death, which were pneumonia, rheumatism, and so on. He does not say a word in corroboration of what Dr. Browning says, although he is the chief surgeon, and Dr. Browning could not have reported to him what he said here, or else it would have appeared in that Report.

14,082. Is Mr. Holmes confirmed by Dr. Gayton's evidence before the Royal Commission?—Yes, Dr. Gayton gave evidence before the Royal Commission respecting small-pox and fever hospitals, and in reply to Question 2695 he said, "A well-arranged "deck" (this hospital ship was moored off Greenwich) "appears to afford plenty of opportunity for the "construction of an excellent ward, and well suited "in every respect for the treatment of small-pox "patients; and, as the amount of fresh air is "practically unlimited, it leaves little to be desired. "I think, moreover, that statistics in a few years will "show that cases treated on the Thames have done "infinitely better than on land"; that is Dr. Gayton's evidence; he gave his evidence last year, and referred to the ship in 1881.

(*Chairman.*) Of course there is fault found with the water up to Chiswick or Teddington Lock, for aught I know; but there is not much fault found with the water at Greenwich, as I understand.

(*Mr. Beaumont Morice.*) Not comparatively.

(*Witness.*) Now, Dr. Collingridge also stated that, with the exception of the typhoid fever outbreak, and the scarlet fever outbreak, the health generally of those on board the ships was very good.

14,083. (*Mr. Norman Bazalgette.*) Now, Dr. Browning, who gave the evidence you have quoted, was medical officer of health for Rotherhithe, was he not?—Yes, and he has published some Reports.

14,084. Have you examined his Reports? — I have.

14,085. What do you find in his Reports?—In his Report for 1880–81, or in that very year for which he produced certain statistics; he said, "We must re- "member that our neighbours and ourselves having "better food, drinking water, wages, lodgings, and "sanitary surroundings than most rural working "people, and breathing an atmosphere, which, thanks "to our river, park, and docks, is less polluted than "that of most cities, ought to be quite as successful "as country folks in raising young families." Now, they are not; they lose a large number of children. The reason is, that it is a densely crowded part; the children die, as I have shown you from the statistics of Liverpool, at a far more rapid rate under five years of age than they do in the country. Therefore, Dr. Browning should not have expected that living in the small houses that they do, and in courts and alleys, and with bad food many of them, they should be able to bring up their families in the same way as people can do in the country.

14,086. Do you find that the death-rate of Rotherhithe, as shown by Dr. Browning's own Reports, compares favourably with the death-rate of London?—Decidedly, I do.

(*Chairman.*) How high up the river are you going to take us.

(*Mr. Norman Bazalgette.*) This is Rotherhithe, my Lord. I am asking Dr. Tripe about this, because evidence has been given on the other side about it.

(*Chairman.*) If people give useless evidence upon the other side, what is the necessity of calling witnesses to contradict it.

(*Mr. Norman Bazalgette.*) After your expression of opinion, my Lord, I will not pursue it.

Cross-examined by Mr. Beaumont Morice.

14,087. With regard to the spot maps, which you have put in, I will take you first to that which you mentioned first, namely, Erith. Now, is it not the fact that along the foreshore, from the National School to the lower Ballast Wharf, there are very few houses?—There is not a very large number.

14,088. Upon the side fronting the river, of West Street, how many houses would you say there are?—It is some six months since I was there; there are two rows of houses, if I remember rightly.

14,089. But what I want is this; along that space from the National School to the lower Ballast Wharf, is it not nearly all marsh land? — I do not know whether it is marsh land; it is, with the exception of two or three rows of houses, open country.

14,090. Then there are very few houses, I may take it, upon the river side of West Street?—Not a large number.

14,091. Is that the case, taking the foreshore of Erith generally to Erith Pier?—It is crowded pretty well from the lower Ballast Wharf to the turn of High Street; it is a continuous row of houses from Cross Street.

14,092. Would you kindly follow me; is there not a succession of wharves along the foreshore, from the lower Ballast Wharf to Erith Pier?—Yes; there is a number of wharves, but on the other hand, part of it is quite open; you have wharves and gaps.

14,093. Taking the part further from the river, where you put the spots, and where you find the deaths have occurred, is not that a much more populated part than near the foreshore?—Than close to the foreshore, undoubtedly it is, but it varies considerably; Avenue Road, for instance, is not very much built upon, but some of the roads are.

14,094. Take Cross Street and High Street; are not those the populous parts? — Yes, and in High Street you will notice there is only one death.

14,095. Then I may take it that, according to this map, the parts where the deaths have occurred are the more populous parts of Erith?—To a certain extent, that is so.

14,096. I may take that as a fact, may I not?—Wheatley Terrace, which is much nearer to the river, where there were no deaths from zymotic diseases, is better populated than Manor Road, where a death from typhoid fever, and another from diphtheria, and a death from diarrhœa occurred.

14,097. Take Parkspring Place and Queen Street, are not those thickly populated with a great number of small houses?—They are.

14,098. (*Sir John Coode.*) When you say Wheatley Terrace is "better populated," do you mean inhabited by a better class of people, or that it is more thickly populated?—It is more thickly populated. I should say it is about the most densely populated part of the whole, and no deaths from zymotic diseases have occurred there.

14,099. And you put no deaths in the Bexley Road, between the "Wheatley Arms" and the spot by the Police Station?—There is one death between the Police Station and the river.

14,100. Are not the houses in the road fairly apart, and of better quality?—They are of better quality, and the same with the Queen's Road.

14,101. I may take it that the parts further from the river, where these deaths have occurred, are portions where the houses are small and densely populated?—No, certainly not, in Manor Road the houses are, as far as I remember, of a better class than some of those in the front.

14,102. But you told me that to a certain extent that was so in the case of High Street and Parkspring Place?—No doubt High Street is a very mixed street, poor and others together, but they are most of them of the tradesman class, and inhabited by what I should call comfortable people.

14,103. Now take the next, Greenwich?—The Greenwich frontage, I have already explained it, is to a great extent wharves.

14,104. (*Chairman.*) Can you say, speaking generally, whether the two or three cases in Erith that you have put, as you may call it, near the river, show a larger or smaller or equal per-centage to the population where they arise with the other cases which are more distant from the river? — I should say certainly that, taking the whole river frontage, the proportion is less. I do not mean that the population is less; I mean that the deaths, in proportion to the population, are less.

14,105. (*Mr. Beaumont Morice.*) Now, with regard to Greenwich; nearly the whole of that river frontage is wharf, is it not?—To a great extent; I have already said so in my examination-in-chief.

14,106. (*Chairman.*) The expression "close to the river" has been used once or twice before. I suppose there are very few places where the houses are actually upon the river, so that you could drop anything out of the window into the river; there is always a road or something between, is there not?—Yes, Greenhithe is the nearest, I think; that is, closest to the river.

14,107. (*Mr. Beaumont Morice.*) You have very few spots upon the riverside of Chester Street, have you?—No, although some of those streets comprise a very low class of houses.

14,108. I see you have "waste land" upon the right-hand side?—Yes, and to the left, a short distance off, is the hospital; I have not taken that in.

*Dr. J. W. Tripe.*

5 June 1883.

14,109. Is there any high ground at the back of this map?—Yes, there is Greenwich Park, and there is also rather a dense population both in the old Woolwich Road and Northumberland Street; those are decidedly densely populated. Chester Street is also densely populated, and so, in fact, are the whole of those streets.

14,110. Now, I will ask you, between Chester Street and the river, is there anything like a correspondingly dense population to what there is at the back of Chester Street?—Yes; that part of Marlborough Street between Chester Street and the river, the whole of Bennett Street, Newcastle Street, Kitson Terrace, is densely populated. Little Marlborough Street is a little dirty court, where you would have thought there would always have been some disease of the kind, and there is not one instance of a zymotic death.

14,111. Then you have the Stone Yard, and then you come to the Lime Kilns, which take up a large portion of the space?—The map shows that there is nothing kept back.

14,112. But there is a large space taken up by works of some kind?—There is.

14,113. Would not that rather interfere with your theory as to the deaths being greater away from the river than near it in a similar population?—There is no population there to suffer along the wharves.

14,114. But I was not talking about the wharves, but of Chester Street?—But there have been no deaths at all in four years between Chester Street and the river, where the population is.

14,115. But you would not say that there is anything like as dense a population there as there is behind?—Yes, I do. As far as the streets themselves are concerned, the streets at the back of Chester Street seem to be more respectable than those streets which are nearest the river.

14,116. Could you give me any ratio as to the population behind Chester Street to that between it and the Thames?—Scarcely; but I should say there might be two as regards the population between Chester Street and the river, and three behind, but there is a difficulty about the census, so I could not give it accurately.

14,117. Now, with regard to the Woolwich map, the Woolwich river frontage is nearly all either wharves or workshops, or works of some kind, is it not; that is to say, there are gasworks at each end, to begin with; they cover a large space of ground, do they not?—They do.

14,118. Then there are all the workshops in the square near the steamboat pier?—Yes, that is so.

14,119. Then there are one or two large spaces near Market Hill; do not those different works which you have mentioned take a large part of the space between the High Street and the river?—They occupy some space.

(*Chairman.*) Take Rodney Street. Rodney Street is not on the river, do you say?

(*Mr. Beaumont Morice.*) I have not said that it is immediately upon the river.

14,120. (*Chairman to the witness.*) How far back would it be from the river?—It would be about 70 feet back.

14,121. (*Chairman.*) Is not that close enough to be poisoned? How near would you put it?—Of course, I can see there is one street close.

14,122. But I am taking the whole body?—In Nile Street, which runs to the river, there is no death at all. Then I would point out strongly that, as regards Rope Yard Rails and Cannon Row, all of which are identical as regards the class of houses, the spot maps show that the bulk of the disease is situated rather at the back than in the part near the river.

14,123. (*Mr. Beaumont Morice.*) After all, none of this map is far off the river?—Very little of this map is more than a quarter of a mile off the river.

14,124. Then I see you have seven spots on this part between the High Street and the river. Now what I want to ask you is this:—Can you give us any idea of the population between High Street and the river, compared to that between High Street and the rest of the map?—I should say there would be one-third the number in that part next the river to two-thirds behind.

14,125. (*Chairman.*) Are there twice as many on the south side of High Street as there are upon the north side?—I should think so.

14,126. Do you know Woolwich well?—I have been down there three or four times, for the purpose of coming to a fair estimate.

14,127. Do you know that the density of Woolwich is one-fourth that of London?—I cannot say precisely what is is.

14,128. Have you been through all these streets behind High Street?—Yes; I took the whole block from Powis Street, and followed Powis Street right out to the end.

14,129. I am not talking of Powis Street?—I went into every street, court, and alley upon the plans, and I know every site. I adopted every reasonable means of coming to a fair conclusion.

14,130. I am sure you have done that. But what I mean is, looking at the admitted density of the population of Woolwich, do you mean to say, that taking all the marks which appear upon your spot map between High Street and the river frontage, there are only twice as many people living behind High Street as there are between High Street and the river?—I think so; including High Street, of course.

14,131. Which side of High Street, both sides?—I took both sides.

14,132. (*Chairman.*) Which do you put High Street in?—I put High Street in the river area.

(*Chairman.*) Is not this really too microscopic?

14,133. (*Mr. Beaumont Morice.*) I will not press it any further. (*To the witness.*) With regard to the density of population, does scarlet fever increase with any reference to that?—Yes, scarlet fever, I should say, especially.

14,134. Do you know of any comparison between the death-rate from scarlet fever in Woolwich and London?—Yes; Greenwich and Woolwich were 1·03 for the 10 years. I should expect that the Woolwich rate would be far below that of London.

14,135. But do you know as a fact whether it is?—(*After referring.*) In Woolwich, for scarlet fever from the year 1871 to 1880 the rate was ·61, and in London it was ·60.

14,136. So that they are practically the same?—Yes. That is taken from Dr. Corfield's tables.

14,137. Do you know the difference between the density of population in the one and the density of population in the other?—Yes, I can give you that. The density of population for Woolwich is 11·8, and for London 46·9.

14,138. I will not ask you about Rotherhithe; but you have stated that, oddly enough, the densest places seemed to suffer the least. Are you still of that opinion?—I do not think I said so; if I did say so, I did not mean it.

14,139. You do not think so?—No, certainly not.

14,140. Then you think the densest places are the worst?—The densest places, as a rule. I have stated it very plainly. As regards Liverpool, you have 363 deaths under five years of age to 100 deaths from zymotic disease in the healthy districts, where the population is less than one to the acre.

14,141. You mentioned Liverpool. You know that Liverpool has a very high death-rate?—Yes, some years ago, viz., in 1874, it was 32, but in 1882 it was only 26·5 per 1,000.

14,142. Do you know how they get their water supply?—No, I do not.

14,143. Do you know that they have drained all the cesspools below Liverpool?—I do not know anything of the drainage of Liverpool, or of the water supply.

14,144. You have not been able to ascertain the ordinary cases of disease and illnesses which have

taken place in those parts where you have taken the death-rate?—I have not worked it out. It would require to be gone into at such a length that I did not attempt it.

14,145. So you have only taken the death-rate?—That is so. I can give it you, if you want it, out of some books, but I have not got it out myself. I have only the Registrar-General's Returns.

14,146. You have told us that your theory with regard to the better state of the houses near the river is that the air from the river blows through them, or blows the bad smells away; that is always the case, is it not, near a river, or near the sea?—Yes. I believe that Glasgow is pretty nearly the same as London, and that the river there is rather worse than it is near London.

14,147. That would always follow, would it not, near a large stream, or near the sea?—The River Liffey, at Dublin, is a very important exception. All round the Liffey, in Dublin, diseases of this class are very rife indeed, and a very high rate of mortality indeed prevails.

14,148. (*Chairman.*) Is that so, indeed; where the tide comes up?—It is in Dublin itself.

14,149. But the Liffey is a very narrow stream?—It is.

14,150. And filthy?—Yes, it is filthier than the Thames.

14,151. (*Sir John Coode.*) The river walls are high in Dublin, and, therefore, the river is not so open to the influence of the currents of air?—That is so.

14,152. (*Mr. Beaumont Morice.*) You mentioned it as an exception; is it not the fact that the river itself, however large or small it be, is in a filthy condition?—It is filthy in the extreme. It is not a fair illustration to compare the Liffey with the Thames in any way whatever.

14,153. Therefore, if you had a river larger than the Liffey, which is in a filthy condition, similar results might follow?—I am not prepared to say any "ifs" at all. I would rather content myself with what I know.

14,154. (*Chairman.*) I suppose there are parts of the Liffey within the city where the sewage is not oxygenated at all; are there not?—I should think there are.

14,155. (*Mr. Beaumont Morice.*) You stated that when the sewage was taken away from the district the death-rate decreased?—Yes, I say that that is a fact.

14,156. Do you know that, since the sewage has been taken away from Upper London, the death-rate has decreased?—It has decreased all over London. It has not been confined to the vicinity of the Thames.

14,157. But in the vicinity of the Thames it has decreased?—It has decreased. I stated that the decrease in London had been 17·5 per cent. in the 10 years from 1871 to 1880, taking London all through.

14,158. As a fact, the death-rate has decreased?—Yes, it has.

14,159. And when the sewage is taken into a district at first the death-rate had increased?—No, the death-rates have decreased in the district below the outfalls as compared with the 10 years from 1856 to 1865. It was higher in 1856–65 than it was in 1871–80.

14,160. But when it was first taken down, before your data, did it not increase?—There is a gap in the data between 1866 and 1871. That I cannot give you, because I have not got it.

14,161. Those are the very data that I want. Do you know when the sewage was taken down?—Yes, I remember very well. I was born in London. I have shot Old London Bridge, and I remember the Thames very well. In fact, I often cross at Gravesend and take a bath there, because it is a very pleasant bath at Gravesend.

14,162. Have you anything to show whether the death-rate increased when first the sewage was taken into the lower districts?—No, I do not think there is any relation between the two things, to tell you the truth.

14,163. But you have no such data?—I have none.

14,164. Would not the state of health of the lower districts, even after the sewage had been taken down, depend upon the seasons?—No doubt, and therefore I say, I do not attribute much importance to those statistics, extending, as they do, over an immense area, but these spot maps I look upon as most important, and the statistics in my Table 1 as next in value.

14,165. Then you do not attach any importance to the statistics upon the point?—I do not attach any great importance to the statistics of the Registrar's districts upon the point. I think that Dr. Corfield's tables and mine upon the point are of equal value, and I leave it to the Commission to say what that value is.

(*Chairman.*) What do you wish to show?

(*Mr. Beaumont Morice.*) That at first there was an increase in the death-rate in the low districts, though it may have decreased subsequently?

(*Chairman.*) And that the present decrease is due to this, that the mischief is still going on, but that it is countervailed by the wet seasons?

(*Witness.*) If that were so, the only way I could understand it would be that when the sewage was first taken down it killed off so many that it left so many less to be killed afterwards.

(*Mr. Beaumont Morice.*) Last year and the year before were very wet years, and there were not the amount of complaints that there were previously.

(*Chairman.*) The witness does not know that?

(*Witness.*) No, I do not.

(*Sir John Coode to Mr. Beaumont Morice.*) When you say "when the sewage was first taken down," what do you mean? for one year, two years, or three years; because it is rather indefinite.

(*Mr. Beaumont Morice.*) I meant for the first two or three years, without tying the witness to any particular year; but the witness cannot give us any data at all.

(*Witness.*) 1877, I think, was rather a healthy year?

14,166. (*Mr. Beaumont Morice.*) There are a great many cases of poor people who have illnesses, but who do not die, which would not come under your notice?—No doubt, people may have illnesses and not die. I cannot say anything about the number of cases of disease. I have already explained that I could not get at the cases of disease, but if river had any influence whatever, it would necessarily show itself in the death rate.

14,167. Would that death rate show all the cases of poor people who die?—Yes, because I traced out the deaths from zymotic disease in these districts. I followed them out in the hospitals and everywhere I could.

14,168. I suppose a sick person might be taken to Guy's Hospital?—Guy's Hospital does not take in infectious cases. But I have been to all the hospitals for infectious diseases, and I went to the Greenwich Infirmary. I got at all those who had died there from this district.

14,169. There are hospitals which take the infectious cases of the district?—Yes, there are.

14,170. Did you go to such hospitals?—I did.

14,171. Did you enquire what cases had been brought from Greenwich or Rotherhithe?—Yes, from those particular areas, but from nowhere else. To every one of those hospitals I have been to ascertain the deaths of people from those particular areas.

14,172. You not only ascertained those who died in houses and the local hospitals coming from there, but those who died in hospitals elsewhere coming from there?—I did.

14,173. (*Sir John Coode.*) You think you have gone far enough afield?—Yes, I do.

14,174. (*Mr. Beaumont Morice.*) You said that Dr. Corfield had not distributed those who had died elsewhere into different parishes?—Yes.

*Dr. J. W. Tripe.*

5 June 1883.

14,175. If he had done as you suggest he ought to have done, would it not rather have told against the case of those whom you represent by making the death rate greater along the riverine districts?—Not the riverine districts alone, they all would have suffered equally. I would give you some idea as to the extent. In Stepney, first of all——

14,176. But that is rather too far up for us?—Shall I take Greenwich.

14,177. Yes, take Greenwich?—There were nearly 300 deaths put in with the Greenwich mortality which ought not to have been there, and as regards some of the other districts there were nearly the same number left out that ought to have been there.

14,178. Why do you say they should not be in Greenwich?—Because people died in the "Atlas" ship and in the small-pox hospital in Greenwich, whose illness did not originate in Greenwich, and who did not reside there before death.

14,179. Take the Northfleet district?—But Northfleet has nothing at all to do with the metropolis.

14,180. Could you give me the figures of Northfleet?—No, I cannot, because it is a sub-district.

14,181. Let me ask the question generally. If Dr. Corfield had distributed the deaths in parishes, as you say he ought to have done—— ?—No, excuse me, I did not say he ought to have done.

14,182. Upon your principle then, I will say, would it not have made the death rate in the riverine districts very much greater?—No doubt it would, but it would have made the death rate in the adjoining districts also greater, they would have shared in it to a certain extent.

14,183. Did I understand you to say something about the death rate amongst the Jews?—No, I did not say it, but their death rate is singularly small from zymotic diseases.

14,184 I thought you accounted for the high death rate in Rotherhithe by reference to them?—No, I never referred to them at all.

14,185. With regard to the outbreak of fever in those training ships, do you know whether it is at all attributable to the water brought from the shore?—Dr. Collingridge went into that question; and he had some little doubt in the matter, and there were two analyses of the water given which differed rather considerably. The first analysis, as far as my recollection goes, showed a larger amount of impurity than the second.

14,186. Have you any knowledge of your own about it?—I have none.

14,187. Do you know the pumping at the Essex Waterworks on the Essex shore?—Yes, I do.

14,188. Do you know that before the waterworks were established the wells contained a good deal of salt?—No, I do not. I do not know anything about the analyses.

Re-examined by Mr. Norman Bazalgette.

14,189. Your spot maps, I think you told me, were compiled for the years 1878 to 1881, were they not?—Yes.

14,190. Therefore they do not include last year, the wet year, when my learned friend says that few complaints were made of the river?—No.

14,191. Do they include the year 1881, when we had an exceptionally hot summer?—Yes, they do.

14,192. Do you know that in July 1881 a temperature of 97° was reached?—It was 96·5 at my house.

14,193. At any rate, the maps include that exceptionally unfavourable year, and they do not include that exceptionally favourable year that my learned friend has mentioned?—That is so. I made them out as fairly as I could.

14,194. Now about the margin of the river. Can you tell how the density of population of the river along the margin compares with the density of population back from the river?—In most instances I should say the density was greater near the river, inasmuch as the houses are comparatively small, and the rooms are small and fully occupied, so that the cubic space for each person, which is the chief matter, in my opinion, with reference to the overcrowding, would be greater in the houses near the river than farther away.

14,195. When you have wharves and warehouses, do you generally find a narrow street, part of which is occupied by small dwellings?—Very frequently.

14,196. But, generally speaking, along the margin of a river, do you find that the rooms are small and the houses are small, and much over-crowding in consequence?—Yes, certainly.

14,197. Upon the whole, do you find the margin of the river enjoys a singular immunity from death from zymotic disease?—Yes, certainly I do.

The witness withdrew.

Mr. John Holmes Groves called; examined by Mr. Norman Bazalgette.

*Mr. J. H. Groves.*

14,198. You are a Greenwich waterman, I believe?—I am.

14,199. Were you employed by Messrs. Law and Chatterton to take soundings of the river?—I was.

14,200. Where were you on the 16th October last?—On the north bank in Erith Rands.

14,201. Who was with you?—A young man of the name of Gadsdon.

14,202. Anybody else?—Yes, a young gentleman belonging to the Board.

14,203. What were you doing; were you in a boat?—No, I was upon the river bank.

14,204. What were you doing?—I was laying out sections to take soundings across the river; we were driving the pegs.

14,205. Did you see a boat containing two men with one of the Corporation floats?—I did.

14,206. What do you remember about it?—I made the remark to Mr. Gadsdon that I thought, according to the position of the boat, she must be attached to the float.

14,207. Was the tide flowing up?—Yes, the tide was flowing up.

14,208. Was there a strong east-south-east wind blowing?—Yes, there was a strong east-south-east wind blowing at the time.

14,209. Did you actually see that the float was attached to the boat?—I could not swear that. I only went by the position of the boat. My opinion was that, if the float was not attached to the boat, the velocity of the wind would have taken the boat right away from the float altogether.

14,210. When you saw them were they moving together?—Both were moving together.

14,211. (*Chairman.*) Had they not got any oars out, or anything?—Nothing of the kind.

14,212. (*Sir John Coode.*) About what was the height of the gunwale of the boat above the water surface, speaking generally?—About 18 inches.

(*Chairman.*) Did the boats with the floats have any drag out to drag over the water, that is to say, in order to prevent them going faster than the floats?

(*Mr. Beaumont Morice.*) No, there were no drags out, nothing of the kind.

14,213. (*Mr. Norman Bazalgette to the witness.*) Do you remember the 19th October last?—I do.

14,214. (*Chairman.*) Well, what happened at last. Did the boat and the float go out of sight?—They went out of sight.

14,215. Up the river?—Yes, up the river.

14,216. Was the tide flowing at the time?—Yes, the tide was flowing.

14,217. And the wind blowing rather up the river than not?—Yes, there was an east-south-east wind blowing up the river.

14,218. When did they get out of sight?—About a quarter of an hour after I saw them.

14,219. (*Mr. Norman Bazalgette.*) Did you see the float tilted at the time?—I could not swear that.

14,220. (*Sir John Coode.*) Were the boat and the float in the same relative position to each other for the whole of the quarter of an hour while they were in sight?—They were.

14,221. About what distance was the boat from the float?—It might have been about two feet.

14,222. (*Chairman.*) You could not see any attachment?—I could not.

14,223. How came they not to blow on to the Essex shore, because an east-south-east wind would blow them on to the Essex shore?—When I saw them they were to the south of mid-channel.

14,224. Did they blow over to your side?—No, they went to mid-channel; as they came up towards Erith.

14,225. Where were you?—I was on the north bank.

14,226. But in what part of the river?—I was upon Erith Rands, below Erith.

14,227. (*Sir John Coode.*) Did you see them upon the bank, following the boat?—No.

14,228. Then, as the boat got up the river with the float, you could not tell that the boat and the float were constantly about two feet from each other; but what you mean, I suppose, is that when they passed you they were about two feet apart?—Yes, as far as I could judge, when they passed me.

14,229. (*Chairman.*) Was the float ahead of the boat, or after, or abeam, or what?—It was ahead of the boat.

14,230. (*Mr. Norman Bazalgette.*) Was the boat fouling the float?—No.

14,231. But how was that?—The boat was going astern up the river, and the float was fastened to the bow of the boat.

14,232. (*Chairman.*) If they had not been fastened together, they would have parted; that is your notion?—They would have parted.

14,233. (*Mr. Norman Bazalgette.*) Do you remember the 19th of October last?—Yes.

14,234. Where were you then?—I was in my boat.

14,235. At what time in the morning was this?—6.15 a.m.

14,236. (*Chairman.*) Going back to the 16th, where were the men; seated in the boat?—They were sitting down in the boat, I believe; they were out of my view.

14,237. Had they no oars out at all?—There were no oars out at all.

14,238. They were out of your view?—The men were; they were sitting down in the boat.

14,239. (*Sir John Coode.*) If they were out of your view, they must have been lying down, I presume, unless they were sitting in the bottom of the boat?—In the bottom of the boat, I presume, they were.

14,240. (*Mr. Norman Bazalgette.*) Now you told us you were out about a quarter-past six in the morning of the 19th of October?—Yes.

14,241. (*Chairman.*) What time of the day was it that you have been speaking of?—It was in the morning: it was light.

14,242. And you could have been seen?—Yes, I could have been seen.

14,243. (*Mr. Norman Bazalgette.*) Then Gadsdon was with you in your own boat when you were out, was he not?—Yes.

14,244. What was the tide doing?—The tide was ebbing.

14,245. And how was the wind?—The wind was south-east.

14,246. What did you observe?—I observed one of the Corporation floats with a boat, the float being attached to the boat.

14,247. (*Sir John Coode.*) Then it would be just daylight; it would not be broad daylight, would it, at that time?—Yes, it was quite broad daylight.

14,248. (*Chairman.*) Where were you then?—I was in my own boat on the river.

14,249. How far were you from them?—I was about 20 yards, perhaps.

14,250. (*Sir John Coode.*) Were you there for the purpose of following them and watching what they were doing?—Not then; I was on my road down to Erith.

14,251. (*Mr. Norman Bazalgette.*) The sun rose on that morning at 6.32; it was a quarter of an hour before sunrise. (*To the witness.*) Did you actually see the float attached to the boat on this occasion?—I did see the float fastened to the boat on that occasion.

14,252. What was it fastened with?—A small line.

14,253. Was it ahead of the boat or behind the boat?—It was ahead of the boat.

14,254. Was the boat stopped by the wind?—It was.

14,255. Did you recognise the men on board?—I did.

14,256. Who were they? What were their names?—Mears and Whiting.

14,257. To go to another occasion; do you remember the 29th of October last?—I do.

14,258. Have you some memoranda there?—I have (*producing a pocket book*).

14,259. Did you take some memoranda at the time?—I did.

(*Chairman.*) Would you allow me to see them?—(*The same was handed to the noble Chairman.*)

14,260. These memoranda do not notice that a float was attached to the boat?—No.

14,261. This is only a memorandum, is it, of what you did upon that day?—That is all.

14,262. You have not mentioned that they had got their floats in a suspicious way, have you?—Not upon that occasion.

14,263. Did you upon any occasion?—No, I never noted anything of that kind.

14,264. You were only making memoranda of your own work?—Yes, that was so.

14,265. (*Mr. Norman Bazalgette.*) Now, upon the 29th October at 5.30 a.m., where were you?—I was on Greenwich Pier.

14,266. Where had you just come from?—I had just come off the water.

14,267. What did you see?—As I was walking on Greenwich Pier, I saw a boat nearing Greenwich Pier, and as it was nearing the pier I found it had a float attached to it, and two men rowed alongside Greenwich Pier and made the boat fast along with the float.

14,268. Who were the two men?—Tanner and Long.

14,269. Did you see the float actually attached?—I did.

14,270. What was it attached by; a rope?—A small line.

14,271. When they made their boat fast to Greenwich Pier, what did they do?—Went on shore.

14,272. How long did they remain on shore?—Twenty-five minutes.

14,273. What did they do then?—They came back, got into the boat, and towed the float out into mid-stream, and let go the float, and then let it drop down the river.

14,274. Having been on shore 25 minutes?—Yes.

14,275. (*Chairman.*) You knew this was wrong, I suppose, did you not?—I knew it was quite wrong.

14,276. When did you mention it to the gentlemen who have called you now; to Mr. Chatterton or anybody else?—I used to make a report every week.

14,277. Of such matters as these?—Yes, of such things as these.

14,278. Do you mean to say that you reported this in November, because you must have reported this nearly at the time it happened. To whom did you actually report it?—To Mr. Chatterton.

*Mr. I. H. Groves.*

5 June 1883.

14,279. But these men have been called as witnesses. Mears, I think, has been called.

(*Mr. Lumley Smith.*) No, he was not actually called, but his name was frequently mentioned.

(*Chairman.*) You can call him if you like.

(*Mr. Lumley Smith.*) If your Lordship pleases.

(*Mr. Norman Bazalgette.*) Mr. Peregrine Birch was cross-examined as to this.

(*Sir John Coode.*) He was cross-examined in some considerable detail, if I remember rightly.

(*Mr. Norman Bazalgette.*) At question 9793 you will find he was asked, "Were Mears and Whiting employed upon October the 17th at 6.15 a.m.?" To which he replied, "Yes, they were."

(*Chairman.*) Was he asked anything about this labour-saving practice of fastening the float to the boat?

14,280. (*Mr. Norman Bazalgette.*) This was in the cross-examination of Mr. Birch, and Mr. Birch was asked this question, "During the time the experi- "ments were going on, was any information ever "given to you by my learned friend's clients of any "misfeasance on the part of the men?" To which he replied, "Certainly not." (*To the witness.*) Now, where were you on October 30th?—In my boat.

14,281. Had you anyone with you?—There were four other men.

14,282. Whereabouts were you?—I was going up what we call Tripcock Reach, on my way home.

14,283. Which side of the river?—To the south of mid-channel.

14,284. What did you come upon?—We came upon a boat very close to the shore.

14,285. What was in the boat?—Two men were in the boat. As we came close to the boat, I could see that there was a float very close to the boat. We went past the boat first, and I thought I would be sure and be correct to see who the men were, so I put back with my boat, and when we put back alongside this boat both men were asleep, and the float in a sort of lying down position, as if it were touching the ground.

14,286. It was stationary, at any rate?—Yes.

14,287. Did you see it attached to the boat?—Yes, I did.

14,288. (*Sir John Coode.*) If the float was stationary, the boat must have been stationary too?—It was.

14,289. Then, if the boat was aground, it acted as a mooring to the boat?—It was in an entirely slack tide.

14,290. (*Mr. Norman Bazalgette.*) You say the men were asleep, did they have a sail over them?—They had a sail over them.

14,291. Did you speak to them as you went by?—Yes, we called out, and when we got no answer we listened a minute, and put back in order that we might be really correct to know who they were.

14,292. (*Sir John Coode.*) Did you ascertain who they were?—Yes; directly I heard the voice of the men, I knew who they were.

Cross-examined by Mr. Lumley Smith.

14,293. Your name is Groves, is it?—It is.

14,294. What are you by profession?—I am a licensed waterman.

14,295. I do not quite understand this; were you in the service of the Metropolitan Board of Works?—Yes, at the time.

14,296. You were regularly engaged by them, were you?—I was not regularly engaged. I had been engaged, on and off, 19 years.

14,297. But at that particular time, the 16th and 19th October, am I to take it that all through October, or about that time, you were engaged by the Metropolitan Board of Works?—I was.

14,298. What were you engaged to do?—My first engagement was to watch the float operations of the Corporation.

14,299. That is what you were set to do, to watch the float operations of the Corporation; when was it that you were ordered to that first?—I never made a note of it.

14,300. Did you begin making notes immediately you were engaged?—I did not.

14,301. How soon did you begin?—Only when I saw anything wrong on the part of the men employed on behalf of the Corporation.

14,302. However, you were to watch the floats and to report anything that you saw wrong?—Yes, I was.

14,303. What is this black book; is it a memorandum of what you saw from day to day?—Yes, it is.

14,304. I see you saw something wrong upon the 17th; when does it begin, the 17th of what month?—I do not know.

14,305. Cannot you tell from memory what month this is, because the book begins at 1 p.m. upon the 17th, and I want to know what month that is?—I quite forget.

14,306. Just look at the book (*handing a book to the witness*), and tell me what month it is; is that in October, or when. (*The witness referred to the book.*) Can you tell me when you were first paid, would that give you any idea?—No; I do not remember.

14,307. You were to watch the floats—here are a couple of pictures of floats—are they pictures of floats that you put in this book here?—To the best of my ability, I did them.

14,308. And this you put upon the title page, so that you knew exactly what you had to look for?—Yes, I did.

14,309. You were told what you had to look for, and you made these pictures?—I saw them myself upon Greenwich Pier.

14,310. The "Toby" was Mr. Birch's tug, was it not?—Yes, it was.

14,311. You had general instructions, had you, to put down anything you saw wrong?—No.

14,312. Were you instructed to report anything that you thought wrong?—Not at all.

14,313. What then?—To say anything about the floating operations.

14,314. What did Mr. Chatterton want to know?—He wanted to know if the men employed acted anything that was wrong.

14,315. I see this entry in your book, "At 1 p.m. "on the 17th, the Corporation tug 'Toby' came along- "side at Greenwich Pier with three new tide floats, "8" (something I cannot read), "made of pitch pine, "13 feet long. Watermen and gentlemen appeared "to be quarrelling on board the tug"; that was the first thing you saw that you thought wrong; what did you put that down for—their coming alongside with new floats and quarrelling—what did you put that down for; did Mr. Chatterton want to know that?—No.

14,316. Then why did you put down about Mr. Birch and his friends quarrelling on board the tug; can you tell me why you put that down?—I cannot tell you.

14,317. Was not it because you were to put down everything that attracted your notice about the floats?—No.

14,318. Was that put in to accompany the picture of the floats?—No.

14,319. The next memorandum I see is, "18th, "Corporation tug 'Toby' abreast of Greenwich Pier." This must have been in September. "19th. Went "down to Crossness, fixed tide gauge upon the jetty "end—saw the tug 'Toby' come up to Greenwich— "no floating operations on that day—strong wind "from north-east. Harbour master with steam "launch." Then, as I understand, the 17th was the day the float operations began. Do you remember the

day the "Toby" came up with the three new tide floats and the men quarrelled; was that the first day they went in, I want to know?—I do not remember.

14,320. Do not you know whether it was September or October you began watching the floats?—I think it must have been in September.

14,321. Then you watched all through September; there is an entry on the 24th?—Yes.

14,322. I think you have memoranda about the floats right through that month; all these entries refer, do they not, to the floats; that is so, is it not?—I am sure I do not know.

14,323. (*Sir John Coode.*) Do you understand the question?—Yes.

14,324. (*Mr. Lumley Smith.*) All these entries refer, do they not, to the Corporation float experiments?—Yes, they do.

14,325. (*Sir John Coode.*) Do they refer to anything else besides the Corporation floats?—I think you will see a few entries about fish or anything like that.

14,326. (*Mr. Lumley Smith.*) You mention the fish, that was with a view to this inquiry, was it; were all these things in the book things that you were to tell Mr. Chatterton?—Not the whole of them.

14,327. What was there that he was not interested in?—He is only interested in regard to the float operations.

14,328. What about the fish that you were telling us of; you are not a fish merchant, are you?—No.

14,329. What was that about the fish?—To test the water.

14,330. For the purpose of this inquiry?—Yes.

14,331. Then everything in this book is for the purpose of advancing the Board of Works case in this inquiry?—Yes, that is so.

14,332. I see some of the floats you follow down, and you have down the hours and minutes at which they went down all the way. When you followed the floats you made the entries carefully?—Yes, I did.

14,333. Now we come to the 16th of October; first of all, I suppose you have shown this to Mr. Chatterton; is there any entry at all about any one of these four occasions upon which you saw the float being treated as you describe. There is nothing in this book, I take it, about it; is there?—I used to make a report once a week of whatever I saw.

14,334. Is there anything in this book which is at all a memorandum of the occasions which you have been telling us about to-day?—Yes, there is.

14,335. Will you point it out to me, please, taking first of all, the 16th of October?—That is the one (*handing the book to the learned counsel*).

14,336. "Erith Rands, 16th, 1 p.m. Boat driving "up with flood tide, wind east-south-east strong, "watermen's boat fast to float No. 4." Now then I see you make a note of the number, these floats were all numbered, were they not?—I believe the Corporation floats were all numbered.

14,337. (*Sir John Coode.*) How do you know this was No. 4 float; was the "No. 4" on the float visible to the naked eye, how did you know it was not No. 3, or No. 2?—After we had done our work, I passed this float up at Blackwall, and then I saw the number.

14,338. (*Mr. Lumley Smith.*) Anybody could see the number; the number is a big number, is it not?—Yes, it is a large number.

14,339. Is it stuck upon the float?—Yes, it is.

14,340. And upon the boat too, is it not?—No, it is not.

14,341. Are you sure of that?—Yes, I am sure.

(*Mr. Baldwin Latham.*) They had a painted flag in the front of the boat, with the number upon it corresponding with the number of the float, and upon every pier a notice was posted about them.

14,342. (*Mr. Lumley Smith to the witness.*) There was a big number upon the boat, upon the flag?—Yes, upon the flag or upon a tin flag.

14,343. So that anybody could read it?—Yes, it represented a flag.

14,344. Another was on the 16th October, was it not?—Yes.

14,345. At what time in the day?—1 p.m.

14,346. Where were the men who were in the boat then; was this memorandum made at the time?—Yes, it was.

14,347. Just tell me why you have put the 16th of October in the book several pages after the 1st of November, and several pages after the 29th of October?—I do not know the reason why. I did it so irregularly.

14,348. But I find entries taken on the 29th of October, and the 25th of October, and then comes the 16th of October; how came you to put that in two pages after the 29th?—The book is not in a regular way in any part of it.

14,349. (*Sir John Coode.*) Were those notes made day by day as the events occurred?—Yes, they were.

14,350. That is to say, what happened to-day you would make a note of this evening?—Yes, or at the time.

14,351. But some time during the day upon which the occurrences took place?—Yes, at some time of the day.

14,352. (*Mr. Lumley Smith.*) Will you explain to me why you do not go regularly through the book; if this page was blank, then why should you have stuck in the 16th after a lot of blank pages?—I do not know why I should have done it.

(*Sir John Coode.*) He says he made them day by day; if that is so, it would be a mere irregularity.

(*Mr. Lumley Smith.*) Then it comes to be a question how far this is to be relied upon.

14,353. (*Sir John Coode to the witness.*) Can you tell me why you did not put in the 16th after the 15th?—I cannot say.

14,354. Can you say positively that this was made day by day?—It was made at the time.

14,355. That what occurred to-day was not entered to-morrow or the day after to-morrow?—What occurred to-day is entered immediately after it occurred; upon the day it occurred.

14,356. Did you do so in every instance?—Yes, in every instance.

14,357. Are you quite sure of that?—I am quite sure of that.

14,358. (*Mr. Lumley Smith.*) Now upon this 29th of October, what time of day would it be when you saw this float brought to Greenwich Pier?—5.30 a.m. I think it was.

14,359. What sort of float was it that was brought?—It was a small float; one of the bucket floats as they used to call them.

14,360. Not one of the bigger floats?—No, not one of the big floats.

14,361. Which of the other occasions were big floats?—The two other occasions were the large floats.

14,362. Which were those; the 16th and 19th October?—The 16th, and 19th, and the 30th.

14,363. That is three occasions; were they all large floats?—Yes.

14,364. What was this fish you mentioned? You put some eels in, did you not?—Yes, I did.

14,365. And the eels died, did they not?—Yes, they did.

14,366. (*Sir John Coode.*) Were they in a healthy state when you first got them?—Yes, they were.

14,367. Where did you get them from?—From one of the Dutch vessels at Billingsgate, lying off Billingsgate Market.

14,368. (*Mr. Lumley Smith.*) Before I pass from the floats, can you give me the number of the one that you saw Mears and Whiting in?—I cannot.

14,369. Now on the 30th of October at Tripcock Reach, when the two men came to the shore in a boat asleep, what was the number of that one?—I do not know. It had no number.

*Mr. J. H. Groves.*
5 June 1883.

14,370. (*Sir John Coode.*) Was this one of the boats belonging to the Corporation?—Yes, it was.

14,371. How do you know that, if it had no number on?—No number on the float.

14,372. If there was no number on the float or on the boat, how did you know it was a Corporation boat?—I knew the men.

14,373. Upon this particular occasion?—Yes, upon this particular occasion.

Re-examined by Mr. Norman Bazalgette.

14,374. It is suggested to me that you are mistaken in saying that that was float No. 4; are you quite certain of it, or are you just speaking from memory.

(*Sir John Coode.*) It is important to know whether this was a Corporation float.

14,375. (*Mr. Norman Bazalgette.*) I think you told us that you identified the number of the float afterwards at Blackwall?—I passed the float at Blackwall, and I must have taken that one to be the one I saw attached to the boat.

14,376. Are you certain that the one you saw at Blackwall was the one you saw attached to the boat?—I cannot say for certain.

14,377. Do you recollect putting some eels at Greenwich in a box about six feet under the water for Mr. Chatterton?—I do.

14,378. Did you let them float down the river with the tide?—I did.

14,379. Where did they go to?—Down to Erith.

14,380. Did you then let them come back again?—I did, past the southern and northern outfall.

14,381. Did you let them come back upon the flood?—I did.

14,382. How did they get on?—They were all very well when I reached Greenwich.

14,383. Did the eels look any the worse for their voyage?—I think there was an improvement in them.

14,384. (*Sir John Coode.*) Did you clear the box out at Greenwich?—No, I kept them there.

14,385. What became of them after that?—They remained there.

14,386. But for how long?—They remained there over two months.

14,387. You moored the box to something?—I made it fast properly to a mooring place.

14,388. (*Mr. Norman Bazalgette.*) You left the box there for two months, did you?—I did.

14,389. And the eels remained alive the whole time?—Yes, they did.

14,390. Were they the same eels as had made the voyage past the two outfalls?—Yes.

14,391. What became of the eels eventually?—Some person or other took them away, or something broke the box up.

14,392. Were those the eels that you were speaking of just now, when you said that they died?—No, they are not the same ones. I got a fresh lot for them; they were put in at Erith.

14,393. Where were they put in at Erith?—At the "Castalia."

14,394. How long were they there?—They were there about seven weeks.

14,395. Did they die after the seven weeks?—Yes.

14,396. They were seven weeks off the "Castalia," and then they died?—Yes, they were off the "Castalia."

14,397. (*Sir John Coode.*) Where is the "Castalia"?—Just below Erith.

The witness withdrew.

*Mr. C. H. W. Grundtvig.*

Mr. Conrad Henry Walter Grundtvig called; examined by Mr. Norman Bazalgette.

14,398. You are a pupil of Messrs. Law & Chatterton?—I am.

14,399. And a student at the Institution of Civil Engineers?—I am.

14,400. Were you upon the river upon the 16th of October?—I was.

14,401. What were you doing?—I was putting in pegs upon the north shore for the purpose of taking sections.

14,402. What did you see while you were doing that?—I saw a boat passing up the river just above, in a line with a place called Anchor Bay. A boat was going up the river stern foremost, with a float attached to the bow.

14,403. (*Sir John Coode.*) What boat was that?—The boat I could identify as a Corporation boat, first on account of the float, and secondly on account of the red flag which she had at the stern.

14,404. Was there any number on the flag?—I could not see that; the flag was lying down in the boat.

14,405. (*Mr. Norman Bazalgette.*) Did you see the line by which the thing was attached?—I could not.

14,406. For what reason did you think it was attached?—The float was slightly inclined.

14,407. You were out again on the 19th, were you not?—I was not.

(*Sir John Coode.*) It does not necessarily follow that because the float was inclined it was attached to the boat.

14,408. (*Mr. Norman Bazalgette.*) Did you upon the same occasion observe another float?—I did.

14,409. What was the other float doing as compared with the one that you say was being towed?—When I observed the former the boat was going up first broadside and the oars were out; the boat kept on whirling about, so the men had to use their oars in order to keep back to the float; the float of course was going up the river after them; in the latter case the float and the boat kept close together the whole way for a period of about a quarter of an hour while I watched them.

14,410. (*Sir John Coode.*) Did you follow the boat up the river further?—No. I was on Coldharbour Point, and I could see them as they swept round the point.

14,411. (*Mr. Norman Bazalgette.*) Which of the floats was going the fastest?—The second one, I should think.

Cross-examined by Mr. Lumley Smith.

14,412. When you were out on the 16th October, what time of the day was it?—About one o'clock.

14,413. Who was with you?—The waterman, Groves, and another man named Gadsdon.

14,414. What is the occasion that you speak of when you mention two floats?—The 16th October.

14,415. That is the only one?—Yes.

14,416. Let me see if I understand. First of all the thing was slightly inclined, and you also say you could see some other float?—Yes.

14,417. In one case the float was going up the river about as fast as the boat, and in the other case the boat seemed to go up fastest?—In the first case the boat went up at some distance from the float, and

in the second case I followed the second boat up for a period of a quarter of an hour, and the float and the boat kept quite close together; I could hardly see daylight between the float and the boat.

14,418. Was that the float that you were speaking of when you said it was inclined, or was it a different one altogether?—It was the second float that was inclined.

14,419. First you say you saw one that was slightly inclined?—No, that was the second float.

14,420. How many did you see altogether on that day?—Two.

14,421. The one which was slightly inclined was the one which you watched; was that the one which kept close to the boat or not?—It was the one which kept close to the boat which was inclined. *Mr. C. H. W. Grundtvig.* 5 June 1883.

14,422. That is your reason for thinking it was attached, though you saw no line attaching it?—No, only the wind was blowing very strongly, and it was broad daylight.

14,423. Still this was one o'clock in the day, and the men were not asleep?—No, they were not.

The witness withdrew.

JAMES EDWARD PETRIE called; examined by Mr. NORMAN BAZALGETTE.

14,424. You are a Greenwich waterman, are you not?—I am. *J. E. Petrie.*

14,425. What were you doing on the night of Sunday, 15th October?—I was watching No. 6 float.

14,426. What time were you watching her?—I commenced at 10 minutes past 9 on the Sunday evening, and proceeded to Bow Creek; it was low water then. Then when the tide turned we went up the river.

14,427. Were you near Millwall Pier at 12.50, that is to say, at 10 minutes to 1 on Monday morning?—Yes.

14,428. Was the tide going up?—It was.

14,429. In what direction was the wind?—East-north-east.

14,430. Did you see the men who were in charge of No. 6 float do anything?—Yes.

14,431. What were they doing?—They were fast to the float; it blew a strong wind.

14,432. Whereabouts was it fastened to the boat?—It was fastened to the main thwart of the boat.

14,433. You saw the line that fastened it to the boat, did you?—Yes, there are five thwarts to the boat, and it was fastened to the middle one.

14,434. Was the boat dragging the float?—Yes.

14,435. Did you see the number of the float?—Yes.

14,436. How far did you go up with them?—I went as far as Fulham.

14,437. What happened to it; did the tide turn?—Yes.

14,438. Did you go back with them?—At 4.40 the tide turned.

14,439. Did you go back with them?—I stopped till the tide turned, and then I came back with them.

14,440. How far did you go back with them?—As far as Greenwich. I accompanied the float through Battersea bridge, and then it became daylight.

14,441. (*Sir John Coode.*) Were you near to them all this time?—I was close to them. I had to be close to them on account of putting down every place the float passed, so I had to keep close to them all the time, and when we came through Battersea bridge, there being a strong wind and tide, they had to slip the float from the boat, because there was such a current that very likely the float might have knocked a hole in the boat.

14,442. (*Mr. Norman Bazalgette.*) And you say it was daylight there?—Yes, it was.

14,443. Do you know what the names of the men who were on board?—Yes.

14,444. What were their names?—One was named Long and the other Hampshire.

14,445. Did you make a note at the time of what you saw?—I did.

14,446. Have you got that with you?—I have a note of all the driving; I did not make a note of the other circumstances.

14,447. (*Sir John Coode.*) Are those the identical notes that you made at the time?—No, they are not.

14,448. Where is the original?—With regard to the sheet I had on the Sunday night, and early Monday morning, it rained so all night that it would be impossible for anybody to make out anything from it, except myself, so I had to copy it myself, and these (*producing some slips*) were copied from it the next day.

14,449. When the float was going up stream, was it hurried up by the wind?—Yes, the boat would hurry it up, because the boat was athwart the tide and the wind would have great effect upon it.

14,450. Did you have to use your sculls all the time, to keep your boat back to the float?—Yes, I had.

14,451. Coming down with the tide, was the float retarded by the wind?—No, coming down with the tide, the float would come much faster than the boat; we had to row sharp to keep pace with the float then.

Cross-examined by Mr. LUMLEY SMITH.

14,452. How many days had you been out watching this float; was this the first day you went out?—No, it was not.

14,453. How long had you been out?—I think something like a fortnight, to the best of my recollection.

14,454. Were you always watching No. 6 float, or were you watching some of the others?—Yes; I think No. 6 float I was watching for a fortnight.

14,455. Were there the same men in the Corporation boat?—Two of them were, but there was one changed sometimes.

14,456. There was always on board one man during the whole time.

(*Sir John Coode.*) I understand two out of the three had been there the whole time.

(*Witness.*) There were three men out of four; there were two in the boat at a time, and Long and Tanner, I think, were the two men at first, and Hampshire, I think, was put in Tanner's place.

14,457. How many men were there in the boat at one time?—Two in their boat, but only one in our boat.

14,458. (*Mr. Lumley Smith.*) You were following the float and putting down the time at which it passed each place?—Yes.

14,459. And that you did every day?—Yes, I did.

14,460. And night too?—Yes; I did not do it night and day. I was relieved the same as the rest.

14,461. But whenever you were there you did it?—Yes, I did.

14,462. And they knew you were doing that?—Yes.

14,463. They knew you were watching them?—Yes, no doubt they did.

14,464. This you wrote out the next day; you did not write it out that night, but you wrote it out the next day?—Yes.

14,465. Why did you not make a note of having seen this boat fastened to the float; why did not you

*Mr. J. H. Groves.*
5 June 1883.

14,370. (*Sir John Coode.*) Was this one of the boats belonging to the Corporation?—Yes, it was.

14,371. How do you know that, if it had no number on?—No number on the float.

14,372. If there was no number on the float or on the boat, how did you know it was a Corporation boat?—I knew the men.

14,373. Upon this particular occasion?—Yes, upon this particular occasion.

Re-examined by Mr. Norman Bazalgette.

14,374. It is suggested to me that you are mistaken in saying that that was float No. 4; are you quite certain of it, or are you just speaking from memory.

(*Sir John Coode.*) It is important to know whether this was a Corporation float.

14,375. (*Mr. Norman Bazalgette.*) I think you told us that you identified the number of the float afterwards at Blackwall?—I passed the float at Blackwall, and I must have taken that one to be the one I saw attached to the boat.

14,376. Are you certain that the one you saw at Blackwall was the one you saw attached to the boat?—I cannot say for certain.

14,377. Do you recollect putting some eels at Greenwich in a box about six feet under the water for Mr. Chatterton?—I do.

14,378. Did you let them float down the river with the tide?—I did.

14,379. Where did they go to?—Down to Erith.

14,380. Did you then let them come back again?—I did, past the southern and northern outfall.

14,381. Did you let them come back upon the flood?—I did.

14,382. How did they get on?—They were all very well when I reached Greenwich.

14,383. Did the eels look any the worse for their voyage?—I think there was an improvement in them.

14,384. (*Sir John Coode.*) Did you clear the box out at Greenwich?—No, I kept them there.

14,385. What became of them after that?—They remained there.

14,386. But for how long?—They remained there over two months.

14,387. You moored the box to something?—I made it fast properly to a mooring place.

14,388. (*Mr. Norman Bazalgette.*) You left the box there for two months, did you?—I did.

14,389. And the eels remained alive the whole time?—Yes, they did.

14,390. Were they the same eels as had made the voyage past the two outfalls?—Yes.

14,391. What became of the eels eventually?—Some person or other took them away, or something broke the box up.

14,392. Were those the eels that you were speaking of just now, when you said that they died?—No, they are not the same ones. I got a fresh lot for them; they were put in at Erith.

14,393. Where were they put in at Erith?—At the "Castalia."

14,394. How long were they there?—They were there about seven weeks.

14,395. Did they die after the seven weeks?—Yes.

14,396. They were seven weeks off the "Castalia," and then they died?—Yes, they were off the "Castalia."

14,397. (*Sir John Coode.*) Where is the "Castalia"?—Just below Erith.

The witness withdrew.

*Mr. C. H. W. Grundtvig.*

Mr. Conrad Henry Walter Grundtvig called; examined by Mr. Norman Bazalgette.

14,398. You are a pupil of Messrs. Law & Chatterton?—I am.

14,399. And a student at the Institution of Civil Engineers?—I am.

14,400. Were you upon the river upon the 16th of October?—I was.

14,401. What were you doing?—I was putting in pegs upon the north shore for the purpose of taking sections.

14,402. What did you see while you were doing that?—I saw a boat passing up the river just above, in a line with a place called Anchor Bay. A boat was going up the river stern foremost, with a float attached to the bow.

14,403. (*Sir John Coode.*) What boat was that?—The boat I could identify as a Corporation boat, first on account of the float, and secondly on account of the red flag which she had at the stern.

14,404. Was there any number on the flag?—I could not see that; the flag was lying down in the boat.

14,405. (*Mr. Norman Bazalgette.*) Did you see the line by which the thing was attached?—I could not.

14,406. For what reason did you think it was attached?—The float was slightly inclined.

14,407. You were out again on the 19th, were you not?—I was not.

(*Sir John Coode.*) It does not necessarily follow that because the float was inclined it was attached to the boat.

14,408. (*Mr. Norman Bazalgette.*) Did you upon the same occasion observe another float?—I did.

14,409. What was the other float doing as compared with the one that you say was being towed?—When I observed the former the boat was going up first broadside and the oars were out; the boat kept on whirling about, so the men had to use their oars in order to keep back to the float; the float of course was going up the river after them; in the latter case the float and the boat kept close together the whole way for a period of about a quarter of an hour while I watched them.

14,410. (*Sir John Coode.*) Did you follow the boat up the river further?—No. I was on Coldharbour Point, and I could see them as they swept round the point.

14,411. (*Mr. Norman Bazalgette.*) Which of the floats was going the fastest?—The second one, I should think.

Cross-examined by Mr. Lumley Smith.

14,412. When you were out on the 16th October, what time of the day was it?—About one o'clock.

14,413. Who was with you?—The waterman, Groves, and another man named Gadsdon.

14,414. What is the occasion that you speak of when you mention two floats?—The 16th October.

14,415. That is the only one?—Yes.

14,416. Let me see if I understand. First of all the thing was slightly inclined, and you also say you could see some other float?—Yes.

14,417. In one case the float was going up the river about as fast as the boat, and in the other case the boat seemed to go up fastest?—In the first case the boat went up at some distance from the float, and

in the second case I followed the second boat up for a period of a quarter of an hour, and the float and the boat kept quite close together; I could hardly see daylight between the float and the boat.

14,418. Was that the float that you were speaking of when you said it was inclined, or was it a different one altogether?—It was the second float that was inclined.

14,419. First you say you saw one that was slightly inclined?—No, that was the second float.

14,420. How many did you see altogether on that day?—Two.

14,421. The one which was slightly inclined was the one which you watched; was that the one which kept close to the boat or not?—It was the one which kept close to the boat which was inclined. *Mr. C. H. W. Grundtvig.* 5 June 1883.

14,422. That is your reason for thinking it was attached, though you saw no line attaching it?—No, only the wind was blowing very strongly, and it was broad daylight.

14,423. Still this was one o'clock in the day, and the men were not asleep?—No, they were not.

The witness withdrew.

James Edward Petrie called; examined by Mr. Norman Bazalgette.

14,424. You are a Greenwich waterman, are you not?—I am. *J. E. Petrie.*

14,425. What were you doing on the night of Sunday, 15th October?—I was watching No. 6 float.

14,426. What time were you watching her?—I commenced at 10 minutes past 9 on the Sunday evening, and proceeded to Bow Creek; it was low water then. Then when the tide turned we went up the river.

14,427. Were you near Millwall Pier at 12.50, that is to say, at 10 minutes to 1 on Monday morning?—Yes.

14,428. Was the tide going up?—It was.

14,429. In what direction was the wind?—East-north-east.

14,430. Did you see the men who were in charge of No. 6 float do anything?—Yes.

14,431. What were they doing?—They were fast to the float; it blew a strong wind.

14,432. Whereabouts was it fastened to the boat?—It was fastened to the main thwart of the boat.

14,433. You saw the line that fastened it to the boat, did you?—Yes, there are five thwarts to the boat, and it was fastened to the middle one.

14,434. Was the boat dragging the float?—Yes.

14,435. Did you see the number of the float?—Yes.

14,436. How far did you go up with them?—I went as far as Fulham.

14,437. What happened to it; did the tide turn?—Yes.

14,438. Did you go back with them?—At 4.40 the tide turned.

14,439. Did you go back with them?—I stopped till the tide turned, and then I came back with them.

14,440. How far did you go back with them?—As far as Greenwich. I accompanied the float through Battersea bridge, and then it became daylight.

14,441. (*Sir John Coode.*) Were you near to them all this time?—I was close to them. I had to be close to them on account of putting down every place the float passed, so I had to keep close to them all the time, and when we came through Battersea bridge, there being a strong wind and tide, they had to slip the float from the boat, because there was such a current that very likely the float might have knocked a hole in the boat.

14,442. (*Mr. Norman Bazalgette.*) And you say it was daylight there?—Yes, it was.

14,443. Do you know what the names of the men who were on board?—Yes.

14,444. What were their names?—One was named Long and the other Hampshire.

14,445. Did you make a note at the time of what you saw?—I did.

14,446. Have you got that with you?—I have a note of all the driving; I did not make a note of the other circumstances.

14,447. (*Sir John Coode.*) Are those the identical notes that you made at the time?—No, they are not.

14,448. Where is the original?—With regard to the sheet I had on the Sunday night, and early Monday morning, it rained so all night that it would be impossible for anybody to make out anything from it, except myself, so I had to copy it myself, and these (*producing some slips*) were copied from it the next day.

14,449. When the float was going up stream, was it hurried up by the wind?—Yes, the boat would hurry it up, because the boat was athwart the tide and the wind would have great effect upon it.

14,450. Did you have to use your sculls all the time, to keep your boat back to the float?—Yes, I had.

14,451. Coming down with the tide, was the float retarded by the wind?—No, coming down with the tide, the float would come much faster than the boat; we had to row sharp to keep pace with the float then.

Cross-examined by Mr. Lumley Smith.

14,452. How many days had you been out watching this float; was this the first day you went out?—No, it was not.

14,453. How long had you been out?—I think something like a fortnight, to the best of my recollection.

14,454. Were you always watching No. 6 float, or were you watching some of the others?—Yes; I think No. 6 float I was watching for a fortnight.

14,455. Were there the same men in the Corporation boat?—Two of them were, but there was one changed sometimes.

14,456. There was always on board one man during the whole time.

(*Sir John Coode.*) I understand two out of the three had been there the whole time.

(*Witness.*) There were three men out of four; there were two in the boat at a time, and Long and Tanner, I think, were the two men at first, and Hampshire, I think, was put in Tanner's place.

14,457. How many men were there in the boat at one time?—Two in their boat, but only one in our boat.

14,458. (*Mr. Lumley Smith.*) You were following the float and putting down the time at which it passed each place?—Yes.

14,459. And that you did every day?—Yes, I did.

14,460. And night too?—Yes; I did not do it night and day. I was relieved the same as the rest.

14,461. But whenever you were there you did it?—Yes, I did.

14,462. And they knew you were doing that?—Yes.

14,463. They knew you were watching them?—Yes, no doubt they did.

14,464. This you wrote out the next day; you did not write it out that night, but you wrote it out the next day?—Yes.

14,465. Why did you not make a note of having seen this boat fastened to the float; why did not you

*J. E. Petrie.*

5 June 1883.

write that down?—I thought it was not required, because it was one thing continually, the whole flood tide, I might say.

14,466. They always did it every day, did they?—No, I do not say that.

14,467. What do you mean?—I say the whole flood-tide.

14,468. Then why did you not put down upon your note that the men tied the float to the boat the whole of that flood-tide?—I could recollect it.

14,469. But you were to report it to the Metropolitan Board of Works?—I was.

14,470. Then why did not you put that down?—Because I could recollect it.

14,471. (*Sir John Coode.*) Did you report weekly to the Board?—I used to report when I had done my drive to Mr. Groves, and then Mr. Groves used to send the report in to the Board, I think, every week.

14,472. If I understand you accurately, you made these observations on 14 days previously to the 16th of October; had you previously observed any irregularity in the way of making the floats fast to the boat?—No.

14,473. Previously to that the thing had gone on correctly?—Yes, it had gone on properly.

(*Sir John Coode.*) I should like to know what these weekly reports that were sent in contained.

(*Mr. Norman Bazalgette handed in a report made by Groves to Mr. Chatterton.*)

14,474. (*Sir John Coode.*) This appears to be notes of the times at which the floats passed certain points. Then I see, "12.50 a.m. Waterman's boat "made fast to float at Bottle Point, and kept his float "fast up to Fulham Dock." (*To the witness.*) You sent your report to Groves, and Groves sent it in to Messrs. Law and Chatterton?—Yes.

Cross-examined by Mr. Beaumont Morice.

14,475. Is this your writing?—No, that is Groves' writing.

14,476. (*Sir John Coode.*) Over what period did your observations extend altogether. You have told us of a fortnight previously to these dates; how long after this did you watch these boats; up to about what date?—Up to about the 20th of October.

14,477. Beginning in September, or when did you begin?—I do not think we began till the beginning of October.

14,478. Then it was for about a month?—We began, I think, a month after the others had begun.

14,479. For a month altogether?—Yes.

14,480. For the first fortnight you observed no irregularity, but upon this particular day you say you did?—Yes.

14,481. Did you observe anything irregular after that?—No, I did not.

Re-examined by Mr. Norman Bazalgette.

14,482. When you observed this about the float you made a report to Groves upon the subject within 12 hours after you had observed it?—Yes, I did.

14,483. And then Groves sent in his report at the end of the week?—I think on the following Saturday.

The witness withdrew.

Arthur James Avent called; examined by Mr. Norman Bazalgette.

*A. J. Avent.*

14,484. You are a Greenwich waterman, I believe?—I am.

14,485. Were you with Groves and Gadsdon upon the 30th October?—I was.

14,486. Did you see a float made fast to a boat?—Yes.

14,487. Upon what day was that?—The 30th October.

14,488. Who were the men that you were with?—Groves and Gadsdon.

14,489. Who were the men you saw?—Taylor and Clements. They were the men that were in the boat that was fast to the float.

Cross-examined by Mr. Lumley Smith.

14,490. You only speak to one occasion, I believe?—Yes, only to one occasion.

14,491. The two men in the boat were Taylor and Clements. What time of the day was it?—About a quarter past five in the morning. I was just come off duty.

14,492. Where were you?—I was rowing up just by Tripcock Point.

14,493. Was it light enough to see?—Yes, there was light enough to see.

14,494. Were the men asleep in the boat?—Yes, they were asleep. We went by and hailed them, but they made no answer, and we went back to the boat, and they jumped up from under a sail.

14,495. What number of float was it?—I do not think there was any number upon the float.

14,496. (*Sir John Coode.*) Did you make any remark to them about having caught them napping?—Yes.

14,497. What did they say?—They jumped up and said something. I do not remember the remark they made, but it was not a very nice one.

14,498. But the sun did not rise till 7 o'clock, and this was a quarter past 5?—Yes, it was.

14,499. Do you mean to say you saw this float actually tied on?—Yes.

14,500. Could you see it?—Yes, there was a line attached to the float.

14,501. You did see the line attached to the float?—Yes, I did.

14,502. And tied on to the boat?—Yes, to the boat's thwart.

14,503. Every one of you could see it?—Yes, every one of us.

14,504. Then what you could see all the rest of the men in the boat could see?—Yes.

The witness withdrew.

Adjourned to to-morrow at half-past 12 o'clock.

# THIRTY-EIGHTH DAY.

## Wednesday, 6th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, Esq., F.R.S., *Secretary*.

Dr. ANDREW WISE called in; examined by Mr. NORMAN BAZALGETTE.

*Dr. A. Wise.*
6 June 1883.

14,505. You live at 207, Burrage Road, Plumstead, and are a physician and surgeon?—I am.

14,506. Do you attend, and have you ever since the opening of the Crossness outfalls attended, the persons employed by the Metropolitan Board of Works who reside at Crossness?—I have.

14,507. What do you say as to their health compared to that of people who live in adjoining places?—It is quite as good as that of people residing elsewhere.

14,508. Have you been able to trace any diseases there to the influence of sewage?—Not any.

14,509. Have you found a larger proportion of diarrhœa or of zymotic disease prevalent there than elsewhere?—I have not.

14,510. Have there been any cases of typhoid fever since the outfalls were opened?—There has not been one case on the works to the best of my recollection.

14,511. How many men are employed there?—50 men are employed there, but the whole 50 do not reside there, some of the men are married and have children, and the population of the place itself is about 150.

14,512. That is including women and children, is it not?—Yes.

14,513. (*Chairman.*) Do you attend them for the Metropolitan Board of Works?—I do.

14,514. (*Mr. Norman Bazalgette.*) I presume the children include a certain number under five years of age?—Yes, they do.

14,515. As the result of your general practice at Plumstead, what do you say as to the prevalence of zymotic diseases there?—I do not think they prevail to any larger extent than in other places.

14,516. Can you tell me whether you have formed any general conclusions, as the result of your practice at Crossness and Plumstead as to the influence of the discharge of the sewage into the river upon the health of the neighbourhood?—I think it is nil.

14,517. Do you ever smell evil smells in Plumstead?—I do.

14,518. What do you attribute them to?—To the factories on the banks.

14,519. I believe some of the cottages you attend at Crossness are close to the banks of the river?—They are.

14,520. When you attend patients at those cottages have you ever been able to perceive any smell from the river itself?—At the houses themselves on the works there is no smell of sewage: that is to say, not in the houses.

Cross-examined by Mr. WEBSTER.

14,521. Where do you actually reside?—At Burrage Road, Plumstead.

14,522. Is this evidence of yours as to there being no greater amount of zymotic disease here than in other places based upon any tables or statistics which you have prepared?—Not any.

14,523. It is a general impression, is it not?—It is a general impression.

14,524. When you say zymotic disease is not more in this district than in others, what are you taking as the other districts with which you compare it?—I have had experience in other places.

14,525. Do you mean in other parts away from London?—In other parts of England.

14,526. Is this evidence based upon any number per 1,000 or anything of that kind?—No.

14,527. It is a general impression merely: it is not more than that?—It is a general impression.

14,528. Now about these which my learned friend Mr. Bazalgette calls "evil smells," what is it that you do smell there, do you know?—I am really not an expert in smells, but I should say it is an unpleasant smell: I cannot describe it; I do not think it is the smell of sewage.

14,529. Beyond saying they are evil smells, you cannot say that they are of any particular description?—No.

14,530. Do you trace any particular diseases to these smells?—No.

14,531. You have come and told us this generally, and I have no doubt you believe in it, but you have no statistics or tables of any kind with regard to any class of disease in your district or in any other district?—I am medical officer of the district, and I return to the board of guardians each year the figures, but I have not the figures here.

14,532. I ask you, have you any statistics to put before the Commission, or any facts as to the death rate or the disease rate either in your district or in the adjoining districts?—No, I have not.

14,533. (*Sir John Coode.*) Do you attend the people employed at both outfalls?—No, only at Crossness.

14,534. (*Mr. Webster.*) What is the area over which you consider that you have personal knowledge, where does it begin, and where does it go to?—It begins at Woolwich and goes to Belvedere from Shooter's Hill to the river bank.

14,535. How far down is Belvedere?—Belvedere is the adjoining parish to Plumstead.

14,536. Does it go below Crossness?—It stands rather above Crossness.

14,537. What is the highest point upon the river of your district?—It adjoins Crossness.

14,538. You said Woolwich just now, as I understood?—Woolwich is one of the boundaries.

14,539. What is the boundary lower down?—Erith.

14,540. Do I understand Erith is in your district?—It is not.

14,541. What parish is the most easterly parish there is in your district?—Belvedere.

14,542. Where is Belvedere with regard to Crossness?—It is above it.

*Dr. A. Wise.*
6 June 1883.

14,543. How much above it?—It stands upon the heights above.

14,544. (*Chairman.*) What do you mean by "above" it, in elevation or higher up the river?

(*Mr. Webster.*) In elevation?

(*Witness.*) It is in a direct line with it; it is not higher up the river.

14,545. (*Mr. Webster.*) Where is it with regard to Erith?—It stands above Abbey Wood.

14,546. Is Belvedere upon the river bank?—No, it is not; it stands back above Crossness.

14,547. How far back does it stand?—I should think a couple of miles.

14,548. Belvedere is a couple of miles back from Crossness, upon what we call the higher land, and then I want to know what is the nearest point upon the river banks to the outfall of which you have personal knowledge. Is there anything nearer than Woolwich?—No, none.

14,549. (*Chairman.*) I thought you said you attended the men at Crossness?—I did.

14,550. That is at the outfall itself?—Yes.

14,551. (*Mr. Webster.*) Your evidence relates to the people at the outfall?—Yes.

14,552. And not with regard to zymotic disease specially, but as to disease or illness generally?—Generally.

14,553. But your evidence with regard to zymotic disease and things of that kind is confined to the people at the outfall?—It is.

14,554. (*Chairman.*) I did not understand that you said it was confined to them, but that you said generally that you found an absence of zymotic disease there?—Yes, but it was given with regard to those people specially.

14,555. (*Colonel Ewart.*) How many people have you to attend to?—150 residing at the reservoir itself.

14,556. How far is that from where the sewage is actually discharged?—I should say less than a quarter of a mile; an eighth of a mile at the outside, I should say.

14,557. If you were called upon to recommend a site for additional labourers' cottages to be constructed, would you place them near the outfall or would you place them at some little distance off?—I should certainly not select the site of the outfall for fear of anything in the future occurring, but I do not think from past experience that there is any reason to expect it.

Re-examined by Mr. Norman Bazalgette.

14,558. Though you have no figures to lay before the Commission, do you think that your visits to the Crossness outfall have enabled you to form a pretty good opinion as to the presence or absence of zymotic disease there?—I think they have.

14,559. (*Chairman.*) You attend these establishments, I may say?—Yes, I do.

14,560. At the cost of the Metropolitan Board of Works?—Yes.

14,561. Why is it that they undertake the doctoring of their servants, do you know at all?—I should think from their being liable to accident.

14,562. Is that so; do they meet with accidents?—I have not had many cases of accident, but I may say also there have been months without my ever having been sent for to go down to see anybody at all.

14,563. (*Mr. Norman Bazalgette.*) As a matter of fact, I believe Belvedere is the adjoining parish to Erith?—Yes.

14,564. Is it upon high ground?—Yes.

14,565. (*Mr. Webster.*) But it is inland, is it not?—It is inland.

14,566. (*Sir John Coode.*) Did you say how long you had been in attendance upon the Board's officers?—Ever since the opening of the outfall; within a few months at any rate.

14,567. (*Dr. Stevenson.*) If there were any cases of ordinary illness amongst the children, would you be called upon to attend them in your official capacity?—No, I should not. I am simply appointed to attend the men, and not the children.

14,568. (*Chairman.*) I should like to ask you a question upon that. I suppose the children occasionally there are ill?—Yes, they are.

14,569. And I suppose the parents would in all probability employ you?—I have heard that in some cases they have had a doctor from Erith, but, as a rule, I have attended them.

14,570. (*Dr. Stevenson.*) Supposing cases of ordinary illness did occur among the people there, and that you were not called in, such cases as typhoid or diarrhœa or diphtheria, do you think you would hear of those cases?—I am sure I should, the superintendent there would report them to me at once.

14,571. Are you frequently at the works?—I have gone several months without going down there, owing to the absence of illness.

The witness withdrew.

(*Chairman to Mr. Bazalgette.*) Sir John Coode told me yesterday a thing I did not know, which was that the Crossness sewage did not fall into the river at all, but is conducted under the water of the river and finds its way through the bottom.

(*Mr. Law.*) That is so; it issues below low-water mark.

(*Chairman.*) So that it always has a covering of water over it when it comes out?

(*Mr. Law.*) It is never discharged visibly.

(*Sir John Coode to Mr. Law.*) About what depth of water is there over the pipes at low spring tides?

(*Mr. Law.*) At low spring tides I should say the opening was just covered, but we will give you the exact dimensions.

(*Sir John Coode.*) How does the water manage to get out?

(*Mr. Law.*) By the increased head from the pressure of the sewage in the reservoirs.

(*Sir John Coode.*) But it does not get covered with gravel or anything of that kind?

(*Mr. Law.*) No.

(*Sir John Coode.*) There is strength enough to wash that away.

(*Mr. Law.*) Yes; and, the bed of the river being deeper below it, it is never silted up.

(*Sir John Coode.*) About how much do the mouths of the pipes stand up above the bed of the river?

(*Mr. Law.*) I do not know, but we can give you a section which will show that.

(*Chairman.*) That is not the case at the Barking outfall, is it?

(*Mr. Law.*) No, you can see it at low water; the sewage outfall is covered at high water; you can see the sewage discharging there.

(*Chairman.*) Could not you have the same arrangement there as you have at Crossness?

(*Mr. Law.*) I do not know why it was not carried out there, but it has not been.

(*Chairman.*) It would be an improvement, I suppose, would it not?

(*Mr. Law.*) Scarcely, I think; it could be done.

(*Chairman.*) Surely it would be all the better, would it not?

(*Mr. Law.*) The beach there is very short, and when the reservoirs are enlarged I doubt whether the sewage will then be discharged after the water has fallen below the level of the outfalls.

(*Chairman.*) But you will not answer my question.

(*Mr. Law.*) Under those circumstances, it would not be an improvement.

(*Chairman.*) It would be neutral, neither better nor worse.

(*Mr. Law.*) Yes.

(*Sir John Coode.*) But, under present circumstances, do not you consider the mode of discharging at Crossness is preferable to that at Barking? 6 June 1883.

(*Mr. Law.*) Yes, under present circumstances.

Dr. JOHN DIXON called in; examined by Mr. NORMAN BAZALGETTE. *Dr. J. Dixon.*

14,572. You live at 133, Jamaica Road, Bermondsey?—I do.

14,573. And you are an M.D., L.R.C.P., London, and M.R.C.S., England, and L.S.A.?—Yes.

14,574. I believe you are also Medical Officer of Health for the Bermondsey District?—Yes, I am.

14,575. And you have been so for the last six or seven years?—Yes, for seven years.

14,576. Previously to that, what position did you hold?—I was poor law medical officer for 14 years.

14,577. (*Sir John Coode.*) Were you medical officer for the same district?—For the waterside district of Bermondsey; the parish was then divided into three districts, of which the one by the water side is by far the largest.

(*Chairman.*) What are we doing in Bermondsey?

(*Mr. Norman Bazalgette.*) It is a river side district, and I think it is one of the districts about which Dr. Corfield spoke; it also adjoins Rotherhithe.

(*Chairman.*) I thought we had agreed that Rotherhithe we need not trouble ourselves about. But, as Sir John Coode says, as you have brought the witness, you may take it shortly.

14,578. (*Sir John Coode to the witness.*) Over what length of river frontage would the district extend to which you have referred as having been medical officer for?—I was parochial surgeon for 14 years for the waterside district before I was medical officer of health for the whole parish.

14,579. You had a riverside district had you not?—Yes.

14,580. What extent was that?—391 acres. It was half a mile in frontage to the river, including the whole of the parish which adjoins the Thames.

14,581. (*Mr. Norman Bazalgette.*) I believe, as a matter of fact, your practice in Bermondsey has extended over a period of 25 years?—It has.

14,582. First of all, can you tell me whether in parts of the district near the river there is any evidence of any injurious effects on health from the sewage in the Thames?—None that I know of.

14,583. What is the character of the riverside population; is the density of the population as great there as in the districts further back?—It is rather more dense, if anything, because the houses are very old and they are smaller.

14,584. (*Sir John Coode.*) You are speaking of the district immediately on the river bank, are you not?—I should say this was so some years ago, because some of the houses have been pulled down and warehouses have been built; but I still say that the houses near the riverside are smaller and older.

14,585. (*Mr. Norman Bazalgette.*) And as regards the social position of the residents in those houses, are they the better-to-do classes or the poorer classes?—They are the poorer classes of the waterside neighbourhood; there are equally poor classes in the inland district.

14,586. Is typhoid fever in excess of the average, and is there any excess of zymotic disease?—Typhoid fever has been below the average for several years. In the last year we had only half the proportion of enteric fever which existed in London.

14,587. Is the proportion of children in this riverside district high as compared with the rate of population?—I cannot say for the particular district of the riverside, but for the whole parish we have more than our proper proportion of children, and that proportion is the largest in the St. James's district which includes the riverside. The effect of this is, that we have more than our fair proportion of deaths from measles and whooping cough, and in some years from scarlet fever and infantile diarrhœa; and our zymotic rate may be higher than that of London, although we have less fever.

14,588. Have you ever seen any signs of sewage at Bermondsey or smelt it?—No, I have not.

Cross-examined by Mr. WEBSTER.

14,589. The river frontage is almost entirely warehouses and graving docks and shipping, is it not?—It always has been, as far as the river frontage is concerned, but there are poor houses upon the opposite side of the Bermondsey wall within a few feet. All through Rotherhithe there are not private houses by the side of the river.

14,590. You have spoken of the average of enteric fever being half that of London; over what area is that?—Over the whole parish, the area of Bermondsey is 626 acres.

14,591. Just tell us roughly the boundaries; what is the southern boundary?—The Rotherhithe New Road.

14,592. Blue Anchor Road, does it go down there?—No, Blue Anchor Road is down the middle of it. The River Thames, West Lane, Southwark Park Road, Galley Wall Road, Rotherhithe New Road, Rolls Road, near Old Kent Road, Long Lane, Crosby Row, Snow's Fields, Artillery Street, and Dockhead are the boundaries.

14,593. Does that give me the main boundaries?—Yes.

14,594. That goes nearly two miles and a half from the river, does it not?—No, the parish is only one mile across.

14,595. And what length would you judge the average at, roughly?—A mile and a half, I should say, in length, and less than a mile in breadth.

14,596. This is the average over the 626 acres which you have given us?—Yes, we have only had nine cases of enteric fever in the 12 months.

14,597. Including all the part round Blue Anchor Road and Rotherhithe New Road and all that part?—Yes.

14,598. Have you any actual statistics from the river distinct?—I should like to know what you cal "the river distinct."

14,599. I would say the quarter of a square mile which is upon the margin of the river?—I can tell you this, that in no street near the river were there any cases of typhoid fever last year; those are the statistics with regard to the streets near the river.

14,600. My question is, have any statistics with regard to the strip next the river?—I have.

14,601. What are they?—There were only two cases of fever in the neighbourhood, and it was doubtful whether they were enteric fever or not, one being a child two years old, which was under the charge of a man who attends people for 6*d.* a time, and therefore not very likely to pay very much attention to the case; and the other was a child 12 years, also very doubtful; if that doubt were well founded, there was no case of enteric fever near the river last year.

14,602. Is Saint Olave's, Southwark, in Bermondsey?—Do you speak of the parish or union? Bermondsey parish is in Saint Olave's Union, and Saint Olave's parish forms a part of that union.

14,603. What is the rate of zymotic disease per thousand for the Bermondsey parish?

(*Chairman to Mr. Webster.*) Is it material to you to prove that, you can find it out yourself?

(*Mr. Webster.*) We have it in the evidence.

*Dr. J. Dixon.*
6 June 1883.

(*Chairman.*) That is a speculative and fishing question, is it not?

(*Mr. Webster.*) No my Lord, we have it in already, but this gentlemen says it is something different.

(*Chairman.*) You had better put the question directly.

14,604. (*Mr. Webster to the witness.*) In St. Olave's is not the death rate 4·46 per 1,000 for the 10 years from 1871 to 1880?—Are you speaking of the parish of St. Olave's, or the district, or the union?

14,605. I am speaking of the registration district?—There is no registration district, there is a union which includes several districts.

14,606. The table put in yesterday by Dr. Tripe includes St. Olave's, St. John, Horselydown, and St. James, Bermondsey, and it gives 4·46 for the average of the 10 years?—That is the union, not the parish.

14,607. Do you suggest that that is less than the average of London?—I have not suggested so.

14,608. London is 3·84 and this is 4·46; now I should like to ask you what is the rate you have got for this particular parish?—For what year?

14,609. For the average of the 10 years from zymotic disease?—4·6. This, of course, includes all kinds of zymotic disease. Last year our zymotic rate was 4·80, while the London rate was 3·49. Our rate for whooping cough was 2·03, that of London being 1·20. Our rate for measles was 1·24, that of London being 0·60. Our excess from these diseases alone exceeded our excess above the general zymotic rate for London.

14,610. Then I do not understand your statement that it is only half the average of London?—I was speaking of enteric fever, not of zymotic diseases all together.

14,611. What have you got down for fevers?—They are not separated for the 10 years, but I can give it you for the last year for fever. 1882.—Enteric fever per 1,000 population.—London, 0·25. Bermondsey, 0·10.

14,612. I asked you for it for the 10 years and you have not got it?—The tables includes the totals of all zymotic diseases.

Re-examined by Mr. Norman Bazalgette.

14,613. Bermondsey you tell us has an area of 626 acres?—It has.

14,614. It is so arranged as to present a considerable frontage to the river?—It is.

14,615. (*Dr. de Chaumont.*) Have you observed any difference in the state of health in your district in the last 10 years; is it more or less healthy than when you began your practice?—The state of health has considerably improved.

14,616. (*Sir John Coode.*) Do you attribute that improvement to any particular cause?—I attribute it to the main drainage in a very large measure, and to the filling up of the tidal ditches which formerly existed, and also to improvements in the dwellings of the poor.

The witness withdrew.

Surgeon-Major Charles William Griffith called; examined by Mr. Norman Bazalgette.

*Surg.-Major C. W. Griffith.*

14,617. You are a member of the Royal College of Surgeons of London, and a licentiate of the Royal College of Physicians of London?—Yes.

14,618. And you are also Brigade-Surgeon in charge of the Magazine at Purfleet, below the outfalls?—I am.

14,619. How long have you occupied that position?—Since November, 1880.

14,620. Do you live close to the river?—I live about 60 yards from the river.

14,621. Does your garden run down to the river?—It does.

14,622. How near is the hospital to the river?—It is about 35 yards.

14,623. What is the distance of the barracks and the residences of the various employés from the river?—The distance is about from 200 to 300 yards.

14,624. Speaking from the medical records which you have since 1876 of patients admitted to the hospital, can you tell us whether they contain any cases of disease which can be fairly attributed to the emanations from the river:—I do not think they do.

14,625. (*Chairman.*) Do you smell the sewage at all at Purfleet?—No, I do not.

14,626. Do you see it at all in the river, as it were?—The river is discoloured at times.

14,627. (*Sir John Coode.*) Do you experience any smell which you attribute to the factories?—Yes, there is a blood manure factory and a glue factory, one I believe is at Rainham, and the other I believe is on the other side of the river, upon the Erith side of the river.

14,628. (*Mr. Webster.*) Do you refer to Rainham in Kent?—No, to Rainham in Essex.

14,629. (*Sir John Coode.*) Do you mean that the smells of which you speak are never due to the river?—I have not perceived any.

14,630. Have you endeavoured to distinguish them as far as possible?—Yes, I should have done so if the river smell had been perceptible.

14,631. (*Mr. Norman Bazalgette.*) Are those smells that you smell from the factories equally prevalent whether the tide is flowing or ebbing?—It depends upon the wind, a north-west or west wind brings the smells which I originally attributed to the river.

14,632. (*Sir John Coode.*) What is the bearing of these factories from the magazine?—I should say west-north-west.

14,633. (*Mr. Norman Bazalgette.*) So that the wind you spoke of would convey the smells from the factories to the magazine?—Yes, I do not know where they are exactly.

(*Sir John Coode.*) I should have thought the factories were north-west to the magazine.

14,634. (*Mr. Norman Bazalgette.*) Referring once more to the record which you are speaking of, have you any case of typhoid fever upon record?—No, but one has recently occurred.

14,635. Is diarrhœa prevalent in the neighbourhood?—Not specially; rather the contrary, I should say.

14,636. What is the general health of the troops and the employés?—Very good.

14,637. Did I understand you to say that you have never smelt the river?—No I have not, except when the local drainage has been out of order.

14,638. And in hot weather, in summer, do you sit with your windows and doors open?—Yes, they are always open in summer weather.

14,639. (*Sir John Coode.*) All these factories would be to the west or north west from you, and therefore how a southerly would bring them does not clearly appear?—A west or north-west wind I referred to; Erith is west of Purfleet, and Rainham would be to the north of that again.

(*Sir John Coode.*) I can understand a westerly wind bringing the smell.

14,640. (*Mr. Norman Bazalgette.*) Is there much mud upon the Purfleet side of the river opposite the magazine?—No.

14,641. What is the shore there?—It is shingle and chalk stones, there is very little mud.

Cross-examined by Mr. WEBSTER.

14,642. Will you kindly tell me when you smelt these smells which you originally attributed to the river, and then attributed to the factories?—When I first went down there.

14,643. Could you give us that by the year?—It was about, I should say, early in 1881.

14,644. Have they continued since?—Yes, but they are worse since, because there is a new factory established at Rainham.

14,645. You smelt those smells early in 1881?—I did.

14,646. Now Rainham—is Rainham in Essex?—Yes, it is.

14,647. Do you know where the factories are to which you have attributed the smell?—I will tell you, as nearly as possible. The Rainham factory is situated close to the river bank opposite Rainham Station, as nearly as posible in a line with the Rainham Station.

14,648. That is to say, the Rainham station in Essex?—Yes.

14,649. Do you trace it to anything particularly; do you know the smell?—I know the smell well.

14,650. Do you know what it is the smell of?—Yes, I do.

14,651. What is it?—It is the smell either of a glue or a blood manure manufactory.

14,652. Now there is a factory at Erith, you say, where is that?—I do not know where the Erith one is situated.

14,653. (*Sir John Coode.*) Is there a factory at Erith?—Yes.

14,654. A south-west wind would bring that you?—Yes.

14,655. (*Mr. Webster.*) Would you say where you understand the factory at Erith to be, which you think you have smelt?—I do not know where it is.

14,656. You have been there since November, 1880?—I have.

14,657. That is a matter of something more than two years?—Yes, it is.

14,658. Do you know the "Cornwall" training ship off Purfleet?—Yes.

14,659. Where is that, above you?—It is below me, about 500 yards.

14,660. She is moored, if I remember rightly, upon the Essex shore?—Yes, on the Essex shore.

14,661. And a little below the outfall sewer?—Yes, it is about 350 yards from the outfall.

14,662. There has been a considerable outbreak of typhoid fever there, has there not?—It is always more or less prevalent there, I believe.

14,663. That has been the case with that ship and the boys there as long as you have known it, I understand?—There have been cases now and again, I believe, always.

14,664. And this last outbreak is a serious one, is it not?—It is not more so than others, as far as I have heard.

14,665. I am speaking of serious in itself, do you know the number attacked by it?—I do not know that.

(*Sir John Coode.*) Do you say there is an outbreak now?—Yes.*

14,666. (*Mr. Webster to the witness.*) Do you know that between 40 and 50 of the boys were attacked with typhoid fever during the last month?—No, I did not know that so many as that had been attacked. I know there have been some.

14,667. There have been several cases of typhoid fever, have there not, upon the shore at Purfleet during the last month?—There was one, that I know of.

14,668. Do you mean that you know there is only one, or that you only know of one?—I only know of one.

14,669. And scarlet fever?—Yes, there are several cases in the village now.

14,670. You were there in 1880; not in the summer of 1880, but in the summer of 1881 and 1882?—Yes.

14,671. You would agree, would you not, that from a temperature point of view and from a humidity point of view, 1881 and 1882 would be very favourable to the river in respect to not smelling, would they not?—I do not remember exactly whether they were hot summers or not.

14,672. You do not remember that either of them were hot summers?—No.

14,673. I suppose you would agree that if there is a considerable amount, or if there is more, what I will call fresh water in the river or land water, and the river is at a higher average, the river would not be so likely to smell?—It would not.

14,674. And if it did smell, it would not be so injurious to health?—I cannot answer that question.

14,675. What registration sub-district is your district in?—It is in the parish of West Thurrock. Purfleet and West Thurrock, I believe, it is called.

14,676. Do you know what Union it is in?—I could not tell you. I believe it is in the Orsett Union.

14,677. Do you know what registration district it is in?—I do not know that. I have nothing to do with that. I have nothing to do with the civil practice at all.

14,678. But you are the medical officer?—I am only medical officer for the barracks. I have nothing to do with the civil returns.

* The witness afterwards stated that his informant was wrong, there had been no case of typhoid, the cases called so were scarlet fever.

Cross-examined by Mr. BEAUMONT MORICE.

14,679. What kind of smell will you get from the factories at Erith?—It is difficult to describe the smell, but it is a very disagreeable one.

14,680. Being a medical man, can you tell us at all?—I think it is indescribable. I think having once smelt it you would remember it.

14,681. Do you know the village of Erith?—Not much, only from landing there occasionally.

14,682. (*Sir John Coode.*) Are you distinctly of opinion that the smell is not from the river?—I am quite certain as to what the smell is, I recognise it, distinctly.

14,683. (*Chairman.*) Do you ever smell it with an easterly wind?—No, I do not.

Re-examined by Mr. NORMAN BAZALGETTE.

14,684. Do you smell the smells from the factories chiefly in winter or summer?—I smell them chiefly in summer.

14,685. Now about the outbreaks of typhoid fever upon the "Cornwall," do you know anything about them, from your own knowledge?—I have occasionally visited the cases in consultation with Mr. Brett, the medical officer of the ship, and I have frequently seen cases for him in his absence.

14,686. At any rate, you have told us, that amongst the troops that are under your care, there has not been one case of typhoid fever?—There has not been one case since 1876, I think. But there is a case of typhoid fever at this moment in the quarters of one of the employés of the magazine, but he is a clerk in the employ of the London and Tilbury Railway, and was on a visit at home when he was attacked.

14,687. When he contracted the disease?—It is

*Surg.-Major C. W. Griffith.*

6 June 1883.

difficult to know when he was attacked, or when he contracted it, but he was at home when it broke out

14,688. (*Sir John Coode.*) How many men have you got at the magazine?—85 or 90.

14,689. All told?—Of the troops, but there are magazine employés in addition.

14,690. How many come under your charge?—Roughly speaking, men, women, and children, about 300.

14,691. You have been speaking of these 300 in the course of your evidence?—I have.

14,692. (*Mr. Norman Bazalgette.*) Referring once more to the outbreaks on board the "Cornwall," can you, as a doctor, attribute them to any special cause?—Do you mean whether I think they arose from the fact of the boys being on board the ship?

14,693. To what cause do you attribute the outbreak?—It is difficult to say—the boys there are continually being admitted—they are brought from the streets, and it is perfectly possible that a boy introduced may have the seeds of typhoid fever in him, and communicate them to others. I think one case, if I recollect rightly, was traced to that very cause.

14,694. (*Sir John Coode.*) Is the "Cornwall" the nearest ship to the outfalls?—It is the nearest training ship to the outfalls.

14,695. (*Chairman.*) I will ask you one question—do your men bathe at all?—They are not allowed to bathe in the river at all, because it is extremely dangerous, from the way in which the water runs into the bay, they do bathe there, but they are strictly prohibited from doing so, and, of course, they are punished if they are caught doing so, but, nevertheless, they do occasionally bathe there.

14,696. I do not know whether you are fond of bathing or swimming yourself, but is the water there such that you would not mind bathing in it yourself?—I do not think I should do that for several reasons. In the first place, the current is most desperately strong, and there are all sorts of currents, and, of course, the water is not so clean as you would wish it to be.

14,697. (*Dr. Stevenson.*) Referring again to the present outbreak on board the "Cornwall," you have been on board the ship, were you able to trace any case to importation by the boys?—I only went in consultation with the present medical officer.

14,698. (*Mr. Webster.*) Have you any knowledge of the present outbreak?—Yes, I have, but not as to the number of cases.

The witness withdrew.

Captain WILLIAM MILLER called; examined by Mr. NORMAN BAZALGETTE.

*Capt. W. Miller.*

14,699. You are captain of the "Castalia," and have been so ever since she was launched?—I have belonged to her since she has been launched.

14,700. For the last six and a half years where has she been stationed?—At Galleon's Reach and at Erith.

14,701. She has been stationed four years and a half at Erith, and for a year and eight months before she was at Galleon's Reach?—Yes, that is so.

14,702. Where is she stationed with regard to the tide?—She is stationed in the full strength of the ebb.

14,703. (*Chairman.*) Where is Galleon's Reach?—It is at the bottom of Woolwich Arsenal.

14,704. (*Mr. Norman Bazalgette.*) From on board the "Castalia," can you on the ebb see any traces of sewage in the river?—You cannot see any traces of sewage.

14,705. What can you see?—You can see refuse of all kinds floating there.

14,706. What kinds of refuse?—You see such things as grease floating down, and cabbage leaves, and things of that sort.

14,707. Do you see any excrementitious matter?—No.

14,708. (*Chairman.*) Is the paper which is used in the closets all mashed up by that time?—Yes, it is; you cannot see it.

(*Mr. Norman Bazalgette.*) Do you remember the hot summer of 1881?

(*Mr. Webster.*) You call it a hot summer, but I do not think that the statistics show that it was so.

(*Witness.*) I do.

14,709. (*Mr. Norman Bazalgette.*) Did you observe any smell from the river then?—There was a slight smell, not much.

14,710. At what period of the tide was this?—It was about the first shoot of the ebb.

14,711. Did you smell it during the year 1882?—I did not.

14,712. Taking the years 1881 and 1882, can you tell the Commission whether you have been in the habit of bathing in the river?—I have repeatedly in 1881 and 1882. I have always enjoyed myself in the river bathing; that is at the top of high water.

14,713. (*Chairman.*) That would be just before the outlet of the sewage, would it not?—I do not exactly know when they let out the sewage.

14,714. But that is so, I think, is it not?

(*Mr. Norman Bazalgette.*) I think that would be so.

(*Chairman.*) You are speaking of where you now are in Erith Reach.

(*Witness.*) The vessel is lying in Erith Reach at present.

14,715. And that is where you bathe?—Yes, inside of the vessel.

14,716. (*Sir John Coode.*) Did you bathe when the vessel was in Galleon's Reach?—I have bathed once or twice in Galleon's Reach, but not very often.

14,717. (*Chairman.*) Do I understand that you bathe in the open river?—Yes, there have been several gentlemen accompanied me bathing, and they always enjoyed themselves in the river.

14,718. (*Chairman.*) I do not see why not, the water is salt and clear at that time, is it not?—It is salt and clear at that time.

14,719. (*Mr. Norman Bazalgette.*) You have been on board the "Castalia" ever since she has been stationed there?—I have.

14,720. How many nights have you slept on board the ship?—I have slept on board, with the exception of about twelve nights altogether.

14,721. What kind of health have you enjoyed?—Excellent.

14,722. What crew does yours consist of?—Two men and a boy.

14,723. What sort of health do they enjoy?—They always enjoy excellent health.

14,724. Have you had any cases of illness on board?—None, but a boy was bad with rheumatic fever, and he was taken to the hospital in Erith and died.

14,725. Do you often smell bad smells where you are stationed?—Sometimes from the factories we do.

14,726. Do you trace those smells to any particular factory?—There is a glue factory. I do not think the smell comes much from the oil factories, but there is a glue factory where it comes from.

14,727. Which wind do you get them with?—A north-west wind; they are very bad indeed then.

14,728. Do you get those smells at any particular time of the year, or do you get them all the year round?—All the year round.

14,729. (*Sir John Coode.*) Do you get them from a south-east wind?—We cannot get them from a south-east wind.

14,730. But I want to know, do you get any smell from a south-east wind?—We get a smell from the brickworks with a south-west wind, but not from the factories.

14,731. It is a different smell altogether from what you get if the wind is north-west ?—Yes, that is so.

14,732. (*Mr. Norman Bazalgette.*) Is there a brickfield in the south-west ?—Yes, there is.

14,733. Has that a bad smell ?—It has, but it is nothing like the factory.

14,734. Have you had at times to shut your cabin door to try and keep the smells out ?—Yes, many a time.

Cross-examined by Mr. Webster.

14,735. You were in Galleon's Reach in 1881, am I right in that ?—No.

14,736. Not in 1881 ?—We came to Galleon's Reach upon the 22nd March 1877, and were removed to Erith on October the 4th, 1878.

14,737. And since October the 4th, 1878, you have been stationed at Erith ?—Yes; I have been stationed in the "Castalia" all the time.

14,738. What have you been doing there ?—I have been amusing myself partly.

14,739. The "Castalia" being laid up, do you remain there all day ?—Not all day. I go on shore occasionally, amusing myself; shooting sometimes.

14,740. I want to know this, have you bathed in Galleon's Reach ?—Yes, I have once or twice.

14,741. You were there for three or four years, why did you not bathe there more often ?—I beg your pardon, if you will look at the dates, seeing that I was there from 1877 to 1878, you will find I was not there for three or four years.

14,742. Did you bathe there ?—It did not suit me to bathe there perhaps.

14,743. But why did you not bathe in Galleon's Reach ?—Why did I not bathe this summer in Erith Reach ?

14,744. (*Chairman.*) Is it the fact that you did not bathe there because the water was not tempting; do you remember ?—Not at all; by no means; if I thought I wanted to have a swim, I should have gone in.

14,745. (*Mr. Webster.*) Do you suggest that the water in Galleon's Reach was inviting to bathe in ?—Yes, it was.

14,746. Was it just as inviting as in Erith Reach upon the top of the tide ?—No; scarcely.

14,747. Why not ?—Because there is not such a head of water comes up there upon the top of the tide.

14,748. Then the water is better in Erith Reach ? Yes; if you go round the river you will understand that.

14,749. Erith Reach is three or four miles further down than Galleon's Reach, is it not ?—Yes it is.

14,750. Now you say you remember the hot weather of 1881; how much of it was there ?—I cannot say.

14,751. Was there a week ?—I think there was more than a week.

14,752. About what month was it ?—It was June and July, I think.

14,753. The river began to smell faintly, as you have said ?—Yes, it did.

14,754. About how long after the hot weather began did the river begin to smell faintly ?—It was smelling when the hot weather was on.

14,755. What was it smelling of ?—That I cannot say.

14,756. Can you describe the smell ?—There are so many smells, I cannot pick them out.

14,757. Did you mean a smell from the water when you said the river began to smell faintly ?—Yes.

14,758. Had you ever smelt it before ?—No, I had not.

14,759. And you have never smelt it since ?—I have not.

14,760. Was there any smell in 1882 ?—No; there was no smell in 1882.

14,761. (*Chairman.*) Did it smell at all times of the tide ?—No, it smelt about the first shoot of the ebb.

14,762. That was just after your bath then ?—Yes, after my bath.

14,763 (*Mr. Webster.*) What I want to put to you is this: you do bathe when you have the fullest amount of water up ?—Yes.

14,764. Did you not know that the sewage was let out upon the beginning of the ebb ?—I did not know whether the sewage was let out upon the beginning of the ebb, or not.

(*Chairman to Mr. Webster.*) Can you not trust the Commission for this ? Captain Miller says, and with perfect truth, that just at the turn of the tide he bathes.

14,765. (*To the witness.*) I suppose you could not comfortably bathe when the tide is running strong, could you ?—I could not.

(*Chairman.*) Then the witness says that shortly after that he smells a strong smell, and we know that is about the time the sewage is let out; cannot you trust to us to know that that is the time that the sewage comes out ?

14,766. (*Mr. Webster to the witness.*) I understood you to say that you did not know exactly the time; you knew the sewage was turned out shortly after high water, or about high water ?—It is turned out about high water, or shortly after high water.

Examined by the Commission.

14,767. (*Sir John Coode.*) Do you perceive any sign in the colour of the water of the sewage being let out. Do you think you could tell, standing on board the ship, when that sewage is coming near the ship ?—I could not. I have watched for the sewage coming down most minutely, and have never noticed any sewage in the river whatever.

14,768. Have you watched it with the object of detecting it ?—Yes, I have, because there was so much said about it in Erith.

14,769. You have often watched it with that view ? —Yes, I have, and I have never been able to detect it.

14,770. About what time was it when you expected to see the sewage coming from the outfall ?—About three-quarters of an hour after the ebb came down.

14,771. (*Chairman.*) Why was the "Castalia" removed from Galleon's Reach ?—Because after the loss of the "Princess Alice," when she was lying there, it was said that we blinded the reach, that vessels could not see their way up the reach.

14,772. (*Sir John Coode.*) You mean that, the reach being narrow, the two boats combined obstructed the view; that was the reason ?—Yes.

The witness withdrew.

*Mr. E. Doggett.*

6 June 1883.

Mr. EDGAR DOGGETT called in; examined by Mr. NORMAN BAZALGETTE.

14,773. Are you an assistant accountant in the office of the Metropolitan Board of Works?—I am.

14,774. I believe you have been in the Metropolitan Board of Works for 20 years?—Yes, I have.

14,775. And for two years previously you were in the Census Office?—I was.

14,776. And during that time you had frequent experience in collecting and arranging statistics?—I had.

14,777. Did you assist Dr. Tripe in getting the tables and figures which he put in yesterday at Somerset House?—I did.

14,778. Will you state in what way you assisted him?—I attended several conferences with Dr. Tripe and the solicitor to the Board of Works, and talked over the information that was required, that is to say, the matter of the selection of the sites that would be affected by the sewage, if any sites were affected.

(*Chairman to Mr. Norman Bazalgette.*) Where is the "Cornwall"; is it above or below the outfall?

(*Mr. Norman Bazalgette.*) It is below; it is just opposite the word "Purfleet"; it is a mile or two miles below the "Castalia."

(*Mr. Webster.*) I am told it is about a mile.

14,779. (*Mr. Norman Bazalgette to the witness.*) Will you tell us what steps you took to assist Dr. Tripe in his investigation?—I attended at certain conferences at which the question of selecting the areas which would be injuriously affected by the smell of the sewage was gone into. Those areas were pointed out on the map, and I then visited the areas (Greenhithe excepted, as the registrar had put no addresses against the deaths there) with a view to ascertain by personal inspection the names of the streets and parts of streets, and the street numbers of houses that were within those areas. I then went to Somerset House, and had access to the books of the Registrar-General, and, having made out a list of the streets and parts of the streets within the various areas, I obtained a copy of the Registrar's books of deaths and took out the whole of the deaths that happened within those various areas.

(*Chairman.*) What is the object of this gentleman's evidence? He actually ascertained the statistics upon which Dr. Tripe reasoned. Is that the effect of it?

(*Mr. Norman Bazalgette.*) That is one point of it, but another is that he has visited the localities himself, and he will tell us something about the density of the population.

(*Witness.*) Having made out a list of all the deaths that occurred within those various areas, I sent copies of those lists to Dr. Tripe.

14,780. I believe you also went over the Registrar-General's register of deaths, and obtained a list of deaths occurring on board the training ships and in the infirmary at Greenwich?—I did.

14,781. And that information you also sent to Dr. Tripe?—I did. I also obtained the occupations of some persons who died within the various areas, where it was thought necessary by Dr. Tripe.

14,782. And you went to the office of the Metropolitan Asylums District Managers, and obtained the report of the various hospitals under their control?—Yes, and from them I tabulated the deaths from all diseases, except smallpox, under the head of typhus, scarlet fever, enteric fever, and other diseases.

14,783. The Commission have before them Dr. Tripe's spot maps that he brought yesterday. I believe you have been over the Erith district which is shown upon the spot map?—Yes, I have.

14,784. You walked over it with the map in your hand?—Yes, I did.

14,785. Can you tell us whether the ordnance survey is corrected up to the present?—It is not. At least my copy was not, and I was told that my copy was the latest printed.

14,786. In what respect is it incorrect?—Many rows of houses and streets are not marked upon the ordnance surveys.

14,787. I believe you produce a map which shows the ordnance map of Erith up to date?—To a certain extent it is corrected, but I am not a surveyor, and of course it is only roughly done. It was done for my own purposes.

(*Sir John Coode.*) It is corrected in what respect—as regards new buildings or additional buildings?—Yes.

14,788. (*Mr. Norman Bazalgette.*) My next question covers that. (*To the witness.*) Will you point out in what respect it differs from the published ordnance map?—There are a great many streets and rows of houses which are in existence now, and have been for many years, which are not down upon this map,—this map, the ordnance survey, having been made many years ago.

14,789. (*Sir John Coode.*) At what date, do you know, was that map published? You will find it at the bottom of the sheet?—This was surveyed in 1865. I was told at the time that this was the last published map; so that anybody looking at the map of Erith would say that there are a great many open spaces in such and such divisions which really do not exist, as they are now covered with houses more or less.

14,790. Is this evidence with reference to the questions that were asked of Dr. Tripe yesterday with regard to the open spaces?—Yes.

14,791. (*Mr. Norman Bazalgette*) Speaking generally, should you say that any part of Erith can be said to be densely populated?—No, no part of Erith can be considered to be densely populated.

14,792. Where are the houses closest?—The houses are closest in the small district, that would be at the angle of High Street, starting from the "Yacht," and going in an easterly direction up High Street, and then turning in a southerly direction as far as Colebrook Street. From Colebrook Street to the river they run one way, and then in an opposite direction from Colebrook Street, crossing the High Street, across to a point near the police station; and from there again to the "Yacht." That would comprise the district which is most closely populated. The "Yacht" is a public-house near a public-house called the "Crown," where a double dotted line runs out to low-water mark, on the map.

14,793. (*Mr. Norman Bazalgette.*) Then there is another densely populated part at the lower end of the Bexley Road, is there not?—The little district I have spoken about would include the lower end of the Bexley Road.

14,794. That part, as the map shows, is all adjacent to the river?—That part is all adjacent to the river.

(*Chairman.*) Is this evidence for the purpose of accounting for an apparently larger number of spots upon Dr. Tripe's plans?

(*Mr. Norman Bazalgette.*) No. It is to show that the district which Dr. Tripe said was singularly free from spots is, as a matter of fact, densely populated.

(*Chairman.*) It is not to explain away an apparently bad case, but to make an absolutely good one.

(*Mr. Norman Bazalgette.*) It is merely to show the density of the population.

14,795. (*To the witness.*) Now will you do the same thing with regard to Woolwich; will you just show where the most densely populated parts of Woolwich are. I believe you have been over the Woolwich area to determine this question more than once?—I have been over the Woolwich area twice, and the parts I am about to speak of I have gone all through.

14,796. Which is the most densely populated part?—The part of Woolwich which is bounded on the north by Rodney Street and upon the west by Globe Lane; it is bounded on the south by High Street, and on the east by Harden's Lane.

14,797. I daresay you can give me the dimensions of the plot which is enclosed by those boundaries?—I have measured it out by the ordnance survey, and I find it is 460 feet upon the south side and about

500 on the north, and the mean depth is about 200 feet.

14,798. That gives an area, I believe, of about 96,000 square feet?—Yes, about 96,000 square feet.

14,799. How many houses are marked upon the ordnance survey plan?—96, and there is a rather large space in Nelson Street occupied by a lecture hall.

(*Chairman to Mr. Norman Bazalgette.*) Is this hopeful? Could not you ask this gentleman in a general way whether it is not a fact that these districts are densely populated; how can we carry in our mind that there are 96 houses in any particular place?

14,800. (*Mr. Norman Bazalgette.*) If your Lordship will remember, when I was asking the witness about Erith, he said that no part of Erith could be said to be densely populated, but that the houses were closest in the riverside area. (*To the witness.*) Taking Dr. Tripe's map which was put in yesterday, could you say that the houses are closest upon the margin of the river?—Yes, they are.

14,801. Does the same thing apply to the Greenwich spot map?—Yes; the most densely populated part of the area for Greenwich is the part near the river.

14,802. I believe you have been also over the Rotherhithe district?—I have.

(*Chairman.*) Have we got to Rotherhithe again?

(*Mr. Norman Bazalgette.*) I thought you took Rotherhithe as a boundary inclusive.

(*Sir John Coode.*) We heard a good deal about Rotherhithe.

(*Chairman.*) It might be a remarkable thing as showing that the river did not poison people there; but, as you have no sewage discharged up there, I do not see what is the use of it.

14,803. (*Mr. Norman Bazalgette.*) A witness was called on the part of the Corporation who gave very elaborate evidence to show that Rotherhithe was made unhealthy on account of the river passing through it. I refer to Dr. Browning. (*To the witness.*) I will put it generally. Taking Dr. Tripe's spot map, is the district nearer to the river in Rotherhithe densely populated, or more densely populated, compared to the rest of the district?—The most densely populated part of that district is the part nearer to the river.

14,804. I gather from your answer that you do not mean immediately abutting on the river?—No, the whole of the immediate frontage to the river in Rotherhithe is occupied by wharves and public-houses, upon the other side of the street the houses are very close together indeed, especially at the western part of the area upon the map.

Cross-examined by Mr. Webster.

14,805. This plan which you have put in of Erith even now shows a considerable number of open spaces, does it not?—Yes.

14,806. You do not mean to describe Erith as a densely populated place?—I stated that it was not a densely populated place.

14,807. And with regard to the other plans to which you have referred, do you say, taking the last one, namely, Rotherhithe, that Adam Street and Albion Street are not as densely populated on the average as any other area of equal size?—I think not, because you will find that between Albion Street and Adam Street all the houses have little back gardens which are equal in size or larger than the houses themselves, and besides that there is a good broad street all round.

14,808. Now, with regard to Woolwich, I want to ask you this question. As it stands now, is not the population substantially equally distributed over the whole of the map?—No, I do not think it is.

14,809. Which do you say is the most densely populated?—In the small area which is chosen by me as being the most densely populated; I think you will find that the houses are more close there than in any other part of the area taken.

The witness withdrew.

Dr. Francis Mead Corner called; examined by Mr. Norman Bazalgette.

14,810. You are a Member of the Royal College of Surgeons of England, and a Licentiate of the Apothecaries' Society?—I am.

14,811. You are and have been, I believe, for some time past Medical Officer of Health to the south district of Poplar?—I have.

14,812. For what period have you occupied that office?—I have occupied that office since September 1877.

14,813. Does the south district comprise those portions of the district which front upon the river?—It does. I have a skeleton map here which gives the boundary of the district to which I am medical officer, it extends from Blackwall to Limehouse, the river boundary being about 6 miles.

14,814. I believe, in addition to your being medical officer, you have had a private practice in Poplar for some 25 years past?—I have.

14,815. As a general practitioner amongst all classes?—Yes.

14,816. Do your patients include those employed upon the river, and in the docks and factories which adjoin the river?—Yes, they do.

14,817. Generally, has your experience in the district during the last 25 years induced the conclusion in your mind that the presence of sewage in the river has had any injurious effect upon the health of the district?—I have had no facts at all to suggest that.

14,818. Do you find that illnesses from typhoid, diphtheria, diarrhœa, and other zymotic diseases, are more present in the district immediately adjacent to the river than in those more remote from it?—No.

14,819. Are there a number of factories by the side of the river?—There are a great many.

14,820. Do they employ a large number of hands?—I may say many thousands.

14,821. Who all live in the district?—The great majority of them live near.

14,822. Do you find that the diseases you have named are prevalent amongst them?—No, I do not.

14,823. Do you have opportunities of comparing the health of your district with that of the north district of Poplar?—Yes; every month a return is made of all cases of death, and of cases of infectious disease arising both in my district and in that on the north, that is, Bow and Bromley.

14,824. That is for that part of the Poplar district furthest from the river?—Yes.

14,825. Do you also have an opportunity of comparing the class of diseases occurring in Poplar with that occurring in the Isle of Dogs?—Yes, I have. My district is divided into two arbitrary divisions, that is to say, the district over which I am medical officer, by the route cut across the Isle of Dogs by the East and West India Docks; they cut off the Isle of Dogs from the north of my district.

14,826. The Isle of Dogs is entirely surrounded by the river, is it not?—By the river and the docks.

(*Chairman.*) The docks were originally intended to be a canal to cut short the way round the island.

14,827. (*Mr. Norman Bazalgette.*) Do you know what the resident population of the Isle of Dogs is?—It is about 16,000.

14,828. (*Mr. Webster.*) Is that south of the West India Docks?—Yes, it is south of the West India Docks.

*Dr. F. M. Corner.*

6 June 1883.

14,829. (*Mr. Norman Bazalgette.*) Speaking of these districts, do you find that zymotic disease is, in proportion to the population, more prevalent in the riverine districts than in those further removed from the river?—I should say generally not, though in the last five years we have had an epidemic of scarlet fever in the Isle of Dogs, but to my mind it was not at all connected with the condition of the river; it was traceable to a particular school, and nearly all those attacked were children in that particular board school. I do not think it had anything to do with the condition of the river.

14,830. During the years 1857 and 1858 you were resident medical officer of the Seamen's Hospital "Dreadnought," were you not?—I was.

14,831. Where was she stationed?—She was stationed a little to the Metropolitan side of Greenwich.

14,832. And whom was she occupied by at that time?—They were sailors principally.

14,833. How many patients had you on board?—From 150 to 200, in addition to the officers.

14,834. (*Chairman.*) Did you attend them?—I lived on board.

14,835. (*Mr. Norman Bazalgette.*) Do you remember the summer of 1857, before the Metropolitan outfalls were opened?—I do.

14,836. Were there great complaints of the state of the river in that year?—There were.

14,837. Did the river, at the time when it was so much complained of, have an injurious effect upon the health of the people who lived upon the "Dreadnought"?—No, we could make out no ill effects whatever on board the "Dreadnought" either in the patients or in the attendants and officers living on board.

14,838. Did that strike you at the time as being a remarkable fact?—Yes, it did, very.

14,839. (*Chairman.*) Even then it did not affect you?—Even then, we had no evidence of evil effects in the patients or officers; we had none of the effects that you would have expected.

14,840. (*Colonel Ewart.*) Was the water foul in smell?—Yes, it was unpleasant to the smell; that is to say, in rowing to and fro, you got a very unpleasant smell.

14,841. (*Mr. Norman Bazalgette.*) Did you receive a good many cases of typhoid fever, and treat them there?—Yes, we had a considerable number.

14,842. Did you find in any case of typhoid fever that came on board that the disease was communicated to others?—No, it was not; we had a considerable number of cases of typhoid fever, sometimes over a dozen, on the medical deck to which I was attached at one time; but, with one exception, during the two years I was there it did not spread to another patient.

14,843. Dr. Letheby at that period was the medical officer of health for the City of London?—He was.

14,844. Did you, at his request, report these various facts to him?—Yes, I did.

14,845. (*Mr. Webster.*) Is the report in writing?—Yes, it was a private communication. What use Dr. Letheby made of it, I do not know.

14,846. (*Mr. Norman Bazalgette.*) I may take it that, as the result of your experience at Poplar, the Metropolitan outfalls have not had an injurious effect upon the health of the inhabitants at Poplar?—Certainly not. I have no evidence of it.

14,847. (*Chairman.*) Do you yourself see any sewage at Poplar?—No, I cannot say that I do. In certain portions of the bends of the river where the tide gets in, you do get a certain amount of mud, but I have had no complaints of bad smells from those who live there; and I have been in houses overlooking the river, and I have never had occasion to notice any smells.

14,848. I suppose it would be worst at Blackwall?—It is worst at Blackwall, where the Trinity Corporation has its premises.

14,849. (*Mr. Webster.*) That is at the corner of Bow Creek?—Yes, where the River Lea has its entrance; but the wash of the steamers going up and down seems to cleanse the banks of the river to a great extent where we are.

Cross-examined by Mr. Webster.

14,850. Have you smelt it at Blackwall and Bow Creek yourself?—No, I cannot say that I have ever noticed anything objectionable from the banks of the river, or the river itself.

14,851. Neither at Blackwall or at Bow Creek?—No.

14,852. Is it your view that the condition of the river in London, in 1857 and 1858, was not injurious to health?—There is no such evidence, either from my experience or the experience of others with whom I have had the opportunity of talking. For instance, taking Dr. M'William, who was surgeon to the Customs, his experience was that the Custom House officers, who worked on the Thames did not suffer unduly.

14,853. But I want an answer to the question. Is it your opinion that the condition of the Thames in 1857 and 1858, in London, was not injurious to health; it is not a question of whether it is evident or not, but as a medical man, is it your opinion that it was injurious to health?—I should expect that it would be.

14,854. Are you aware that the death rate in London did sensibly diminish after the sewage being taken to Barking and Crossness?—Yes.

14,855. Do you not attribute that to a great extent to the sewage being taken out of the water between Chelsea and London Bridge?—I should be more disposed to attribute it to the sewage system than to removing it from the water in the Thames near London. I think it was the system.

14,856. I do not understand you?—The sewerage system has removed the sewage more rapidly from the homes of the people than before. There were a great many cesspools existing before.

(*Chairman to Mr. Webster.*) You would hardly suggest that the people at Highgate suffered from the sewage being in the Thames in 1857, would you.

(*Mr. Webster.*) I am not saying so at all.

(*Chairman.*) But the death-rate is diminished all over the metropolis.

(*Mr. Webster.*) I am referring to the evidence of previous witnesses to the effect that the condition of the river and the mud as it was in 1858 was distinctly injurious to health.

(*Chairman.*) Who said that?

(*Mr. Webster.*) Sir Joseph, then Mr. Bazalgette, and Mr. Hawksley.

(*Chairman.*) And the witness said he should have thought so.

(*Witness.*) I should have thought so undoubtedly.

14,857. (*Mr. Webster to the witness.*) You have given evidence to day that for some accidental reason or from extra precautions the bad condition of the river did not affect people upon the "Dreadnought." What I want to know is, is it your judgment as a medical man that the health of London was not improved by taking the sewage out of the river?—I believe it would be, at the same time I have no facts to support that.

Re-examined by Mr. Norman Bazalgette.

14,858. Under the system of sewerage which then prevailed, as you told us, there were a number of cesspools?—Yes.

14,859. And in addition to that all the sewers that discharged into the Thames were tide-locked?—Yes.

14,860. It is to the removal of that bad unsanitary state of things that you attribute the decrease of disease, rather than to the taking of the sewage out of the river in London?—Yes, I believe that is the more important of the two factors, the removal of the sewage quickly from the houses and the streets has been of more importance to health than diverting it from the river at London.

14,861. (*Chairman.*) But I understood you to say, you should have expected, taking this very case of the "Dreadnought," that it would have been a bad position for the vessel to be in, that it would have been better for the "Dreadnought" and the patients in it if the water that ran by it had been pure?—Yes.

14,862. But you could not trace any disease to the foul condition of the water?—I could not at that time.

14,683. I suppose one way in which it might affect health might be this, that if the smell was so offensive as to cause nausea that would be detrimental to health?—Yes, but it was found that when we got from 15 to 20 feet above the level of the Thames, nothing offensive was noticed. It was curious that after getting a certain distance up the stage ladder, nothing offensive was noticed, but at the surface of the water or a few feet above it, it was distinctly nasty.

14,864. (*Sir John Coode.*) That would be at the time when the air was quiescent, would it be the same when a breeze was blowing?—I should expect the offensive smell would be experienced. At a higher level when the air was still.

14,865. Then the condition of the offensiveness would be one depending on the state of the wind?—Yes. I presume the free dilution by the air of the gases given off would have something to do with it, either by dilution or destruction of the offensive gases.

14,866. You think there was a line of demarcation about 15 feet above the water level?—Yes.

14,867. Did you notice that more than once?—Yes, it was a matter of common observation among those on board.

14,868. Did you suggest it to anybody?—No. I think it was common observation.

14,869. You mean that it was so strongly marked, that it struck different people as a fact?—Yes.

The witness withdrew.

(*Chairman to Mr. Norman Bazalgette.*) May I take the opportunity of asking you what more witnesses you contemplate calling?

(*Mr. Norman Bazalgette.*) We shall have, I should say, three or four chemical witnesses.

(*Chairman.*) Could not you examine them *en bloc* and call them in together?

(*Mr. Norman Bazalgette.*) Though we shall probably have to examine the principal chemical witnesses at length, we can take the others comparatively shortly.

(*Chairman.*) You might have the others in the room, and then after you have examined your principal witness, you might say to them, "Do you agree "with that evidence, or do you desire to add to or "qualify it in any way?"

(*Mr. Norman Bazalgette.*) To a certain extent we can do that, but scarcely to the whole extent.

(*Chairman.*) You will have three or four chemical witnesses?

(*Mr. Norman Bazalgette.*) Yes.

(*Chairman.*) And some microscopical witnesses, I presume.

(*Mr. Norman Bazalgette.*) Yes.

(*Chairman.*) And I think you have one more engineer to call, have you not?

(*Mr. Norman Bazalgette.*) I think there are two more, my Lord.

(*Chairman.*) Is that all?

(*Mr. Norman Bazalgette.*) I hardly like to take the responsibility of saying that that will be the case on behalf of the Metropolitan Board of Works.

(*Chairman.*) But as at present advised?

(*Mr. Norman Bazalgette.*) There may be a few more.

(*Chairman.*) It is all important for us to get through this matter upon this side of the holidays.

(*Mr. Norman Bazalgette.*) If your Lordship would say that above a certain point of the river you would consider that health was not affected, that would shorten the matter.

(*Chairman.*) I should not like to give an interlocutory decision of that sort.

*Mr. Norman Bazalgette* stated that, having no more witnesses to call to-day, he would proceed with the reading of the Erith agreed documents. (*The same was proceeded with. See Appendix A. J.*)

In the course of the reading, the following discussion occurred.

(*Chairman.*) If I understand rightly, Erith is shown to be a very healthy place; nobody says that any disease is traced to the sewage of the outfalls in the Thames, that is to say, no specific diseases.

(*Mr. Norman Bazalgette.*) That is so.

(*Chairman.*) You are showing that from other causes, Erith ought not to be a healthy place.

(*Mr. Norman Bazalgette.*) I think the object of the evidence rather is to show that what many witnesses have described as being the smell from the river, really was the smell of the factories.

(*Chairman.*) That might be your object, and is reasonable enough.

(*Mr. Lumley Smith.*) But the witnesses on both sides agree that the smells are distinct, that the smell of the river is quite distinct from the smell of the factories.

(*Chairman.*) What Mr. Bazalgette wants to show is, that there are such smells, and that is admitted, except that Mr. Webster asked whether there were any bad smelling manufactories at Erith.

(*Mr. Webster.*) That was to endeavour to get at the source of the smell the witness said he smelt at Erith, and his answer to me was that he did not know where it came from, so that I could not follow it up.

(*Mr. Lumley Smith.*) My learned friend has rather relied upon these documents as showing that the complaints are all of the factories and not of the river. Now there are several paragraphs which seem to show that at the time Dr. Jessett was of opinion that the river was in a very bad state. In the 5th paragraph of that Report, at page 7, he says, "I would again "draw attention to the fact that undoubtedly a large "quantity of sewage sent out from Crossness and "Barking is carried by the current on the river on to "our shores. Strenuous efforts should be made to "prevent this, but at present the outfalls are pro-"tected by the Public Health Act."

(*Mr. Norman Bazalgette.*) My learned friend relies upon these sort of passages, and I rely upon these passages in the Report taken in connexion with them to show the extreme healthiness of the district.

(*Mr. Lumley Smith.*) Dr. Jessett was asked for these reports by the Metropolitan Board of Works, and they have been produced at their request.

(*The reading was resumed.*)

(*Sir John Coode.*) That paragraph as to comparison in the Report of January 28th, 1881, has to my mind the effect of showing the desirability of carrying the comparison over a longer period, say seven, or eight, or ten years.

6 June 1883.

(*Mr. Norman Bazalgette.*) If you look at the date of the first report, you will see it begins practically in 1879, and winds up, I think, in 1882 or 1883.

(*Sir John Coode.*) Here is a comparison of the year 1880 with the year 1879, and the effect of the comparison upon my mind is to show the desirability of comparing a much longer period with another long period, because to compare one single year with another single year may easily be fallacious.

(*Mr. Norman Bazalgette.*) I am reading the paragraph to show what steps have been taken by the local authority to obviate the nuisance, but if I may anticipate by referring to a passage to show the state of things which exists at present, if you will turn to the end of the printed matter, that will show the state of things at present; it is at the bottom of page 19.

(*The reading was resumed and concluded.*)

Adjourned to Tuesday next at half-past 12 o'clock.

# THIRTY-NINTH DAY.

## Tuesday, 12th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.

FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.

WILLIAM POLE, Esq., F.R.S., *Secretary.*

Mr. HENRY LAW re-called; cross-examined by Mr. WEBSTER.

*Mr. H. Law.*

12 June 1883

14,870. (*Mr. Webster.*) I propose to take the few questions which I have to put in the order of the number to save your Lordship trouble in referring to them; but I must first refer to this. (*To the witness.*) I think you stated that you were acquainted with all the evidence given before the Commission?—Yes.

14,871. And you are of course acquainted with Sir Joseph Bazalgette's evidence?—Yes. I did not hear the whole of it, but I have a general acquaintance with it.

14,872. Did you hear it stated that the rain at Greenwich and Kew did not correspond?—I know he made that statement, but I did not hear it.

14,873. Were the tables from which Sir Joseph Bazalgette spoke prepared by you?—No, they were not.

14,874. Were they prepared under your superintendence?—No.

14,875. Or in your office?—No, they were not.

14,876. Have you considered the question of the rain corresponding at Kew and at Greenwich?—I have not looked into it recently, but I know from the former observations which were made by the Referees, and of course, I know it from general meteorological observations, that frequently when it rains at one place it does not at another, and especially that the heavier the rain the more partial.

(*Chairman to Mr. Webster.*) Would you mind telling me what is the discrepancy?

(*Mr. Webster.*) Sir Joseph Bazalgette said accidentally, because I am sure he would not misrepresent anything, that the rain at Kew and Greenwich did not correspond.

(*Chairman.*) Do you mean it did not correspond in point of volume, or quantity, or time?

14,877. (*Mr. Webster.*) That it did not rain upon the days at Kew when it rained at Greenwich; in fact, there was not a single day upon which it corresponded with the tables put in by Mr. Symons. (*To the witness.*) Now, I will ask you, have or have you not examined the tables, not speaking of general observation, but examined the tables with the view to form any opinion as to the coincidence of rain upon the same days at Greenwich and at Kew?—No, I have not examined the tables put in by Mr. Symons with that view

14,878. Or the tables put in by the Metropolitan Board of Works?—No.

14,879. Do you know that Mr. Symons' tables only showed the days upon which the rain exceeded 1 inch?—Yes, I do.

14,880. But I may take it that you have not gone into the question yourself?—No, I have not.

14,881. I will call your attention, if you please, to question No. 13,645, in which you refer to Mr. Baldwin Latham's general statement that the population of London and the sewage requirements of London have outgrown the drainage system; do I understand you as differing from that?—Yes.

14,882. You say it has not?—I do.

14,883. To what do you attribute the necessity for the large increase of storm outfalls being provided, say, during the last 10 years; do you know, one way or the other, that they have provided during the last 10 years a largely increased number of storm outfalls?—Yes; they are now at the present time providing increased storm overflows to take the rain from districts which, in consequence of new streets and roads being laid out, have had their rainfall brought into the sewers.

14,884. Will you forgive me if I ask you to answer the questions first, and then add anything by way of explanation. Now would you tell the Commission, as I understand you have the information, what number of storm overflows have been provided during the last 10 years?—I cannot do that.

14,885. (*Chairman.*) Can you tell the capacity?—I cannot do that.

14,886. (*Mr. Webster.*) Can you tell us the places at all where they are being made?—One is being made at Vauxhall Bridge, to relieve the Effra sewer, one is being made at Wapping, to relieve the Hackney Valley sewer, running out at London Wharf. Those two I happen to have been engaged upon, and, therefore, I know them.

14,887. Are there any others which you know?—I know there is another being made to relieve one of the tributaries of the Ravensbourne.

14,888. Where is that to come out; do you know?—I cannot give you the details of that.

14,889. But which side of the river is the Ravensbourne?—Upon the south side, at Deptford.

14,890. Has not there been a storm overflow provided coming down from Brixton and running into the Thames at Battersea?—I think that is the one I referred to as relieving the Effra.

14,891. When was that opened?—I cannot give you that. Sir Joseph Bazalgette will be able to tell you that better than I can.

14,892. And the Fleet Valley?—Yes, the Fleet has been relieved also.

14,893. How recently has that been done?—I cannot give you the exact date, but I think that would be about five years ago.

14,894. I would ask somebody on the part of the Board of Works to be good enough to put in a tabulated shape the storm overflows which have been provided in the last 10 years, with their capacity and place, and generally the districts which they are supposed to relieve?—No doubt that can be done.

14,895. Is there any occasion for the increased storm overflows in the old districts, except what I may call the increase of sewage?—It is the increase of rainfall, not the increase of sewage.

14,896. As between what periods?—Between the period when the sewers were constructed and the present time.

14,897. But I understand you to say, as your own engineering judgment upon it, that it is due to the increase of rainfall being different from what was contemplated?—I did not say that. I said the increase of rainfall, which is occasioned by the altered conditions of the present time, from what they were when the sewers were constructed.

14,898. You can easily get over me if you put it in those general words; but I ask you, do you say there is a larger rainfall now going on than that which was contemplated when the sewers were designed?—I do not say the rainfall itself is larger, but I say that in consequence of the increase in the surfaces which contribute the rain to the sewers, the rain which now comes down is larger in amount than that which was provided for.

14,899. (*Sir John Coode.*) I understand that a larger proportion of the rain which does fall has to be carried away through the sewers; is that what you mean?—Yes. For instance, in the Hackney district, formerly it either sunk into the ground or was taken off by the ditches or evaporated, but now that new districts are laid out and large surfaces are paved, the same result does not follow, but a larger proportion has to be carried away by the sewers.

14,900. (*Mr. Webster.*) You say it is partly due to the fact that more of the rain that falls is conducted into the sewers?—Yes.

14,901. That is from there being more paved surfaces and roads and houses?—Yes.

14,902. (*Chairman.*) Is not Sir Joseph Bazalgette the right person to ask this question, saying to him, you have given so much greater capacity of storm outfall, why did you do it. The witness is not the proper person to put it to. (*To the witness.*) I do not know whether you can give the answer?—I know it as a general fact.

14,903. But you do not know why it was done?—I do not know the details of the several cases, or the details of the necessities of the several cases.

(*Mr. Webster.*) Sir Joseph Bazalgette gave no evidence in chief which would have led me to cross-examine upon it, because Sir Joseph Bazalgette expressed no criticism upon Mr. Baldwin Latham's statement that in his judgment the present population of London had overgrown the drainage system.

(*Chairman.*) We can solve that difficulty by asking Sir Joseph Bazalgette to attend, and I will ask him the question, because you are asking Mr. Law for a speculative answer upon what may have been the motive, when you have a witness of unimpeachable integrity who can tell you what absolutely was the motive.

(*Mr. Webster.*) I have not the least wish to ask a single question which the Commission think unnecessary. I am quite willing to postpone any branch of the case; but finding in a statement of Mr. Law's that he differed from Mr, Baldwin Latham upon this point I felt justified in cross-examining Mr. Law as to his grounds.

(*Chairman.*) Did Mr. Baldwin Latham attribute these additional storm outfalls to the capacity for sewage not being adequate?

(*Mr. Webster.*) He never referred to it in that way.

(*Chairman.*) Then Mr. Law could never have differed from him in that way.

(*Mr. Webster.*) Your Lordship is taking one answer of Mr. Law's this morning, and taking it as Mr. Law's evidence in chief. Mr. Law's answer to me this morning is, "I do not agree with Mr. Baldwin Latham "that the population has outgrown the sewage "system." Now I ask him, if you do not agree with Mr. Baldwin Latham that the population has outgrown the sewage system, how do you account for the increase of storm outfalls.

(*Chairman.*) I think Mr. Law might tell you, "I do not know, and I do not care"; whereas that question could be answered in a moment by Sir Joseph Bazalgette.

*The Committee consulted together.*

(*Mr. Webster.*) I simply wished to intimate to the Commission that I did not accept and swallow whole a great many of the conclusions that Mr. Law has come to. I think I can show that Mr. Law has fallen into some errors. I do not in the least wish to follow up any of those errors beyond just indicating them.

(*Chairman.*) We think you ought to do so.

14,904. (*Mr. Webster to the witness.*) You say: True, there has been an increase of population, and that that has let more rain water into the sewers, and that has necessitated more storm outfalls; that is what you meant?—Yes.

14,905. That would, of course, bring with it an increased burden of sewage as well?—Yes, there would be an increase in the sewage.

14,906. Therefore, whenever the population goes on or houses go on increasing, leading to more rain being brought in, you have approximately a proportionate increase in the sewage as well?—Not necessarily; you cannot say that they bear the same proportion.

14,907. I do not say so. I said approximately proportionate?—It is a question how far the approximation might hold.

14,908. Would you now look at your diagram, No. 22; it is what you call the heavily-dotted district; will you tell me what is the district which you indicate as having that large increase of population in colour?—Even the colours do not show the increase of population.

14,909. Will you tell me which are the districts in which you say the large number of houses are growing up?—I have made no statement as to that.

14,910. You said just now that you attributed the necessity for storm outfalls to more rain being taken into the sewers from the houses which were being built?—No, I did not. I said it was the extension of paved roads, and so on, and the altered conditions of surface which have occasioned more rain coming down into the sewers.

14,911. Which is the district in which th increase is taking place?—The Hackney Valley is one, and the Valley of the Effra is another, and the Quaggy, which runs into the Ravensbourne, is another.

14,912. Does that plan show us which of the districts had sewers provided for a rainfall of an eighth of an inch in the day, and which for a quarter of an inch?—No.

14,913. Is there any plan which does, which I can compare with that?—I am not sure; it is in some of Sir Joseph Bazalgette's earlier reports, but I have not it with me.

14,914. I asked for the information in another shape, and I think it appears so upon the notes?—I am sure that Sir Joseph Bazalgette can give you the respective areas upon which he formerly took an eighth of an inch and a quarter of an inch.

14,915. Are you aware that the increase of population and building has taken place to a far larger extent

*Mr. H. Law.*

12 June 1883.

in the districts for which provision was made only for an eighth of an inch?—I do not think so.

14,916. Do you know one way or the other?—I think that a far larger increase of population has taken place in Battersea.

14,917. Any facts which you have, which you can speak to of your own knowledge as contravening what I put to you upon the north side of the river, I shall be glad to hear?—I cannot tell you the districts which have the larger provision upon the north side.

14,918. Will you tell me the districts which had that provision for an eighth of an inch?—I cannot.

14,919. Now will you turn to question 13,650. I observe that in that you give your total population at 2,596,054, in the table following that question; is that correct?—Yes.

14,920. Of course it has increased since 1881?—Yes; I gave the increase as 2 per cent.

14,921. For what population were the sewers designed?—I do not know.

14,922. I will put the figures to you?—But you must not take it from me whether they are right or wrong, because I have not the means of checking them.

14,923. But I will just put them to you, and you can correct me?—In Table No. 1 you have it divided; it is allotted there amongst the three sewers.

14,924. Now I will put it to you to see whether this is or is not accurate, that the contemplated population of the High Level sewer was 290,500, as against 256,329 which is what you have got for the High Level. For the Middle Level the contemplated population was 1,041,300 as against 1,209,081; and for the Lower Level 1,022,100 as against 1,130,644. Now assuming those figures to be correct, I will give you the results directly. Assuming that I am correct in suggesting to you that the population estimated for at the time of the sewage system for the northern district was 2,353,900, there would be an excess in the year 1881 upon the north side of upwards of 242,154 in 1881 only?—Yes, there is that difference between those figures.

14,925. Now, assuming, if you please, that the increase of population over the estimated or contemplated numbers did take place in the year 1881, do you still adhere to your answer that the drainage system is sufficient?—Yes, I adhere to it, and I have proved it by the figures I have put in to be amply sufficient.

14,926. Do I understand you to say distinctly that you had in your mind, when you prepared this diagram, the population contemplated by the original drainage system?—No, that formed no part of the inquiry. My inquiry was how far the drainage system was adequate to meet the wants of the existing population.

14,927. Then you have not considered what it was originally intended to meet. Now I will just take the south side, if you please. I wish to put the figures before the Commission. The High Level is 412,800 and the Low Level 681,800, and that makes 1,094,600 as against 1,284,048; those figures, you have said, you also did not have in your mind?—I would like to make one observation upon that. I do not know what you are reading those figures from; I do not know, for instance, the date of that report or estimate, and how far in the preparation of the matured plans deviations and alterations may have been made; because it is very possible that the allotments of the areas of the respective High, Middle, and Low Level sewers, which were originally contemplated, have been to a certain extent changed in the carrying out of the work; that must be borne in mind.

14,928. I am not dealing in the least with possibilities or probabilities, but I am asking this. Assuming those figures of population to have been estimated as having to be provided for by the sewers, as designed, your evidence is that the sewers were sufficient for a much larger population. Are you able to tell me if those figures are correct, in what the difference between the capacity of the sewers at one time and the other lies; is it in the different mode of calculation of the capacity of the sewers then from now, or what?—I should say certainly not; but you are asking me things quite out of my knowledge. But what I wish to say is this, that you have before you the whole of my calculations, the formula by means of which the discharging capacity of the sewer has been taken, is the one always used by engineers, and the only proposition I have put before the Commission is that the sewers are more than sufficient for the present population, that is quite independent from what may have been estimated for.

14,929. (*Chairman.*) There appears to have been an increase of population on the north side by 10 per cent.?—Yes, about 10 per cent.

14,930. I think Sir Joseph Bazalgette told us that he had provided for an increase of population, but he says the sewers will carry off double the amount of sewage that they now have to carry off when there is no rain; that is so, is it not?—They will carry much more than double.

(*Chairman to Mr. Webster.*) But I speak within compass; that is so, is it not?

(*Mr. Webster.*) I am following your Lordship.

(*Chairman.*) And that is true.

(*Mr. Webster.*) If it is true, a great many of my questions become unnecessary, but I think it is not true.

(*Chairman.*) Sir Joseph Bazalgette told the Commission, that he had had a piece of good fortune which he had not calculated upon. He calculated that the great bulk of the sewage would be running over the whole space at the same time, whereas he found that owing to the distance it had to travel, it did not come in that way. The question is, therefore, not what Sir Joseph Bazalgette calculated at the moment when he designed the sewers, but the question is what is their capacity now.

(*Mr. Webster.*) I respectfully submit that I do not accept Mr. Law's conclusions. I know your Lordship has put a question which has enabled Mr. Law to repeat what he believes to be true.

(*Chairman.*) I always give credit to counsel, and I should unquestionably do so to you, that they have some point to make when they persist after I have pointed out a difficulty. If you could show that the sewers are not anything like adequate to carry off the whole of the sewage when they are charged with rain, that would only show that the upper part of the river got more sewage into it than it ought to get; and upon that I should say that there is not a shadow of complaint about the upper part of the river.

(*Mr. Webster.*) With submission, that is not my point at all.

(*Chairman.*) Then you had better go on. I trust completely to counsel that they will not unnecessarily occupy time.

14,931. (*Mr. Webster.*) I am much obliged to your Lordship. I will not put a single question which is merely argumentative, and I will not put a question except for the purpose of indicating the view we take. (*To the witness.*) Now I notice at Question 13,652 that you have said you have adopted gaugings which were taken by Mr. John Taylor for the Referees to whom the Metropolitan Drainage Scheme was referred?—I did say so.

14,932. Do you allege that those gaugings are accurate?—I have every reason to believe that they are.

14,933. Do you say you have every reason to believe that they are?—Certainly.

14,934. Are you not aware that Sir Joseph Bazalgette, Mr. Bidder, and Mr. Hawksley, have repeatedly pointed out that the gaugings were wholly inaccurate?—I was not aware of that.

14,935. Did not you say that at the time you adopted them?—No.

14,936. Have you read the report of the 6th of April, 1858?—I have read it, but not very recently.

14,937. I will not trouble you to read it through now; are you not aware that Sir Joseph Bazalgette,

Mr. Hawksley, and Mr. Bidder, declined to work upon those gaugings?—No, I am not.

14,938. Are you not aware that Sir Joseph Bazalgette, then Mr. Bazalgette, refused to work upon those gaugings?—No, I am not aware of it.

14,939. You said "I have adopted the gaugings "which were taken by Mr. John Taylor for the "Referees to whom the Metropolitan Main Drainage "Scheme was referred by the First Commissioner of "Works previous to the construction of those "works; because those experiments extended over "some three or four months, and were taken with "very great exactness." Upon whose authority was this?

14,940. (*Chairman.*) What were these gaugings?—The plan for the Metropolitan drainage was referred under the Act to the Commissioner of Works who appointed a Commission, and that Commission deputed Mr. John Taylor to take elaborate gaugings of the metropolitan sewers for the purpose of determining the quantities which would have to be dealt with; but I would explain that I have made a very partial use of those gaugings. I have not used those gaugings to determine the quantity of the sewage, but only the rate of its distribution, the relative quantities coming down at different hours. The quantity has been determined upon the same basis that Mr. Baldwin Latham adopted, namely, the 5 cubic feet in 24 hours, and these gaugings were used simply to determine the rate of distribution.

14,941. (*Mr. Webster.*) I will read your own answer, "In order to determine the hours"?—Certainly, not the "quantity" but the "hours."

14,942. Will you kindly listen to me, "In order to "determine the hour at which the maximum flow "from each branch sewer will come down into the "intercepting sewer (by which I mean the Board's "sewer), I have adopted the gaugings which were "taken by Mr. John Taylor." My question to you is, do not you know that the accuracy of these gaugings was disavowed distinctly by Mr. Bazalgette?—No, I do not; but I should like to see the comments, because those comments would probably only refer to the mode of gauging and determining the quantity, and would probably not affect the relative quantities coming down at different times, that is the only purpose for which I used them.

14,943. I will refer you to page 48 of the Report of April 6th, 1858, on Metropolitan Drainage "Un-"questionably the most important results to be "obtained from gaugings is not that sought by the "Referees, but the determination of the amount of water "passing through the sewers as the produce of rainfall. "Dry weather gaugings for determining the amount of "ordinary sewage may be taken at any time, and on "only a few occasions, as they may be assumed to "afford, from a comparatively small number of "observations, a tolerably accurate result; the mode "in which the Government Referees took their "gaugings." Then the report describes the mode in which the Referees took their gaugings?—I have used only the dry weather gaugings.

14,944. "We have earnestly endeavoured to turn the "elaborate gaugings of the Referees to use for the "accomplishment of this end, and have expended "much time in efforts to reconcile discrepancies, to "eliminate errors, and to interpolate facts otherwise "derived, but we have not succeeded in this attempt "as we had desired. The Referees appear indeed to "have had objects in view altogether different from "those which we conceive to be most essential in an "inquiry of this kind. Having ascertained, to their "own satisfaction, the amount of the ordinary sewage, "they proceed to determine not the amount of rain-"flow which ought to be excluded from the river by "the sewers of interception, but the amount of "dilution necessary to render effective the only pos-"sible system of working the very peculiar outfall "channels." I will not read the rest of it, but I will ask you this, can you tell me any single report or inquiry since these gaugings in which they have been used by Sir Joseph Bazalgette or anybody else until you used them?—I really cannot; but what you have read there does not impugn the use that I made of them the least in the world, it impugns the use the Referees have made of them as regards the rainfall. I have simply used them for the purpose of determining the relative rates and not the quantities.

14,945. Can you give me the table of gaugings you have used?—It is Appendix 3, page 78, of the Report upon Metropolitan Main Drainage, 1857.

14,946. Will you just tell me how I shall know which gaugings you have used?—I have used the gaugings, as, in fact, it is stated at the head of Diagram No. 23, for the Northumberland Street sewer, the Essex Street sewer, and the Norfolk Street sewer.

14,947. Have you left out the Savoy Street sewer?—Yes, I have.

14,948. I put it to you thus—are you not aware that these are the very gaugings in which errors from 10 to 33 per cent. were pointed out by Sir Joseph Bazalgette at pages 51, 52, and 53. I have indicated enough for the Commission to follow what I mean?—My reply to that is exactly what it was before,—if I had made any use whatever of these gaugings to determine the quantities of rainfall mixed with sewage that were flowing, those errors would have applied; but I have simply used them for the purpose of determining the hourly rate at which the dry weather sewage comes down.

14,949. But that is the quantity flowing, is it not?—No, if you were to deduct the per-centages from those various amounts, it would remain identical.

14,950. But the hourly rate at which the sewage come down does give the quantity passing, does it not?—Not at all,—because one sewer may bring down double the quantity of the other, and they may both flow at the same relative rates; one sewer may discharge 100 times that of the other, and yet the rates be the same.

14,951. If you have given you the capacity of the sewer and the passage of the sewage, you know what is coming down?—Yes, of course, coming down you do; but I say I have used them simply for the purpose of determining the relative quantities, and not the absolute quantities.

14,952. Now, I will refer you to question 13,653. You say the maximum flow out of the Northern Outfall sewer is 15,000 cubic feet per minute, do you say that as a matter of fact?—I do.

14,953. Is it all pumped, or does part of it flow by gravitation?—The High and the Middle Level sewers flow by gravitation.

14,954. Then the answer is that the Low Level sewer is the only one that is pumped, and the others flow by gravitation?—Yes.

14,955. Do not they pump at Abbey Mills as much as 15,000 cubic feet a minute alone?—At the present time, do you mean?

14,956. I will ask you another question, what does your diagram No. 24 purport to show, because you have represented, as I understand your answer, that the maximum flow in the outfall sewer is 15,000 cubic feet a minute?—Yes, in dry weather without rain.

14,957. Of sewage?—Yes.

14,958. Now, I put it to you,—do you represent it as never exceeding that?—Of course not; when rain makes it larger, it exceeds it.

14,959. Then I do not understand what you mean by your answer to question 13,653, when you say, "The portion of the diagram coloured red shows at "each hour how much of that discharging capacity "would really be occupied in carrying away the "sewage at that particular hour; and therefore your "Lordship will see that the maximum flow in the "outfall sewer upon the northern side is at half-past "two, when it amounts to about 15,000 cubic feet." If you will tell me exactly what you mean by that, I shall be obliged?—I mean to say absolutely that that is the fact; and not only that, but that this is an over estimate by 50 per cent., because at the present

*Mr. H. Law.*

12 June 1883.

moment we have only two sewers working instead of three, and the height of the sewage in the two sewers is about what I take it at in the three at the present instant.

14,960. What I understand you to say is that the sewage alone will not exceed 15,000 cubic feet a minute?—Yes, that is purely an estimate, taking 5 cubic feet to an individual, and that the gaugings which I myself took the other day, being down there upon other business, showed that that was an over estimate.

14,961. Now, will you tell me what is the quantity by gravitation as compared with that which is pumped. I am told that 22 per cent. flows by gravitation to 78 per cent. pumped; if that is right, then I can pass on?—No, it is not that.

(*Sir John Coode.*) Is it not all pumped at Abbey Mills?

(*Mr. Webster.*) No, I understand the Middle and the High Level sewers run in by gravitation.

(*Witness.*) That is so; only the Low Level sewer, the 10 feet 3 sewer, is pumped.

14,962. (*Mr. Webster.*) I am told that Sir Joseph Bazalgette stated in the Mud Inquiry, that 22 per cent. of the sewage discharged at Barking goes by gravitation, and 78 per cent. is pumped?—But that would include the whole that there is, whereas I am only alluding to the dry weather flow.

14,963. But I am giving the percentage?—They simply pump the sewage out of the Low Level sewer.

14,964. (*Chairman.*) But the percentages must vary very much, because, as I understand, you said the High Level sewer had a vastly greater capacity compared to its work than the other sewers had?—Yes; the High Level is only filled to one-seventh while the Low Level is filled to one-half of its capacity. (*To Mr. Webster.*) I can answer your question; the High Level maximum flow is 1800 cubic feet a minute, the Middle Level maximum flow is 7,788 cubic feet per minute, and the Low Level maximum flow is 6,570 cubic feet, making together 15,070; they will not quite add up, because those are the respective maxima at different hours.

14,965. (*Mr. Webster.*) But my question was, what percentage of the actual discharge is pumped?—I will give it you; out of the 15,000 there is about 6,000 pumped.

14,966. That is got by adding the maxima quantities together?—Yes.

14,967. Now will you go to Question 13,658; you have added it up against yourself by 10,000 acres, it should be 65,000 acres instead of 75,000 acres; that is at question 13,658?—That is so.

14,968. Do you agree with the view expressed by Sir Joseph Bazalgette and others that there ought to be from each acre provision for a cubic foot and a half of sewage and rainfall?—I do not understand the question, it would depend upon the density of the population.

14,969. That there ought to be provision made, never mind whether it comes from one person or a thousand, for a cubic foot and a half per minute per acre of discharge?—But it must depend entirely upon where you put the acre; whether it is in the centre of a town or in the suburbs makes all the difference, you cannot lay down a general rule of that kind.

14,970. I only want to get you to answer the question?—You cannot make a general rule of that kind when you have a city more or less densely peopled in various parts.

14,971. But you do not agree, taking the 102 square miles and the 65,000 statute acres, that you can say what should be the quantity actually coming off per minute per acre?—That is the result of an arithmetical calculation, I cannot tell you whether or not the right proportion of sewage to an acre over the whole of London would come to $1\frac{1}{4}$ or $1\frac{1}{2}$ cubic feet.

14,972. I am not putting to you the sewage; I distinctly made it clear to you, if you followed me, sewage and rainfall yield in liquid per statute acre per minute; do you agree that a cubic foot and a half or a cubic foot is the right quantity to provide for?—Under what conditions; it depends entirely upon the conditions of the district you are dealing with.

14,973. The district of the Metropolitan area?—It may come out upon the average to that. I cannot say how that may be.

14,974. Have you, or not, formed any judgment as to what is the proper quantity as the governing principle?—I stated the principle I have taken here, viz., that of taking the whole of the rainfall as coming down where there are more than 80 persons to the acre, and then proportioning it to the number of persons to the acre.

14,975. Have you worked it out to the proportion per acre per minute in cubic feet?—No, I have not, and I do not know how it would work out.

14,976. Now I will refer you to your answer to question 13,661, you have taken the velocity at 180 feet per minute in the sewer?—No, that is not the velocity exactly through the sewer, it is the velocity of the rain in reaching the intercepting sewer, it may be through the sewer, or it may be through the gutters.

14,977. Would you enable me to check the formula through which you get at your 180 feet?—It is not determined by a formula at all.

14,978. How do you arrive at it?—It is purely as an estimate.

14,979. I presume, in arriving at the figure of 180 feet, you must have had some data to work upon?—Not at all.

14,980. (*Chairman.*) Then how did you arrive at the conclusion?—I know more or less what the velocity in the sewers generally is.

14,981. (*Mr. Webster.*) Then let us have it more or less?—180 feet per minute is rather a quick velocity; therefore I assumed what would be rather upon the safe side. So I took what was rather a high velocity, notwithstanding all the bends and turns of the sewer, and 180 feet per minute would be a good velocity in a well constructed sewer.

14,982. Then this is from some general opinion that you have that 180 feet is a high velocity?—Certainly.

14,983. Were the sewers actually gauged in 1865 as to the rapidity of the flow through them?—I am not aware of that.

14,984. Are you not aware that the sewers were actually gauged for velocity and quantity, and samples of the sewage taken from time to time and submitted to Professor Way?—No. I have been informed by Sir Joseph Bazalgette that he has made every search in the archives of the Metropolitan Board of Works, and that they know nothing whatever of these gaugings.

14,985. I will not make any concealment about it, because I am instructed that your figures are wrong, and here are the books (*producing some books of gaugings*). Have you had any actual gaugings of the rapidity or velocity of the flow in the sewers?—Not that I am aware of.

14,986. You have not worked upon any actual gaugings?—No, I have not.

14,987. Those books appear to have been inspected by your people in 1865?—I am informed by Sir Joseph Bazalgette that they never had a person in their employ of the name of Walker.

14,988. But I know nothing about a person named Walker. I have not said anything about it?—But these books are signed by a man named Walker. Mr. Baldwin Latham wrote to inform Sir Joseph Bazalgette that he had certain books of gaugings in his possession which were signed by a person of the name of Walker, and Sir Joseph Bazalgette caused every enquiry to be made at the Board of Works. No record of any such gaugings can be found, and they know no person of the name of Walker in authority in their employment.

(*Sir John Coode.*) What do you say those gaugings are?

(*Mr Webster.*) They are samples of sewage taken from time to time and sent to Professor Way for the purpose of making analyses, and those are not sent in by Mr. Baldwin Latham, but by Professor Way.

(*Witness.*) My belief is that those samples were taken by the Essex Reclamation Company, who were at the time engaged in promoting a Bill in Parliament. They were contemplating taking the sewage from these sewers down to Essex; but all I can say is that Sir Joseph Bazalgette has informed me that the Metropolitan Board of Works know nothing about them.

14,989. (*Mr. Webster.*) Your diagram in which these figures are used is only taken for 10 hours, why is that?—Because after that time the flow remains constant.

14,990. After what time does it remain constant?—Diagram 25 is to show the increase in the quantity of rain discharged from the sewers at successive periods in consequence of its not arriving from the distant parts so rapidly as from the nearest parts, but after 10 hours it runs as a constant quantity at the rate I have given here.

14,991. This calculation is based on the assumption that the whole of the sewers are adequate to carry off a quarter of an inch of rain in 24 hours, is it not?—No. This is to test whether they are or not. It is not assumed that they are; this is to test it.

14,992. I am afraid I have not followed you. Do you state that all the sewers are sufficient to carry off a quarter of an inch of rain?—I state that they are sufficient and much more than sufficient; that when they are carrying off that quantity with the maximum sewage they have a surplus capacity of 5,452 cubic feet per minute.

14,993. (*Chairman.*) And if they are not carrying it off, we have an overflow in the upper part of the river?—Yes, when the rain exceeds that surplus, then the sewers overflow.

14,994. (*Mr. Webster.*) What quantity is presumed to have fallen over London in this period?—A quarter of an inch over the whole of London.

14,995. Is that spread over the whole of the 24 hours?—Yes; I explained the effect of the vacant space which there was in the various sewers as compensating for sudden showers.

14,996. Now, if you please, will you go to question No. 13,678, where, in answer to Sir John Coode, and to question No. 13,679, where, in answer to Professor Williamson, you were calling attention to Dr. Frankland's evidence, and you said, "I may further call "your attention to this fact that I have gone a little "carefully into this matter of rain, because you have "also a report which Dr. Frankland put in, in which "Dr. Frankland assumes that of the whole quantity "of rain which falls upon the whole of London, in-"cluding the River Thames and the canals, however "slight the shower, four-fifths falls into the sewers, "and upon that very elaborate tables have been put "in to show the quantity of detritus which is brought "by the sewer;" and then Professor Williamson asked you this question, "Does Dr. Frankland say "that there is always that proportion, or that that is "the average proportion?" and your answer was, "He says in this table 'The rain is calculated as "'falling upon 122 square miles;' the absolute area "is only 102 square miles, and that of course contains "an enormous quantity of vacant land, parks and "squares, and places from which the rain cannot find "its way to the sewers. 'And 20 per cent. is allowed "'for evaporation, which is probably much in excess "'of the truth'; he assumes that the whole of the rest "falls into the sewers;" where does the rain go off the vacant lands and parks?—Into the soil, the greater part of it.

14,997. The whole of it, do you mean?—I did not say the whole of it. I said the greater part of it.

14,998. Do you mean to say that the quantity getting into the sewer is inappreciable?—It is very much reduced.

14,999. Do you mean that it is inappreciable?—I do not say so.

15,000. Do you represent to the Commission that the water falling upon the vacant lands, parks, and squares may be thrown out of consideration altogether?—I have never said so.

15,001. Then what do you mean by this statement: "that of course contains an enormous quantity of "vacant land, parks and squares, and places from "which the rain cannot find its way to the sewers"?—Because there is a very large proportion indeed of the parks and squares, the rain from which cannot find its way into the sewers; there are certain parts, such as the gravel walks, which are drained, and from which it does run into the sewers; but the greater proportion of the parks are grass and beds, from which it would not run into the sewers.

15,002. What proportion of rain falling upon parks and squares does fall into the sewers?—I have taken it in proportion to population.

15,003. That is not an answer to the question?—It is a very rational answer. Where the population is over 80 people to the acre, I have assumed the whole going in. Where the population is over 40 to the acre, I have assumed half going in, because the population is the measure of the space in regard to the roads and roofs of houses from which it will fall into the sewers.

15,004. Now, dealing with another question upon this subject of rainfall, you were asked by the Chairman at question No. 13,685, "Have we no direct "evidence from observation of the number of times "the storm overflows have been seen to be in action?" and your answer was, "Yes, Sir Joseph Bazalgette "has given that to you; but you must bear this in "mind, those observations could only be made at those "stations where, from there being pumping or other operations going on, the Board have men to observe. "Now, at question No. 7828, Mr. Baldwin Latham is "asked, 'Taking that district, how often would the "'sewers be incapable upon the south side?' to which "he replied, 'Upon the average, every time rain "'occurred the sewers must overflow in the case of "'London';" and in the next question his Lordship says, "I do not understand that 'upon the average "'every time,'" and you replied, "That is his answer. "Then he is asked, 'Whenever it rained?' to which "he replied, 'Whenever it rained at some point or "'other they must overflow.'" Do you mean to say that whenever it rained the sewer would overflow?—Those are Mr. Baldwin Latham's words which I quoted.

15,005. Now I will ask you, are you not aware that that referred to rain which was over $\frac{1}{100}$th of an inch an hour?—No.

15,006. Do you suggest that Mr. Baldwin Latham's evidence referred to whenever it rained, independent of the quantity?—I heard him say so; it is so reported in the notes; there is no qualification about it. If you make a qualification now, we shall understand it.

15,007. Then you go on to deal with the balance of available space remaining in the sewers. You say, "The high level sewer when the maximum flow is "taking place is only one-seventh filled." What do you make the discharge capacity of the high level sewer?—The total discharge capacity of the high level sewer is 16,620 cubic feet per minute.

15,008. We have always been told that the high level sewer discharged 11,000, and the middle level sewer 11,000?—These are the discharging capacities.

15,009. I am afraid you are putting before me some figures which I do not understand. What is this 16,620?—It is arrived at by our ordinary formula.

15,010. But Sir Joseph Bazalgette has given it over and over again that the discharge of the three sewers would be 33,000?—That may be the sewers taken at an upper point; but the lower point of the sewers would be beyond that quantity.

(*Professor Williamson.*) Would there not be a difference between the "discharge" and the "dis-

*Mr. H. Law.*

12 June 1883.

charging capacity"; because the one evidence goes upon the one, and the other upon the other?

15,011. (*Mr. Webster.*) No doubt you are right upon that, but we have proceeded upon the fact that from Abbey Mills to Barking there are three 9-feet sewers which take out 11,000 feet each?—But you were not asking me that, you were asking me the discharge of the high level sewer.

15,012. But I will ask you again, what is the discharging power of the three sewers before they are united?—The high level sewer and the middle level sewer, before being united, are 12 feet in width and 9 feet 6 inches in height; the sewer is in the form of a tunnel, an invert, two vertical walls, and a semi-circle.

15,013. I think the Commission have not had these figures before. Will you tell me what you say is the discharging capacity of the high level sewer?—It is 16,620 cubic feet per minute.

15,014. And what is the discharging capacity of the middle level sewer?—Also 16,620 cubic feet per minute.

15,015. And of the low level?—14,524 cubic feet per minute; calculated by the ordinary formula which engineers use.

15,016. Then the discharging capacity of those three sewers at Abbey Mills altogether is 47,764 cubic feet?—Yes, at their outfall, certainly.

15,017. And what is the discharging capacity of the three from Abbey Mills to Barking?—34,764 cubic feet per minute.

15,018. I do not at present understand what is the good of sewers which will convey 47,000 cubic feet a minute running into others which for a long length of miles would only convey 34,000 cubic feet?—You have never laid out a system of drainage.

(*Chairman.*) I think I can tell you how it is. The average discharge of that which receives the contents of the three sewers will be more regular than the average discharge of each of the three sewers separately.

(*Mr. Webster.*) No doubt your lordship can give a reason, but I respectfully submit that it is one thing to be wise after the event and it is another thing to deal with this as the rate of actual discharge.

(*Chairman.*) But what we are trying is, not whether Sir Joseph Bazalgette was wise before, but whether the sewers are sufficient now.

15,019. (*Mr. Webster.*) I am not trying Sir Joseph Bazalgette the least in the world; but what I am wanting to do is to show that the statement that the high level sewer is only one-seventh filled is not in accordance with the facts. (*To the witness.*) For what length will it discharge this 47,000 feet?—I cannot tell you exactly. I think it is for a quarter of a mile.

15,020. Are there any inlet sewers into it within that quarter of a mile?—Yes, of course.

15,021. I do not think it follows as a matter of course?—The high level and the low level sewers are sewers of interception and do receive at every point accessions of sewage. After they are united at Abbey Mills they cease to receive anything more, and become sewers of discharge.

15,022. But my question is whether any sewers run in after they pass the pumping station?—Certainly not.

(*Mr. Webster.*) I know that your lordship will naturally think I am asking about things which have been proved over and over again, and which I ought to remember; but it has been proved over and over again, in the evidence, that the high level sewer is 9 feet by 9, whereas the witness says it is 9 feet six by 12 feet. Now I asked Sir Joseph Bazalgette for the sizes, and he gave me distinctly what I have quoted to your lordship; but this is completely new, and therefore it is not my fault that I did not understand the quantity put by the witness. I find it stated in a former report "Between the "junction and the pumping station at Abbey Mills it "will consist of two parallel culverts each 9 feet in "height by 9 feet in width, and eastward of the "pumping station it will consist of three parallel "culverts each 9 feet in height by 9 feet in width."

(*Witness.*) I can explain that. The forms of the high and the low level sewers are shown upon Diagram No. 33, they are 12 feet in width and 9 feet 6 in height, the height being governed by conditions.

15,023. (*Mr. Webster.*) Is that all the way through?—No, at the lower end of the two sewers. Then they become united,——

15,024. But never mind about their being united?—That is what we are upon.

15,025. No, it is not. What distance back does the larger cross section go upon the high level?—I cannot give you the figure now. Those are then united into the two sewers I have mentioned. There are two of those sewers of 9 feet by 9 feet as far as Abbey Mills, and when they get to Abbey Mills there are three sewers of the same dimensions.

(*Mr. Norman Bazalgette.*) I see that Sir Joseph Bazalgette was asked at question 12,761, "Then the "high level, is that a 9 feet sewer?"; and his answer is, "That is 12 feet."

(*Mr. Webster.*) Let it be put upon a diagram which will show us the distance up of that 12 feet.

(*Witness.*) The diameter varies all the way up, it gradually increases in size.

(*Mr. Webster.*) I was astonished to find that the size of the high level sewer was put at 9 feet 6 by 12 feet, because some calculations which were given to me showed that the quantity of sewage in the sewer was largely in excess of the one-seventh; but when I was told the sewer was of the dimensions of 9 feet 6 by 12 feet, I saw that the calculation would not apply, and then I asked the witness if he was correct in the areas he had given me of the sewers, but I did not understand that at the lower end the sewer went out into a bell mouth or a larger size. I thought it was the same down to the point of junction of the three, my instructions were different.

(*Chairman.*) What would it matter whether it was a seventh or a fifth, in one case the sewer would have seven times the requisite capacity, and in the other it would have five times, and what would the difference be as regards this matter.

(*Mr. Webster.*) We do not consider that Mr. Law's statements are accurate.

(*Chairman.*) It does not matter if he is ever so inaccurate in a matter which is indifferent.

15,026. (*Mr. Webster to the Witness.*) Now, I want to understand your reasoning upon question 13,703,—do I understand you to say that the fact that people sleep out of London decreases the sewage?—Certainly.

15,027. It does?—It does.

15,028. Have you made any calculation to that effect?—No, I have not.

15,029. What do you mean by your answer to Sir John Coode. Sir John Coode's question was, "What we want to arrive at is this; although the "number sleeping within this particular district may "be affected, how far is the sewage affected?"; and you replied, "I do not suggest for a moment a "diminution of sewage, although I feel confident "there is one"?—I have not taken it into account, but I am confident that it is so, for the reason I stated in answer to the previous question, that people use the closets and take their baths, and so on, where they sleep and live, and not in the city.

15,030. Is it this,—that the sewage does not come into the metropolitan drainage at all, but goes to some different place?—In some cases it comes into a different place. Take, for example, a man who lives at Windsor, his sewage does not come in at all. In other cases it comes in at a different hour, take, for example, a man at Hampstead, his sewage comes in at a different hour.

15,031. Do you think that the number of people who have gone to live outside the metropolitan area is sufficiently large to make it a matter of consideration?—It is so; there are 8,000 acres, or a ninth

of the whole area, upon which the population is diminishing.

15,032. But you are not applying your mind to my question; have you any figures to tell us what the result of this sleeping out is?—I have not taken any estimate of it, nor taken any credit for it.

15,033. Now, in answer to question No. 13,720, and the following, you say a great deal as to the important facts which you said had been wholly lost sight of, and that is about these springs bubbling up from underneath the bed of the Thames. Was it from your own observations about these swallow holes that you had been speaking of the water coming into the Thames?—Some of them are my own.

15,034. Where are they?—In the Mickleham Valley.

15,035. Those are the Dorking ones?—Yes, and also the Barnet ones; those are my own observations.

15,036. And the Canterbury ones, too, of which you spoke?—No, those are not mine, those are Mr. Prestwich's.

15,037. Do you represent that the Canterbury one comes up into the Thames?—No, I do not represent anything of the sort.

15,038. I think you did, and I will read your answer. I will first ask you, with regard to the Dorking ones, do you represent those as going into the Thames?—Yes, certainly.

15,039. Underground?—Yes, feeding the chalk, and then coming out into the bed of the river.

15,040. Do not you know that they all appear again at Leatherhead?—No, I know they do not.

15,041. Of your own knowledge you say they do not?—I know they do not.

15,042. They do not appear again at Leatherhead and go into the Mole?—No, certainly not.

15,043. (*Chairman to Mr. Webster.*) I understand the effect of Mr. Law's evidence to be this: He said the rainfall shows a certain quantity of water. Making allowance of so much for soakage and so much for evaporation, and calculating the outfall of the streams, there is a balance left; that balance must have gone into the earth therefore and must reappear somewhere, because otherwise the earth would have become saturated to such an extent—in fact it could not hold all that has fallen since the creation. Then he says some of that must appear in the Thames and some go to other rivers. (*To the witness.*) Is that your argument?—Yes.

(*Chairman.*) I do not think the witness undertook to give the definite per-centage of the subaqueous or subterraneous water, but he says there is some.

(*Mr. Webster.*) As your Lordship has given what is the right view of the witness's evidence in chief, I would venture to suggest what is the contrary view.

15,044. (*Chairman.*) But I would like to put this to the witness. (*To the witness.*) Are you aware that there are wells in London which go down now 300 feet deep before they get to water, and that there is a necessity for going deeper and deeper still?—Yes.

15,045. How do you reconcile that with your theory?—That fact is owing to the large exhaustion that takes place in their neighbourhood by the many wells that there are in London and the time it takes for the water to travel to them. I have given your Lordship facts showing what the level of the water is, and that it takes time to travel and is exhausted upon the way.

(*Mr. Webster.*) In order that your Lordship may follow it, I wish to say that I do not agree with the statement which your Lordship put of Mr. Law's evidence, that it is based upon calculation as to actual rainfall. I say, if you look at the figures of the mileage and the quantity falling there, you cannot make that allowance, and I shall hope to show that Mr. Law is erroneous; that there is not that lost water which has to disappear underground.

(*Chairman.*) Do you say that there is not so much falls as he represents?

(*Mr. Webster.*) There is as much water falls, but it is not lost.

(*Chairman.*) You suggest that it comes down into the rivers.

(*Mr. Webster.*) That it comes down into the rivers and over Teddington Weir. Then I want to point out this, that Mr. Law did distinctly state that in his judgment the water absorbed by the Dorking and Canterbury swallow-holes reappeared in the Thames.

(*Witness.*) I never said anything of the sort. I gave the Commission no particulars of the swallow holes; in fact, I only referred to the papers where they might find a description of them as illustrating the extent to which the water might be absorbed in different places. I never said a word about the Canterbury ones coming out into the Thames.

15,046. (*Mr. Webster.*) I think I had better read to you the Answers to Questions 13,752 to 13,760. You were asked "The amount of rain which is absorbed "by these surfaces may be gathered from the fact "that there are 3,794 square miles of chalk exposed "which drain into the Thames basin. This is "according to Mr. Prestwich, who is looked upon as "the best authority upon that subject. If you take the "lower tertiaries, the chalk and the upper green sand, "all of which are pervious and admit the rain, we "have upwards of 4,000 square miles of country "which is absorbing a large proportion of the water "which falls upon it. (*Chairman.*) The upper and "the lower Thames valley?—Yes, altogether. Now I "would wish to point out this. In many parts, where "either the gault or the London clay meet the chalk, "the rivers which had been formed upon less pervious "strata disappear, being absorbed by the chalk. The "Mole is so called because of the swallow-holes which "exist between Dorking and Leatherhead. At Can-"terbury a very large number of swallow-holes exist; "at Farnham there are a very large number; at "Newbury, at Hungerford, and in the valley of the "Lea between Hatfield and Barnet, there are a series "of streams or rivers which have no outlet whatever, "but disappear, and are the feeders of the Amwell "Spring, which is in the neighbourhood. I have "coloured upon the ordnance the streams as they "exist. They have no outfall into any river at all, "and could not have been gauged by Mr. Baldwin "Latham. (*Q.*) Do you find these streams come to "an end as it were. (*A.*) Yes; at South Mimms "and at Mimms they have no other outlet than being "swallowed up in the ground. They are called "'swallow-holes' or 'swilly-holes,' and there is a very "large extent indeed of them in the River Mole. "There are some of them near Canterbury 50 feet in "diameter." And then at the bottom of the page you were asked "Your theory I understand is this, "there is the water and it must get away, otherwise "that which fell upon the land would be visible. "(*A.*) It must get away, and we find that the level "all round the margin of the river is at the mean "level of the water. (*Q.*) May not some of it get "to the sea," and you said, "an enormous quantity of "it gets to the sea."—Yes, but that is not saying that all of it goes to the rivers.

15,047. You state there that you know that 3,794 square miles of chalk drain into the Thames basin, is that your own figure or Mr. Prestwich's?—Mr. Prestwich's.

15,048. Is your 4,000 square miles the same figure, I presume it is?—Of course it is not, because one gives you the chalk and the other includes the green sand and the tertiaries, the lower tertiaries which are also pervious.

15,049. Now the 3,794 is a different figure from the 4,000, is it?—Yes, the 4,000 is the addition of Mr. Prestwich's figures.

15,050. Is the 4,000 then a figure also taken from Mr. Prestwich?—It is a rough addition of those figures.

15,051. Do not you know that the 3,794 includes the areas of the Orwell, the Stour, the Colne, the Blackwater, the Cam at Cambridge, the Little Ouse, which do not go to feed the Thames at all?—I will show the exact area which they do feed.

*Mr. H. Law.*
12 June 1883.

15,052. (*Chairman.*) That is not an answer to the question?—They do not include those areas.

15,053. (*Mr. Webster.*) Do not you know that the 3,794 quoted by Mr. Prestwich includes the areas of those rivers which do not affect the Thames at all?—No, some parts of the area which he gives do run across the ridge into other valleys, but the basin is limited by the gault. The basin is formed by the gault and the surface rivers are not those which conduct the water away in the chalk.

15,054. (*Mr Webster.*) I am putting a plain and simple question to you. Do not you know that the 3,794, which you quoted from Mr. Prestwich in support of your theory, includes an area or large areas which do not go to the Thames at all?—It is not my theory; Mr. Prestwich states that they do, it is his conviction of what comes into the Thames basin.

15,055. I will ask you to read it to me directly, if you say that is so; but first I will ask you, have you consulted Mr. Prestwich before you gave this evidence.

15,056. (*Sir John Coode.*) In Mr. Law's answer to Question 13,752, he says there are 3,794 square miles of chalk exposed which drain into the Thames valley?—I should wish to put the word "basin" instead of "valley" that is the only alteration, because the term "valley" may apply to superficial undulations, whereas the term "basin" will apply to the underground reservoir with which we have to deal.

15,057. (*Mr. Webster.*) Have you consulted Mr. Prestwich's book since you gave your evidence in chief?—Not at all.

15,058. Have you got the book here?—I have it.

15,059. Will you let me see it?

(*The witness handed the book to the learned counsel.*)

(*Witness.*) The basin is formed by the gault, and I have only gone to the same line as Mr. Prestwich has done.

15,060. Now I will ask you to show me any passage which goes to show that the 3,794 square miles are draining into the Thames valley?—I do not know whether I could pick out the place where it is succinctly put.

15,061. I am told you have picked out some streams which do not drain into the Thames valley.

(*Chairman.*) Making what difference?

(*Mr. Webster.*) I am told to the extent of 1,600 out of 3,794 square miles. (*To the witness.*) If you refer to page 59 you will find his reference to the 3,794.

(*Chairman.*) No one can blame you for going into this, because Mr. Law has put down everything he could in favour of those who called him, and therefore you have a right to efface, if you can, any of his figures; but, after all, the question is, does the river stink?

(*Mr. Webster.*) But your Lordship will bear in mind the difficulty in which we are. We have had a number of eminent witnesses called, and this suggestion of the underground water bubbling up has not been put to any of them, and yet Mr. Law comes and starts the theory that there is an extraordinary dilution of the sewage in the lower part of the Thames by the water of the underground springs.

(*Chairman.*) But after all, if you like to call Mr. Baldwin Latham, or any other geologist, to say that there are no bubbling up springs, so be it.

(*Mr. Webster.*) That is not quite the point; it is stated that the water does bubble up. Now, your Lordship knows, and we know, that the swallow-holes can be traced or found again, without, of course, pretending to say that some of the water does not go in that way.

(*Chairman.*) That would diminish the probability of their being a nuisance; but, after all, the question is if there is one. I have now given the reason why it is comparatively unimportant, and, of course, can only leave it to you.

15,062. (*Mr. Webster to the witness.*) Now, have you found any statement in Mr. Prestwich's book to show that the 3,794 square miles drain into the Thames basin, as you have stated?—The whole argument of Mr. Prestwich's book is that there is water which finds its way into the Thames basin, and those are the figures which he gives. The very title of his book is "A Geological Inquiry respecting the Water Bearing "Strata of the country around London."

15,063. (*Sir John Coode.*) Do you mean into the watershed of the Thames?—No, I mean the basin formed by the gault.

(*Sir John Coode.*) Without this explanation, I, for one, certainly should have understood this as applying to the watershed valley of the Thames, because it is very important, if there is this great difference which Mr. Webster points to, to have it cleared up.

(*Witness.*) I have shown upon this map, which I have put in, the gault which forms the basin of the Thames.

15,064. (*Chairman.*) Let me see if I understand you. Supposing the surface of the ground were hard, were covered with iron, or anything you like, you have comprehended an area larger than that from which the water would fall into the Thames, as the other side suggest?—Yes.

15,065. But because you say that outside such an area as I describe there are impermeable walls or barriers of gault, therefore you had the right to take something more than the surface, because when the water which falls upon the other side of the watershed gets down some depth it will come into contact with this gault, and will be driven in an opposite direction?—Yes. The section I put in quite illustrates my meaning, that is, that the chalk being so pervious, the water penetrates to a lower surface, which is inclining, perhaps, in another direction from the chalk, and does not flow as the surface of the chalk would lead you to expect.

15,066. (*Mr. Webster.*) You quote 3,794 miles of chalk exposed which drain into the Thames basin; that 3,794 is quoted from Mr. Prestwich, is it not?—Yes, he is the authority for the surface area.

15,067. Will you kindly refer to page 59 of Mr. Prestwich's book, and I will read this to you. The 3,794 square miles which is quoted by you in support of his theory is taken from Mr. Prestwich's book, and this is the passage. "Taking the whole of the chalk "district surrounding the tertiary tracts of Kent and "Surrey, along with that portion in Hampshire and "Wilts which lies north of a line drawn from Alton "to Devizes—of Berkshire, Oxfordshire, Bucking-"hamshire, Hertfordshire, Essex, Bedfordshire, Cam-"bridgeshire, and of Suffolk, as far north as a line "drawn from Newmarket to Woodbridge,— it forms "an area of about 3,794 square miles"?—The reasoning in this book is that that is what is supplying the basin of London for the purpose of determining how far that strata would be suitable for the purpose of supplying London with water.

15,068. I think you are unintentionally misrepresenting the intention of Mr. Prestwich's book. Do you represent, for the purpose of your argument which you have been laying before the Commission, that the land going as far north as a line drawn from Newmarket to Woodbridge has anything to do with the question at all?—Yes. I say the water in the Thames basin does not depend entirely upon the inclination of the upper surface but upon the inclination of the lower surface, the gault which confines the water. It penetrates perpendicularly through the chalk till it meets with the gault, supposing there is no exit, or until it meets with the stream of water in the chalk. But I said that an enormous quantity of this chalk water went into the sea and not all of it into the river.

15,069. (*Sir John Coode.*) Can you give me the upper edge of the gault, because that seems to be the determining area. You say the water permeates through the chalk until it meets with the gault, so that the area of the upper edge of the gault is the determining area?—It is 7,891 square miles.

15,070. (*Mr. Webster.*) Where do you find that?—That is at page 98 of Mr. Prestwich's book.

15,071. But I think you have included the lower green sand?—The lower green sand should come out.

15,072. (*Sir John Coode.*) And the area of the gault itself?—That would depend upon which way the gault fell. All that fell towards the Thames basin would come into the Thames.

15,073. You are obviously wrong in including the 7,891?—That is so; it should be about 7,000. I only looked at it casually.

15,074. (*Mr. Webster.*) I observe that your answer to question 13,738 assumes that the geological conditions of the upper Thames valley are the same as of the lower?—Yes.

15,075. Do you say that they are in fact?—No, but it would require a very large examination to tell which way they should go.

15,076. I am not saying whether it tells in your favour or against you, but I ask you, have you any facts upon which you can justify your assumption that they are the same?—No, certainly not. As I say, this was merely to show that there was only half the rain allotted to the Thames below Teddington that came above. That could not be so, because there are no disturbing elements which make that difference, and it would be in face of the fact that we know that the water comes into the Thames, because we can see it in many places; but I have not gone into the question of the way in which these geological conditions would affect the matter.

15,077. Now do you know yourself, from your examination of geological books, how much of the water absorbed by the swallow-holes reappears upon a lower level of the same stream, or upon a level adjacent to that?—No, nor do the geologists who have written upon the subject.

15,078. From your own observation have you any illustration of swallow-holes where the water absolutely disappears and cannot be traced at all?—Yes; those in the Mole cannot be traced.

15,079. Do you say that there is no connexion between the disappearance and the reappearance at Leatherhead?—Yes, I say the quantities which reappear are not at all equal to the quantities which disappear.

15,080. Will you tell me upon what quantities you base that statement of yours?—Upon no quantities at all.

15,081. Now the Stour swallows reappear in the Stour, do they not?—I do not say that they do, but I state that a large quantity of the water which has been absorbed by the chalk does reappear in the bed of the Stour.

15,082. You may say it now. I do not see it in your evidence-in-chief?—It is so as a fact, and I so stated in answer to Question 13,756.

15,083. Now in your answer to Question 13,766, you have called attention to the differences between Mr. Mansergh's and Mr. Baldwin Latham's figures. Do you know that Mr. Mansergh took Sir Joseph Bazalgette's figures, and that Mr. Baldwin Latham made an independent calculation of his own. Did you know that when you occupied the time of the Commission?—I know nothing about it beyond that they differ.

15,084. And you did not take the trouble to ascertain that Mr. Baldwin Latham had made his own calculation of the actual water supply from the water companies' supplies, and that Mr. Mansergh had taken Sir Joseph Bazalgette's figures, and that that was the discrepancy between them?—But where has Sir Joseph Bazalgette given those figures?

15,085. But will you answer the question; did you know that?—How could I know it?

15,086. I merely point out the discrepancy. Professor Unwin has taken them differently again. He has taken 26,900,000?—Yes.

15,087. I will explain it all. Now will you look at Question 13,805, where you say, "Now if we take "the mean of the sea water at Brighton, at Penzance, "and other places, and in the Atlantic, as given by "Dr. Frankland in his Table No. 3, we get at 1,900, "which is nearly identical with Professor Way's "mean; and curiously enough in the mid-Atlantic "Dr. Frankland gives only 1,800." Will you tell me where you took that from?—I took that from Dr. Frankland's own tables.

15,088. Will you show me where he gives his mid-Atlantic water as 1,800. I am told that the lowest mid-Atlantic figure of Dr. Frankland for chlorine is 1,987?

(*Chairman.*) Does it matter what it is in the middle of the Atlantic?

(*Mr. Webster.*) It does not matter a bit, except that we have a theory built up upon a number of these tables, and I was told that the effect of Mr. Law's evidence was such that I ought to meet it.

(*Chairman.*) But suppose this passage were struck out, should we be any the less deficient in information to enable us to come to a conclusion in this matter.

(*Mr. Webster.*) I do not wish to pursue it.

15,089. (*Chairman, to the witness.*) If Dr. Frankland said 1,800, do you consider it a mistake, or that he is right?—I have no reason to suppose it is a mistake; he has given it in his Table No. 3 in grains per gallon, and I have reduced it to proportional parts; that sample was taken in January 1882.

(*Mr. Webster.*) I am told by Dr. Frankland himself that the lowest he has taken for mid-Atlantic water is 1,987.

15,090. (*Chairman, to the witness.*) These are your figures that I see upon the table?—If you divide the grains per gallon by 7, and move the decimal one place, that will give you the proportional parts to the hundred thousand, and that is what I have done.

(*Mr. Webster.*) I am told that that is a quotation from Dr. Frankland's table in the 6th Report of the Rivers Pollution Commission, page 132, in which it is distinctly put down at 1,987.

(*Witness.*) All I can say is that I remember Dr. Frankland being cross-examined upon that very figure; and this mid-Atlantic sample is taken in January 1882, whereas this 6th Report was printed in 1874, therefore it is impossible for that table to be a quotation from this Report: the date shows when the sample was taken, and a sample taken in January 1882 could not be put in a table in a Report that was printed in 1874.

(*Chairman.*) It seems to me manifest that what Dr. Frankland said about the middle of the Atlantic is of no consequence, whether it is a mistake or not; but in addition to that it relates to this chlorine, which does not affect us in any way except as far as relates to the upper part of the river. I think we are all agreed that that is a matter which is not really brought before us by the evidence.

(*Sir John Coode, to Mr. Webster.*) Would it materially affect your view of the question if we took the quantity of chlorine as somewhere between 1,950 and 2,000?

(*Mr. Webster.*) Not at all.

(*Sir John Coode.*) Anything beyond that is splitting hairs.

15,091. (*Mr. Webster.*) That is quite our view. (*To the witness.*) Now you were asked at the beginning of you evidence, on the second day of your examination, at No. 13,847, "I believe first of all you "wish to add something or to say something about "the observation you made yesterday with respect to "the capacity of the outfall sewers," and your answer was, "I wish to say that we have since ascertained "the quantity of rain which fell last Saturday I find "that between 9 in the morning and a quarter after "12 in the day, $\frac{17}{100}$ths of an inch of rain fell, and "between half-past 4 and 6, $\frac{15}{100}$ths, making together "$\frac{1}{3}$ of an inch in $9\frac{1}{2}$ hours, and that although only "two out of the three sewers were at work, no over-"flow occurred at any part of the system"; is that of your own knowledge?—No, that fact was given to me by Sir Joseph Bazalgette.

*Mr. H. Law.*

12 June 1885.

15,092. Now I must put it to you pointedly. Are you aware now that the Blackfriars sewer was overflowing the whole day?—No.

15,093. Would you kindly make a note of that, in order that inquiry may be made, because I am sure you would state what is accurate.

(*Chairman.*) I think you have a perfect right to say that he does not know it of his own knowledge, and that Sir Joseph Bazalgette ought to be called to prove it.

(*Witness.*) It will be of course better for Sir Joseph Bazalgette to give you that.

15,094. (*Mr. Webster.*) You have made a distinct statement that no overflow occurred at any part of the system?—I could not know it of my own knowledge.

15,095. Now see, in answer to Question, 13,849 it is stated that it is absurd to suppose that the city calculation can be right, because there would be 12 per cent. of sea water at St. Paul's Pier. Now do you not know from the actual reports before Parliament that the Lambeth Waterworks Company always took in their water upon the ebb?—Very likely.

15,096. But I call your attention to this; you say it "is almost an incredible thing. Up to a few years "back, the Lambeth Waterworks took almost the "whole of their supply from a point close to Waterloo "Bridge, from a point very little above the point "where it was alleged that the water was liable to "have 12 per cent. of sea water in it"?—They took it in as far as they could upon the ebb, but they were not able always to do so.

15,097. One word about your own knowledge of the matter. In the first place do you know that they always, as far as they possibly could, did take in at the ebb?—Yes, they did do so.

15,098. It could not be 12 per cent., you say?—Or anything approaching it.

15,099. But you did know at the time that they took it in as far as they could upon the ebb?—Yes, as far as they could.

15,100. What knowledge have you of your own or from Statistics that they did not always take it upon the ebb?—I can only refer, ——.

15,101. Refer to anything you like, what facts have you got, either statistics or statements in any Report, to show that they ever have taken it in except upon the ebb?—I can refer to the Water Reports upon the subject which I must do, and I cannot do that at the present moment.

15,102. But you told us just now that they did as a matter of practice take it in upon the ebb, and not upon the high water as your quoted answer assumed?—Yes, as far as they could.

15,103. Now one other thing which is perhaps quite as important, when you say, "or anything ap- "proaching 12 per cent. of sea water," what do you mean by that?—That anything approaching 12 per cent. of sea water would not be such as could be drank.

15,104. Did you mean one per cent.?—No, one per cent. might be drinkable.

15,105. Two per cent.?—Indeed I could not tell you; if I were to mix it, and then taste it, I could tell you perhaps, but I could not do so offhand.

15,106. What parts per 100,000 of chlorine would 12 per cent. of sea water represent?—I cannot tell you, but it is not only the chlorine; the worst of all is the sulphate of soda which gives the bitter taste, that is what would be most readily detected and would render it most nauseous, not the mere salt.

15,107. I want to get from you what proportion of sea water could be ascertained if mixed with drinking water. I want you to pledge your scientific opinion?—That I cannot tell you.

15,108. But you have told us that this city evidence cannot be believed, because that company took their supply upon the flood, and not upon the ebb, whereas I put it to you that they took their supply upon the ebb, and I put it also that this quantity of sea water could not be detected; if you think this quantity could be detected I want to know what could not?—I would say that 12 per cent. would be such a quantity that could not be drunk, but I could not go down to a point where it will not be nauseous.

15,109. Then your idea is that this water was delivered straight away to the customers without being mixed with anything else?—That the water was not mixed with other water.

15,110. But do you mean to say it was delivered away without being mixed with water which did not come in at high water?—No, I do not say that.

15,111. Then upon what ground do you say it could not be true, because the 12 per cent. must have been detected or would be so nauseous that it could not be supplied.

15,112. (*Chairman.*) Have you ever drank a mixture of fresh and sea water?—I have taken it sometimes involuntarily when I have been bathing, but I have not tried a course of experiments to ascertain how little I could taste.

15,113. (*Chairman.*) In plain English, do you know any more about it than any of us here?—No, not at all.

(*Mr. Webster.*) Now you made a very remarkable statement in answer to question 13,863, when you spoke of the chemical composition of the water in the river.

15,114. (*To the Chairman.*) I have said, my lord, that I did not want to put unnecessary questions; but if I have to comment upon these matters afterwards, I hope it will not be said by my learned friends that I have abstained from touching upon various points, because I have, in deference to the views of the Commission, abstained from asking questions upon points with which, as far as argument is concerned, I can deal hereafter. (*To the witness.*) Now you have stated in answer to question 13,863, "Now comparing that," that is to say, the water at North Woolwich, "with the filtered water delivered by the water "companies for drinking purposes in London, the water here is nearly as pure." I see you have given the organic carbon; do you represent that organic carbon is what determines the fitness or the purity of the water for drinking purposes?—No, I was going on to give the organic nitrogen when I was stopped.

15,115. I really do not think you were, if you will pardon me for saying so?—Yes, that was so. Lord Bramwell asked me the question. He said at 13,866, "What have we to do with what water the people "are drinking." I was obliged to take all these things briefly.

15,116. Just tell me what the organic nitrogen was; was it ·123?—Yes; I have stated that before.

15,117. But what is the organic nitrogen in the water delivered by the company?—It is ·09.

15,118. You do not suggest that the ·09 is the ordinary average of water delivered. You say that that is the highest you have got?—I gave it as a measure of the state in which the river was.

15,119. Let me look at the table of organic nitrogen that you have got, if you please, showing anything as high as ·09. I am told the average is ·03?—I have a great many much higher than that. Upon the 20th of March, 1883, this present March, the water drawn from a tap of the West Middlesex as delivered by them contained ·099 of organic nitrogen.

15,120. Whose report is that?—The report of Dr. Tidy, Dr. Odling, and Mr. Crookes.

15,121. I see in your answer to question 13,863, "Now comparing that with the filtered water "delivered by the water companies for drinking pur- "poses in London." Do you mean to represent that as the average or the maximum?—I meant that as representing the water which was delivered occasionally by the water companies.

15,122. ·03 is the average, is it not?—That I cannot tell you. I have several here which are very much higher.

15,123. I should like you to give me the average of what you have got?—I have taken out the high ones, and therefore they would not be the fair ones to give.

15,124. Now I put it to you at once. Taking the organic carbon, taking the organic nitrogen, and taking the other chemical constituents, do you represent that the water at North Woolwich was as good as that delivered by the water companies?—What I do say is that the water at North Woolwich upon that day, which is the day when it is stated to be exceptionally bad, and therefore we are not taking the average of the Thames. I say that the water of that day at North Woolwich contained no more organic carbon than the water which is filtered and delivered, and 75 per cent. of the organic nitrogen.

15,125. As usually delivered?—No, as occasionally delivered.

15,126. I think I may be pardoned for putting this to you. You have quoted Dr. Frankland, at question 13,889, as suggesting that four-fifths of every drop of rain, however slight, goes into the sewers. Now I ask you either now or at any other time, because I know Dr. Frankland's view about that, to point out any answer in which he said anything of the kind?—It is his report as put in.

15,127. Can you refer us to any passages of it?—He refers to table C., and he says he has calculated in table C. the rain falling upon 122 square miles, and he has deducted 20 per cent. to allow for evaporation, and has taken four-fifths of the whole. If you turn to table C. you will see, as I mention, that when one-hundredth of an inch of rain falls, he, acting upon this suggestion, has assumed that the increased quantity delivered by the sewer would be 14,000,000 gallons per day.

15,128. I put it to you, as Dr. Frankland explained to my learned friend Mr. Bidder, is it not a table prepared upon the give-and-take principle, that when there is a much heavier rain the same principle is taken?—No, it is all give and no take. Every quantity is taken out and multiplied into the quantity of solid matter increasing in geometrical ratio.

15,129. You called attention to Mr. Mansergh's diagram of the condition of the river at Erith?—I am not aware that he put in any such diagram.

15,130. At question 13,930 you say "A longi-"tudinal section of the river was put in by "Mr. Mansergh." Now will you listen to this, you agree, do you not, that with the Dagenham shoals removed, without the mud upon the south side, the river was larger in its section in Halfway Reach than was required, that is to say, larger than the cross section below originally?—I agree with that.

15,131. Do you also agree that in 1878 when the mud was there, the cross section of the river was too small, however the mud got there.

(*Chairman.*) How was it too small.

(*Mr. Webster.*) That there was a larger section above it.

(*Chairman.*) You mean that actually and in fact it was not big enough.

15,132. (*Mr. Webster.*) That actually and in fact the cross section of the river and the water space was smaller than the sections above it considerably. (*To the witness.*) Do not you agree that measuring the cross sections in Halfway Reach in 1877, with the mud, the river was constricted at that point?—Not at the southern outfall itself.

15,133. At the same corresponding point, if you please, that Mr. Mansergh referred to?—Then I do not know what exact point he did refer to. (*The witness referred to his diagram.*)

15,134. You know the mud constriction to which Mr. Mansergh refers well, do you not?—The section does not give me that information.

15,135. Is there shown upon Mr. Mansergh's section a constriction of the river in the year 1878, where previously there had been no constriction?—It shows the accumulation of the mud.

15,136. And a constricting of the area?—It is less than it was before, of course.

15,137. In 1882 had that become still smaller?—That I cannot tell you from my own kowledge.

15,138. You see Mr. Mansergh's diagram showing that it becomes smaller. Do you say it is not correct?—I will not say it is not correct.

15,139. Assuming that it becomes smaller, does not it follow that that deposit must be of such a character that if the floods should sweep it away it would re-deposit in the ordinary currents?—No, because at the point where the largest accumulation has taken place the velocities of the current is even now far too weak; the area is too large. Although there are one or two points where there is a stronger current for a short length it is not sufficient to affect the deposit upon the south side.

15,140. You have not followed me. I should have thought your answer was the strongest proof that whatever were the strength of the currents, assuming the floods were sufficient to wash the deposit away, the deposit would be re-deposited in the ordinary currents afterwards?—I do not understand the question. The section before Sir John Coode will show the currents, and though there are one or two points where the stream is strong, it is not sufficient to prevent a deposit upon the south side where that stream does not run.

15,141. Are you not aware that the cross-section in 1882 is smaller than the area of the section before the dredging of Dagenham shoal had been commenced?—I cannot tell you that.

15,142. Assuming Mr. Mansergh's diagram to be true, that is so, is it not?—I do not know; there is no date showing when his normal bed of the river was taken. I am sure that cannot have been taken before the Dagenham shoal was removed; that is to say, that the line in black shown upon Mr. Mansergh's cannot be the line of the section of the river before the Dagenham shoal was removed.

15,143. Can you give me the area of the river before the Dagenham shoal was removed?—I have put it in, in a table and a section also.

15,144. (*Sir John Coode.*) Where is that?—It is on page 14 of the second day's evidence.

15,145. (*Mr. Webster.*) Which is the one you say shows the cross-section before the Dagenham shoal was removed?—My diagram No. 10 shows that.

15,146. Will you give that to me in square feet. I put it to you that the cross-section in the autumn of 1882 is smaller than you make it. You say it is not so. I can test it very well if you will give me what was the area of the cross-section in square feet prior to the Dagenham shoal being removed?—The area in square feet at half ebb was 40,927.

15,147. That, you say, is prior to the removal of the Dagenham shoal?—It is prior to the removal of Dagenham shoal.

15,148. That is D.D. upon your diagram?—Yes.

15,149. What do you say is the actual area at D.D. now at half ebb?—It is somewhere about 56,000 or 58,000; I am not sure exactly how far it corresponds with my No. 29 or No. 30; No. 29, which is the southern outfall, is 56,501, and No. 30 is 58,545.

15,150. But I am asking you about D.D., a corresponding point. You have put D.D. upon your own table?—Yes, but I have not got the present area of D.D. exactly until I have the line corresponding to it in the cross-section.

15,151. Do you say D.D. corresponds with Mr. Mansergh's cross-section?—He has not given a cross-section.

15,152. But you must see the necessity of making it clear to me.

15,153. (*Sir John Coode.*) Does Mr. Mansergh give the areas?—He gives the relative cross-sections, but I do not think he gives the areas.

15,154. I understand you to say it is somewhere between 56,000 and 58,000; is that your answer?—Yes, that is it; but I can give it exactly to-morrow

*Mr. H. Law.*
12 June 1883.

(*Mr. Webster.*) I will take that; but it does not follow because you take 56,000 here and 58,000 there that the particular point would be between the two.

(*Witness.*) I will give it exactly to-morrow.

15,155. (*Sir John Coode.*) You know the point if Mr. Webster wishes to have it?—Yes, I do.

15,156. And you will give it him to-morrow?—I will.

15,157. (*Mr. Webster.*) You have said that the sewage is discharged into 261 times its bulk; that is in answer to question 13,855?—Yes.

15,158. That statement is upon the assumption that it goes into perfectly pure water, is it not?—No, into the river water as analysed by Dr. Frankland.

15,159. I do not think you mean that?—I do mean that.

15,160. You say it goes in as 1 to 261, taking the water as it is?—Yes.

15,161. That is your statement, is it?—Yes; I say the sewage bears a ratio to the quantity, which passes upon an average tide of 1 to 261.

15,162. But that is assuming for the purpose of comparison that it is pure water that it goes into, is it not?—Certainly not; my argument is this: Dr. Tidy says, it is sufficient to have 20 parts of pure water, and I say that that water is sufficiently pure to allow 261 parts to do the work which 20 parts of pure water would do.

15,163. That, taking its impurities, 261 parts will do the work of 20 of pure water?—No, I do not say that, but you must take my whole argument.

15,164. We must have it one way or the other. Do you mean by your 1 to 261 that it goes into 261 times the quantity of water which will do the same amount of work as Dr. Tidy's 20, or do you mean that it requires as 261 is to 20 to do the same amount of work?—What I mean is, that, assuming 20 parts of the water delivered by the water companies to be sufficiently pure to purify the sewage (because we have no distilled water in the Thames, and Dr. Tidy, when he says "pure water," does not mean "distilled water,") 261 parts of the water of the river will do it.

15,165. (*Sir John Coode.*) I understand Mr. Law's argument to be, that he has got 13 times the quantity of fresh water which Dr. Tidy considers sufficient. (*To the witness.*) Whatever may be the value of that argument, that is it, is it not?—Yes, that is it.

15,166. (*Mr. Webster.*) I am told I ought to put to you question 13,788, in which you refer to the rate of traverse of the water on the 7th of September. How is that calculation arrived at; is it by taking the quantity of water on the 14th and working backwards?—Yes.

15,167. Now, if you had worked from the 22nd back to the 15th ——?—I have nothing to do with the 22nd.

15,168. I am only dealing with your own proposition. If you had worked from the 22nd back to the 15th, that would have shown a very different result, would it not, because you had 109,000 coming over on the 15th?—Very likely; but I have not gone into that at all.

15,169. (*Sir John Coode.*) Was that assumption of a week based upon any facts at all approaching the state of things which really exists?—No.

15,170. It was a pure hypothesis?—It was merely to show this, my argument was, that to take that day's fall over Teddington Weir is obviously wrong. If you went a week back that would at once reduce the quantity of sewage by half.

15,171. But supposing you went three days back, what would you find then; it would all turn upon your assumption of the week being correct or not?—Yes, and depending upon a great number of other circumstances as well as what the quantity of water coming down is.

15,172. If you had taken any other dates you would have had a very different result?—Yes, certainly. It all goes to show that the calculation is of no value.

15,173. (*Mr. Webster.*) I notice you have given some evidence about the mud; you have read a report of the state of the river in 1839; have you from any actual observations of your own, or is that what the chemists are going to say, gone into the question of what the mud is made of at Erith?—Not into its chemical composition.

15,174. Do you represent that it does not smell any more than common mud?—I represent it has no smell at all, unless you take it out of the sewers which are trickling over the surface; even on warm days it has no smell whatever, but that is a point upon which, of course, the Commission can judge for themselves; it has merely the smell of earth.

15,175. With regard to your evidence in answer to questions 13,960 and 13,961, as to the condition of the river in 1839 and the draining of the houses into cesspools, what number of sewer outfalls were there in 1839, do you know, above London Bridge?—I do not know that.

15,176. Were there not 140 in the year 1828?—There were a very large number of sewers, but you must bear in mind those were all sewers which had been there for 100 years to drain the streets; it does not follow that they came from the houses.

15,177. But what I put to you is, were not they sewers which, as far as one can gather from the reports, were discharging sewage matter?—To a certain extent. At that time it was illegal to put sewage into the sewers; it was contrary to the law, but nevertheless they did it surreptitiously; all the streets were sewered, but they were not intended to take house sewage.

15,178. (*Sir John Coode.*) As a matter of fact, they did take house sewage?—Yes, to a certain extent.

15,179. (*Mr. Webster.*) You mentioned the refuse from water-closets being carried in surreptitiously, when were water-closets invented by Bramah, was it in 1778?—No, it was later than that; I remember Bramah very well, and I was not alive in 1778.

15,180. But it does not follow that he died immediately after he had invented the water-closet?—It was much later than 1778 that they were invented.

15,181. Do you gather that there is the same rainfall in the upper Thames as in the lower Thames?—Certainly not. I have given you the relative quantities taken from Mr. Symon's table; I took his figures.

15,182. (*Prof. Williamson.*) There is one matter upon which you would, perhaps, be kind enough to give the Commission some further explanation than you have given us yet, as to the way in which you have obtained your figures in relation to the water which you conceive to percolate through the chalk into the river. With regard to the opinion you have expressed, that water enters the Thames as filtered water, which has fallen upon the chalk at distances from the Thames, and which is prevented from escaping elsewhere, on account of the gault, which underlies the chalk, you have included in your estimate of the water which is likely to reach the Thames (of course making allowance for evaporation) a good deal of that area which is beyond the actual valley of the Thames, have you not?—No, I have not used those areas in any way in my calculations. I mentioned the area simply to illustrate the large area which led water either to the Thames or to the sea. What I did to determine the quantity was this. I took the quantity over Teddington Weir, which contains that which comes in from springs in the upper part of the river. I then found that after making allowance for the difference in rainfall, the quantity gauged was not more than half below what came off above; that was the result of my calculation. Then from those data I determined the quantity which would come into the river, but not by taking any area, and assuming a percentage of the rain which fell upon that area as coming out.

15,183. But I thought in your answers to cross-examination you had referred to the gault as giving the limit within which the water was, to some extent, available for the Thames?—No; you will find that

I say that enormous quantities of water falling upon that area find their way to the sea.

15,184. Are there not other rivers than the Thames within the basin of the Thames?—Yes, there are.

15,185. (*Sir John Coode.*) That is to say, outside the Thames watershed proper, but within the area of the gault?—Yes, that is so; and you will find that the whole of these rivers are very small compared with the area of the country they drain. If you take the size of the bridges in the chalk country you will find they are nothing to compare with what they are in the clay country, and you will find that many of them owe their origin to the water that flows down the upper end of them from the clay. You will find that a very large proportion of the chalk country has very little water in it, nearly the whole of the water being absorbed, and only small rivulets existing.

15,186. (*Mr. Webster.*) Would you tell us what the Dart and the Cray are alone. Do you know that the Dart and the Cray are 5,000 cubic feet a minute, which, according to your own account, would drain 200 square miles?—They drain a very large area. There is a break in the centre ridge of hills, and the Darenth runs through, and takes the large area adjoining the Medway. It is very remarkable that the ridge is broken, and that the rivers, the Mole, the Darenth, and the Medway, all go through the fracture in the ridge or backbone that goes through the country.

Re-examined by Mr. Norman Bazalgette.

15,187. I will just ask you a question about the condition of the mud below the outfalls. As a matter of fact did you examine the mud below the outfalls as recently as last Saturday?—I went down the river last Saturday.

15,188. Will you state what the weather had been for some time preceding your visit to the outfall?

(*Mr. Webster.*) This does not arise out of my cross-examination.

15,189. (*Mr. Norman Bazalgette.*) You asked the witness whether the mud smelt, and I am going to ask how it was upon that occasion. (*To the witness.*) What had been the condition of the weather previously to that?—It had been dry weather for some time, and was very warm. We carefully took up the mud in front of the Corinthian Club at Erith, and from every place where it had been described as being derived from the human frame. A very large portion of it was lying there, and there was no smell in it whatever, except the ordinary smell that you have in mud.

15,190. (*Sir John Coode.*) What time of the tide was it you took the samples of mud?—It was low water.

15,191. And at what distance from the low water edge?—All the way up where we could find it.

15,192. All the way up beyond high water?—There is no mud beyond the high water. We had also an excellent view of the springs of the chalk water running out at Erith, a very excellent view indeed of them which the Commission themselves will have whenever they go to see the river at low water.

15,193. (*Mr. Norman Bazalgette.*) Did you see any bubbling out through the mud?—Yes, out through the sand, rather. There is a large quantity of bubbling through the sand, which I believe to be air and not noxious bubbles,—bubbles of air which I think does arise from the difference of pressure of the water at high and low water.

15,194. My learned friend asked you a good many questions about swallow holes and subterranean springs which find their way into the Thames; but I will ask you, even assuming you are not quite accurate as to the area in which you say this subterranean water arises, is it a fact that there is a large area from which subterranean water finds its way to the Thames?—Yes, but I repeat that I gave the area only as that which gave part of its water to the Thames, because I said an enormous part of it went to the sea; but I say it is the water which flows down the Thames basin and charges the chalk which I am considering.

15,195. I think you have told us that in order to make the chlorine tests of any value whatever, this subterranean water ought to be taken into account?—It should.

15,196. Has it been taken into account?—No, and the great importance of that is, in the dilution of the sewage with pure upland water.

15,197. Now, you were asked with regard to question 13,661, upon what data you say that 180 feet a minute represents a high velocity, what do you say to that?—We consider 120 feet through the sewers is a very good velocity.

15,198. Is that known to be a self cleansing velocity?—It is known to be a self cleansing velocity.

15,199. And if 120 is held to be a self cleansing velocity, 180 is a high velocity?—Yes.

15,200. Now about the number of storm overflows indicating the non-capacity of the main drainage system; my learned friend asked you how you could say that the main drainage system was sufficient as it was estimated in the first instance, having regard to the number of storm overflows which have been recently added to it?—To that I say that they are not so much storm overflows as relief sewers, extending a considerable distance inland.

(*Sir John Coode.*) But relief sewers into the Thames, else I do not see where they could go.

15,201. (*Mr. Norman Bazalgette.*) As a matter of fact, have not many of the natural water courses which formerly took the rainfall now been filled up?—Yes, as for instance, the Effra and the Hackney brook.

15,202. Therefore it has been rendered necessary to substitute artificial watercourses for them?—Yes, as they have built over the old streams and occupied their sites, it has been found necessary to provide relief sewers in place of the old natural brooks, that has been found necessary in the case of the Quaggy, the Hackney brook, the Effra, and others.

The witness withdrew.

Mr. Edward Easton examined.

15,203. (*Mr. Norman Bazalgette.*) I need hardly ask whether you are a civil engineer?—I am.

15,204. Are you well acquainted with the River Thames below London?—Yes, from the fact that for the last 25 years I have acted as engineer for the Commissioners of Levels extending from Woolwich to Gravesend for the preservation of the banks. I am also engineer to the Commissioners of the Navigation of Dartford and Crayford Creeks, and as such I have constant opportunities of inspecting the banks of the river, and of knowing what is going on on the banks and the beach, and on the shore of the river generally.

15,205. You are also engineer to the South Essex Waterworks Company?—I am; that is, on the north side of the river at Grays, and I have also constructed works at Gravesend for the supply of Gravesend with water.

15,206. I believe you have designed and constructed a good many engineering works of different kinds on both sides of the river?—Yes, I have had several other works under my charge, the pier at Grays, for example, and other works of a different character.

15,207. The first question I will ask you is this: in your judgment, are the positions which have been selected for the outfalls of the drainage of London suitable positions?—It seems to me that at the time these works were designed no more suitable positions could possibly have been found, and I do not think

*Mr. E. Easton.*

12 June 1883.

that the circumstances have so far changed as to lead one to change one's opinion. The river the whole way below Barking is bounded on both sides for a great distance by wide marshes, and, until you reach the town of Erith on the one side and Purfleet on the other, those marshes are generally from one to two miles broad. At the time that the outfalls were made there was scarcely any habitation whatever of any consequence, except at Gravesend, on the banks of the river, and it appears to me that therefore this site was chosen with great judgment. Besides this, from time immemorial, I may say, there have been a variety of, one cannot call them anything else but stinking trades, established upon the banks of the river between the two points Greenwich and Purfleet, and for that reason, if there should be any extra nuisance which would perhaps be inevitable from the discharge of the sewage of so large a city as London, it would become to a very great extent modified and, in fact, overpowered by the other nuisances which are already existing there. And for that reason I say that, in my judgment, the sites were well chosen.

15,208. I believe that since the outfalls were established Erith has enormously increased both as regards population and buildings?—Erith is the first point at which the high ground touches the river, before that, the shore of the river and its banks are such as I have described, but at Erith the high ground touches the river, the country is very beautiful, and there the population has increased, as the Commission know very well, and a certain class of residential property has sprung up both at Erith and between Erith and Woolwich, which has changed the general character of the population from that which I have just before described.

15,209. Can you tell me whether in the neighbourhood of Erith especially there are a number of these nuisance factories of which you were speaking just now?—There are a great number, as has been given in evidence; they are well known to me, because I have to pass them frequently in making my inspections upon the river.

(*Sir John Coode.*) We have only heard of one at Erith.

(*Mr. Norman Bazalgette.*) I put it to the witness "in the neighbourhood of Erith."

(*Witness.*) I am speaking of what we call the Erith Marshes, which extend from Woolwich to Erith.

15,210. (*Mr. Norman Bazalgette.*) Now can you tell me what is the sanitary condition of Erith as regards its own natural drainage?—I think the Commission have before them a report, which I made in 1877 and 1878, as regards the sanitary condition of Erith. The works which I recommended in that report have not been carried out, and I am not aware that the condition of Erith has improved in any way.

15,211. (*Sir John Coode.*) You think the state of things you described at that day has not improved at the present day?—No; probably they are aggravated by the increase of population. I have not been consulted about the matter since, but at that time the condition of things, especially in the lower part of Erith, was deplorable. The works which I recommended ought certainly to have been carried out.

15,212. At that time all the sewage from the town of Erith was discharged into the river?—The whole of the drainage that was turned into the sewers went straight into the river, and sooner or later the overflow of the cesspools would have got into the river. As a matter of fact, the town was then drained into cesspools in the lower part, but all the drainage proper went straight into the river and does to-day. I saw it the other day myself.

15,213. (*Mr. Norman Bazalgette.*) How many outfalls are there now?—The same number as existed at the time of my report; three or four, I think it is.

15,214. I believe, to put it shortly, you recommended that a proper system of sewerage should be carried out, and deodorizing works put up?—Yes, I recommended, after careful consideration, that we should put up deodorizing works at Jenningtree Point, just above Erith, and then discharge the sewage into the river; that could have been done without any offence whatever.

15,215. Is the discharge of sewage at all times of the tide into a bay like that at Erith objectionable, in your view?—Certainly it is. On Monday week I was there when the sewage was being discharged, and, owing to the iron pipe of one of the outfalls having been broken, the course of it was very observable. It was not a very large quantity, but it was very objectionable. I may say that in Erith Bay at every tide there is a dead water established when it is especially objectionable; as a matter of fact, on Monday week when I was there, I could see particles of the sewage floating about, certainly not Metropolitan sewage, which was going clean past the Bay, as I ascertained when I was in a little boat, but the sewage from the sewers themselves was floating about there.

15,216. (*Sir John Coode.*) How could you be sure that the sewage you saw was not sewage from the Metropolitan sewers?—It was not fresh from the outfalls.

15,217. But what you saw was the sewage which was fresh from the outfalls?—Yes.

15,218. You judged by the appearance?—I did.

15,219. And you judged that the sewage from the Metropolitan outfalls by the time it had travelled so far would have assumed a different appearance: is that so?—I say that the sewage from the Metropolitan outfalls was going quite past, it was not coming into the bay at all. We could prove that by the floats we put in.

15,220. Are you quite sure that those were not off-shoots from the Metropolitan outfalls which got into the bay?—"To be quite sure" is a strong term to make use of, but I think I may say I am sure of it.

15,221. (*Mr. Norman Bazalgette.*) You actually saw the Erith outfalls in operation that day?—Yes, I did.

15,222. I believe you can confirm the fact that Erith is not an unhealthy place?—It is not an unhealthy place, decidedly.

15,223. If the health of Erith were not all that could be desired, would you rather attribute it to the Metropolitan outfalls or to the sanitary condition of Erith itself?—I should attribute it rather to the sanitary condition of the place itself.

15,224. With regard to the accumulation of mud which is said to have occupied Erith Bight, how do you account for that?—With regard to the accumulation of mud, I may say from observation, I cannot say from absolute measurement, that I am not aware that there is more accumulation now than there always has been, varying as it does at different states of the river in that place, and the accumulation of mud which is there arises from the fact I mentioned that certainly at every tide for a length of time, varying, say, from one and a half to three hours, the water there is in a state of rest. When I was there on Monday week, the eddy, if anything, was flowing up the bight, but, as a matter of fact, the yachts which were in Erith Bight were heading any way.

15,225. (*Prof. Williamson.*) When you said just now that there was not more accumulation than there had been for some time, I do not know which of these two things you meant, whether the actual quantity there was not greater than it was some time ago, or whether the rate of deposit was not greater?—Taking the Erith causeway and the front of Erith, I do not think there is a larger accumulation of mud than there was.

15,226. The deposit every year is not greater than it used to be?—It is being deposited and washed away, changing and changing.

15,227. In your opinion, is not there a gradual increase?—In my opinion there is not a gradual increase.

15,228. (*Sir John Coode.*) Are you aware that we have had evidence that the accumulation at Erith is greater than it was formerly, and that that increase

has led to the lengthening of the slipway, and to the necessity of cleaning the mud from the top of the slipway ?—I am not aware of that.

15,229. (*Mr. Abernethy.*) And that it was also given in evidence that certain mooring buoys, that were formerly afloat at low water, were now aground upon the mud?—That is not within my knowledge. I may also say that at the mouth of Dartford Creek, though the mud banks have shifted, there is no more accumulation than there was.

15,230. (*Sir John Coode.*) You have more familiarity with the mouth of Dartford Creek than you have with this particular causeway, have you not?—Yes, I have perhaps, although I know Erith Causeway very well.

15,231. (*Mr. Norman Bazalgette.*) I do not know whether you are a resident at Erith ?—No, I am not.

15,232. But, as a matter of fact, Messrs. Easton and Anderson's works, in which you are or were a partner, were at Erith, were they not?—Yes, but I was not there very frequently, and I am no longer there. My information is more derived from the fact that accumulations of mud upon the shore and the banks would be reported to me by the Inspector to the Commissioners of the Levels.

15,233. What would be the remedy to get rid of those accumulations, in your judgment?—That is another matter altogether; that would only be by altering the shape of the river, but there is no doubt that the mud shifts from tide to tide.

15,234. (*Sir John Coode.*) It comes and goes, you mean?—Yes, it comes and goes; there is no doubt about it, according to the state of the tide and the quantity of water coming down the river.

15,235. (*Mr. Norman Bazalgette.*) I believe you have made yourself acquainted with the evidence which has been given with regard to the chlorine experiments ?—I have read the evidence relating to the chlorine experiments. *Mr. E. Easton.* 12 June 1883.

15,236. What do you say to that?—As far as I can follow the argument, I must say it is not to my mind at all conclusive, or worth very much, for this reason that, in the first place, it must be almost impossible to take samples enough to show what the chlorine really is in the river, and then, in the next place, it comes to so fine a point that the admixture of the fresh water, which Mr. Law has mentioned, all the way down the river, would have the effect of upsetting the calculation to a very great extent. The water which has been referred to does, as a matter of fact, issue into the river the whole way from Deptford to the sea; it can be seen at a great number of places, and the quantity is very large indeed.

15,237. (*Sir John Coode.*) You say it can be seen all the way from Deptford to the sea?—Yes, I have no doubt of it; it runs out just below Deptford. The chalk is denuded in the river just below Deptford, and it is no doubt exposed in the bottom at many points between Deptford and Gravesend. The water is running out at various places, though not all the way along; at Woolwich it does not get out, but all the way along, with exceptions, there are springs issuing into the river.

15,238. Visibly?—Yes, there is a very large amount coming in at the Greenhithe marshes, and at other places; at Grays, for example.

Adjourned to to-morrow at half-past 12 o'clock.

# FORTIETH DAY.

## Wednesday, 13th June 1883.

PRESENT:

SIR JOHN COODE, MEM. INST. C.E., IN THE CHAIR.

COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
THOMAS STEVENSON, ESQ., M.D.
WILLIAM POLE, ESQ., F.R.S., *Secretary.*

Mr. EDWARD EASTON called again; further examined by Mr. NORMAN BAZALGETTE.

(*Witness.*) I think in the last few questions that were asked me by the Chairman yesterday, there was a little misunderstanding as to what I meant by there being no accumulation of mud in Erith Bight. In the former part of my evidence you will see why I show that there must have been a certain amount of mud bank in the Bight. What I referred to was the shore of the river. I was speaking of the shore of the river all the way down, and I said, if I remember rightly, that I should have heard if there had been an accumulation of mud on the foreshore of the river, from the people who have charge of the banks. You asked me a question indicating that you thought that my evidence was conflicting with the evidence of the people in Erith. What I say is, that there is no more accumulation of mud on the shore than there was——

15,239. (*Chairman.*) You are speaking of Erith Reach as a whole?—Yes, that all round Erith itself there is no accumulation of mud upon the shore. There may be a bank formed by the eddy which I explained, and there is a bank no doubt formed, because it is given in evidence; but what I referred to is the absolute shore of the river. There is no more deposit, as far as I know, upon the shore of the river, underneath what they call Erith Hard, than there was a great many years ago, certainly not more than there was in the year 1877 when I made my Report; because, as will appear by the next part of my evidence when I went down the river I walked upon that very ground.

15,240. (*Mr. Norman Bazalgette.*) I believe you have a plan showing the exact amount of increase, if any, which has taken place between the years 1862 and 1872?—That is at Dartford. Sir John asked me whether I was prepared with more particular evidence about Dartford Creek, and I had then in the room and I have now made a copy of a plan which shows the difference of the line of mud bank between 1862 and 1879, when I was making certain surveys for the improvement, the canalization in fact, of Dartford Creek. This plan (*handing in a plan*) shows the line of mud in the year 1862 when it was surveyed by the Ordnance, and the present line of it. As a matter of fact, I believe it has not changed at all in all those years. 13 June 1883.

15,241. (*Chairman.*) When you say it has not changed, do you mean as far as you could judge by appearance. This "February 1879" upon the plan, I suppose, is actual survey?—Yes, that is so.

15,242. Do I understand that what you mean by that remark is that it has not changed in all those years, between 1879 and 1883?—No; that it has not changed between the years 1862 and 1879. I mean that in the interval there is no reason for supposing there was any change. That of 1879 was a survey made for the purpose of the canalization of Dartford Creek.

15,243. It is rather a question of what it may be now?—Since 1879 I cannot tell you what it is.

15,244. (*Mr. Norman Bazalgette.*) I believe you

*Mr. E. Easton.*

13 June 1883.

went down the river with the view of making an inspection of it upon the 4th June last?—Yes, that was Monday week.

15,245. Now, will you state what you observed upon that occasion, and what you did?—I went with Mr. Chatterton and with another gentleman in the employ of the Metropolitan Board of Works, who had been in the habit of taking samples, I believe; we started from Westminster Bridge at 11 o'clock.

15,246. (*Chairman.*) What was the state of the tide then?—It was a rising tide.

15,247. Was it nearest to low water or nearest to high water?—It was nearest to high water; we timed ourselves to be at high water at Barking outfall, and therefore it was nearest to high water; we had started at 11 o'clock. There was a sample taken of the water near Westminster Bridge, from which, of course, we could perceive no smell whatever; we steamed down the river and got to Barking outfall a little after high water, a little after the sluices had been opened.

15,248. When you say "a little," do you mean a few minutes or an hour and a half?—I can give you the exact times. It was half an hour as nearly as possible after the sluices had been opened.

15,249. You were going to speak of the time the sluices were opened. You say the sluices were opened a little after high water—how long after high water were they opened?—The sluices were really opened a little before high water upon that occasion. I was there at high water.

15,250. Do you know how long they had been opened?—The man told us he thought they had been opened about half an hour. The reservoirs were perfectly full at the time they were opened, and when we saw them they were reduced 1 foot 6 inches, and that would have taken half an hour to empty. We landed and saw that the outlets were opened, and we took a sample from the outlet culvert itself.

15,251. You are speaking of the Barking outfall now, are you not?—Yes, I am. We were then in the middle of the sewage in a small boat, and, of course, it was not very pleasant. We then went across to the other side of the river to have our lunch, and to give time for a certain quantity of the sewage to go out, and we went back again and put in a float.

15,252. What was the state of the tide then?—It was then 2.46 p.m., that is to say, it would have been ebbing one hour and a half, or from that to two hours.

15,253. You may call it the first quarter ebb?—Practically it was the first quarter ebb. The float was put in, and we followed it in a small boat.

15,254. Were you in the middle of the river or near the shore?—In the middle of the sewage, close to the shore, close to the northern outfall, and we followed it down.

15,255. How far were you off the discharging point?—We were exactly over the apron, as near as we could tell, over the discharging point.

15,256. That is close to the outlet?—Yes; we were in a boat, as it were, upon the top of the outlet; the apron was then covered with water, but you could tell by the boiling up exactly where it was, and, as a matter of fact, I have no doubt that we were exactly over the outlet. The float was put in there. I have the exact time here when it was put in. I think I stated that it was at 2.46. The storage reservoir had by that time sunk down to 6 feet, that is to say, it had lost nearly half of its contents. At that time, I need not say, the smell of the sewage was very strong. There was an east wind blowing, or rather east by south, but every now and then, in fact I may say constantly, the smell even then of the chemical and guano works overpowered the smell of the sewage, so that you could not distinguish it at all.

15,257. (*Mr. Norman Bazalgette.*) Could you mention the works from which that smell proceeded? Law's Chemical Works I can specify particularly.

15,258. (*Chairman.*) An east by south wind would bring the smell from those works?—Undoubtedly. There was a sample of the water also taken there. We then followed the sewage in our small boat for about 20 minutes, until, in fact, one minute past three, or rather less than 20 minutes.

15,259. (*Mr. Lumley Smith.*) By "following the sewage" do you mean following the float?—Yes. You could see the float was in the middle of the sewage. There was no mistake about following the sewage, for it was absolutely in the middle of it.

15,260. (*Chairman.*) What was the character of the float?—It was one of the large floats, of which you have had a description, which have been used in the course of the inquiry. We followed the float until it was opposite the guano works pier, which are a little past Barking Creek, and are called the Barking Guano Works; they are past Laws' Factory, a little bit down the river below Barking Creek. We then left the float, going ourselves in the tug across to Crossness, leaving the small boat to follow the float, so that we might be sure where it was. We went, as I say, across to the Crossness outfall, and there we put in a float just opposite the place where the West India Docks are making their mud deposit upon the Erith Marshes. We put in another float there, which we also left. That float was put in at Crossness, and took a line parallel to the shore.

15,261. Was that float put in near the outfall at Crossness?—It was a little below the outfall; it was exactly opposite this mud wharf, which I speak of, of the West India Docks, which adjoins the Crossness works. The Chairman may know that the West India Dock Company have bought a small piece of land, and are bringing the mud out of the East and West India Dock in barges, and are depositing it upon the piece of land which they have acquired for the purpose.

15,262. (*Chairman.*) Is that between Johnson's Fish Manure Works and the Crossness outfall?—Yes, it is quite close to the Crossness outfall boundary.

15,263. (*Mr. Lumley Smith.*) Is it above it or below it?—Below it; between the outfall and Johnson's Works.

15,264. (*Chairman.*) Does it occupy the whole space between the south-eastern boundary of the Crossness Works and Johnson's Works?—Between that and the magazine. They have bought some more since, but I do not know the limits exactly; they are depositing the mud anyhow from the docks; and we put in the float just from the boundary, between the two, say, at the north-eastern corner of the Crossness outfall works.

15,265. Was it nearer to the centre of the river?—No; as I said before, it was in the flow of the sewage. You could see the line of demarcation as plainly as if you had drawn it upon the map; you could see it upon both sides. We then went from there across after the other float which, by this time, had got very nearly off Dagenham Jetty, upon the other side of the river, and from there we went to Erith Bight, and put in another float, which remained, as nearly as we could tell, stationary, whilst the float put in at the northern outfall had travelled half a mile, probably, beyond it.

15,266. What was the time of the tide at this period?—It was then at 20 minutes past 4, so that, if the other was a quarter ebb, this would be getting near half ebb; that float was, practically, stationary with the yachts.

15,267. Where did you put that float in; was it near the shore?—Yes, tolerably near the shore. I should think, as nearly as I could tell, about 120 yards from the shore; it was a long way within the line of demarcation of the sewage.

15,268. Do you mean up stream, or inside of Erith Causeway?—Up stream. It was put in just opposite the Upper Ballast Wharf, which I have indicated upon the plan. There a yacht, I think it was the Commodore's yacht, was facing up stream with the falling tide, while other yachts were facing in exactly the opposite direction.

15,269. Was there a strong wind?—Yes, there was a strongish wind the other way, an easterly wind.

15,270. Therefore they were wind-rode, and not tide-rode?—They were pointing in the opposite direction to the tide; they might have been wind-rode.

15,271. Or there might have been a counter-current; was there much wind?—There was not much wind; we went very near two of those yachts, disturbing them considerably with our propeller, and they nearly collided; they were very uncertain in their motion, and it took them a good deal of time to get themselves straight again, which, as I judged, would not have been the case if there had been any strong influence upon the yachts either one way or the other. As a matter of fact, I believe the float was in a sort of dead water at the time; that float was taken up again, as it was no good for any further experiment. We then went across after the Barking float, which had by that time (4.32) reached the mid-channel between Cold Harbour Point and Crayfordness; it was about mid-stream, opposite those two points.

15,272. (*Chairman.*) When you say "opposite those two points," that is a very oblique line. Do you mean about midway between those two points and mid-channel?—Yes; I meant in the line half-way between the two points; that was at 32 minutes after 4. At 4.46 the float was just in mid-channel, off Crayfordness, and there we took a sample of the water, and, as far as I could judge, there was no smell of sewage or anything else in it. The whole of the sewage from both Barking and Crossness had by that time, upon this particular day, disappeared entirely, and I do not think you could have recognised any trace of it by the senses. At 5.5 the Barking float was in mid-channel at the top of Long Reach, looking fairly down Long Reach, and there we took it up. As we were at Crayfordness we took a sample of the sand that three barges were dredging for. These three barges were exactly opposite Crayfordness.

15,273. (*Mr. Norman Bazalgette.*) What was the sand like?—I have not a sample of that sand with me, but it was a bright sand, covered on the top with a very small thickness of black material or mud.

15,274. I presume those men who were dredging were dredging for profit?—I presume they were. I know nothing about that.

15,275. (*Chairman.*) Was that near the shore?—It was near the southern shore, at Crayfordness.

15,275. Did you ask them for what purpose they were dredging the sand?—I do not know that we did, the sand was very much like that (*producing a sample*). It was pretty evident that the sand was being dredged for building purposes, it was sand that could be used for cement work or anything of the kind when it was washed.

15,277. (*Mr. Norman Bazalgette.*) Did you smell it at all?—There was not the slightest smell in it that I could detect when it was brought out.

15,278. (*Chairman.*) Was it a bag and spoon dredge?—Yes, that was a bag and spoon dredge.

15,279. Did you detect any smell when the spoon came out?—No.

15,280. (*Mr. Norman Bazalgette.*) Were those three men the only men you saw dredging for sand when you were down the river upon that occasion?—No, we took another sample when we were up at Cubitt Town afterwards; men at this point were dredging for sand.

15,281. And at other points you saw other men dredging for sand?—At two or three other points, but I will not specify the other points, except the one at Cubitt Town. We then went back to Erith and visited one of the Erith outfalls which I had not seen since I visited it in 1877 for my report; that was the one where the iron pipe was broken, and which was discharging sewage at about half tide upon the shore. We then went to Erith Causeway and landed, and took a sample of mud, which after being dried, produced that sort of stuff (*handing in a sample*). I have no doubt you will have this given more accurately, but this is an engineer's way of finding out what was in the mud; there is about from 40 to 50 per cent. as nearly as we could tell at a rough estimate, of that sand in the mud by the side of Erith Causeway.

15,282. (*Chairman.*) This sand has been washed, has it not?—Yes, it has been washed, and that is the product.

15,283. This is the residuum of a much larger quantity?—This is the residuum of about double that quantity in bulk; and of the rest a very considerable proportion you could see was coal dust and pieces of brick and different things. Having taken that sample of mud off Erith Causeway, I might say that we pushed a pole into the mud, and as far as I could judge, and I think I have a pretty acute smell, I could not detect any offensive smell from the mud on the pole, and I think that sample shows why that was.

15,284. Could you give us the position with regard to the Causeway where you did push this pole down?—It was in two or three places all the way along. It was then getting to near low water, it was at 5.45, and it must therefore have been near low water.

15,285. But at what point with regard to Erith Pier?—It was on the Causeway.

15,286. Is that the same thing as the pier?—No it is quite a different thing, the pier is there (*pointing to the plan*) and the iron pipe which has been spoken of as being broken, which is a small affair, is there (*The same was pointed out*).

15,287. Then Erith Causeway is near the "Crown"?—Yes, it is close to another outfall of the sewage, the Causeway runs out to low water. I think it has been given in evidence that it had to be lengthened at the lower part of it, but that is not the higher part of it, it is the lower part which they say has been raised. We passed down upon that and pushed the pole down into the mud. If I remember rightly, it was upon the western side towards the up side of the Causeway, but we tried it at several places walking along the Causeway from low water mark up to the edge of the shore, and a sample was taken as nearly as possible, I should say, 30 feet from the end of the Causeway, from the mud.

15,288. Have those samples been analysed?—I believe the chemists are analysing them. You will have reports upon them.

15,289. Unless they have been analysed, I do not know whether it is necessary to go into all these details?—They have been analysed.

(*Mr. Norman Bazalgette.*) The analysis will be put in by-and-bye.

(*Witness.*) They were very carefully taken and brought home for the purpose of analysis, and what I am giving you now is only a small portion of the sample to show that there is sand in the stuff. Now continuing my voyage, at the point at which I left it, near the Isle of Dogs, as we came opposite Cubitt Town there were some other men dredging for sand, and this (*handing in a bottle*) is a sample of what they got, which is a coarser description of sand. This was on the east bend of the river there opposite Cubitt Town Pier, very nearly opposite the Thames Soap Works and the Greenwich Candle Works. I have marked that sample "C. T."

15,290. (*Chairman.*) What proportion does this bear to the bulk of the sample from which it was taken?—I should think that that is about a twelfth or a fifteenth part of the sample; it was taken in a spoon and put into a jar, and then brought up and given to the chemists, and that was washed out for me to see what the sand was. I think you will find from the chemist that that would be about a twelfth or a fifteenth part of the total sample.

15,291. (*Mr. Norman Bazalgette.*) Did you notice the smells from the factories when you were there on Monday week?—Yes, you could not help noticing the smells from the factories, particularly of the fish manure factory on the opposite side of the river to Erith, you could smell that of course very strongly. It was an unfavourable day for smelling because there was a strong breeze, but you smelt it in a concentrated form I expect. But I know, as a fact, that

*Mr. E. Easton.*

13 June 1883.

you can smell all those smells at Erith and at other parts very distinctly; some of the cement works are especially offensive.

15,292. In your judgment, what is the effect of letting out the sewage at high water?—I think I have said already that the way in which the sewage is let out at Barking, is the best way that could possibly be conceived. High water, I need not explain to the Commission, takes the sewage, as we saw, straight away more or less in accordance with the time of the tide; at any rate it takes it straight down the river.

15,293. (*Chairman.*) You do not mean to tell us that the letting out of the sewage before high water, as you described just now, is the best mode of procedure?—I mean to say as it ought to have been let out, as the regulation is to let it out.

15,294. You would not advocate letting the sewage out before high water, I should think?—There might be certain times at which you would let it out before high water. It would depend very much upon the tide.

15,295. (*Mr. Norman Bazalgette.*) Respecting that answer you gave just now, I want to ask you this,—whether the percentage of the clean sand in the Cubitt Town sample does not amount to about 90 per cent. of the whole sample?—I cannot say that of my own knowledge, but you will hear more of that from the chemists.

15,296. In saying it was a fifteenth part, you did not mean to say that was the percentage of the clean sand?—No. The Chairman asked me what was the proportion of the sample to the whole sample, and I said that it was about a fifteenth part.

15,297. Assuming the sewage discharged wholly upon the ebb, is it in your judgment possible for any deposit to be made of the sewage in Erith Bight or any other part of the river?—I will not say "in any other part of the river," but I cannot see how the sewage from the metropolitan outfalls could be deposited in Erith Bight.

15,298. (*Chairman.*) Did not you say there was a counter current of slack water in Erith Bight, and might not that be the means of depositing the sewage there?—Not the sewage as it comes out of the outfall. What I mean is this, that the sewage, after it has been mixed up with the general water of the Thames by going down the river, may then come back mixed with water into Erith Bight; but that is a different thing. The sewage itself as it comes out of the two outfalls cannot go into Erith Bight.

15,299. I suppose no one ever imagined that sewage would be deposited in Erith Bight in a form as concentrated as that in which it left the outfall; but the question is whether a considerable portion of the sewage in the form in which it reaches Erith does not get deposited upon the beach?—That is not so. I think I am right in saying I do not think it could.

15,300. (*Professor Williamson.*) You say that sewage could not be deposited; but, after all, I cannot imagine that it is a question of the deposit of sewage. No one could imagine that sewage, which is a mixture of liquid and solid substances could be deposited. The only question is whether certain solid substances suspended in the sewage could, when the mixture was moving less rapidly, be deposited in the slack water?—You mean, I presume, by solids certain flocument animal or vegetable matters. I do not see how that could be from the sewage. I conceive that the sewage must be so mixed with the water that, in the shape in which you put it, I cannot see how that can possibly be deposited from the metropolitan sewers, and if there is anything of the kind in the samples, it must come from local causes.

15,301. That the deposit of animal matter at Erith must arise from the Erith drainage?—Yes, practically.

15,302. (*Mr. Norman Bazalgette.*) I think you told us when you began your evidence that, in your judgment, the position of the outfalls had been well selected?—I said so at the beginning of my evidence.

15,303. Do you think, having regard to the conditions and circumstances as they exist at the present time, that the present position of the outfalls could be improved?—That is a large question. I think that is going into the other part of the subject.

(*Chairman.*) The Commission have decided not to go into that at the present stage of our inquiry.

(*Witness.*) If you will put it between the two points that Lord Bramwell mentioned, Greenwich and Gravesend, I would say it certainly could not be improved upon.

15,304. (*Colonel Ewart.*) Did you look at the sewage in the tanks before it was discharged?—Yes, certainly. I went over the discharging culvert which came from the tanks. You cannot very well look into the tanks, but a sample was taken from the discharging culvert as it came from the tanks themselves.

15,305. As I understand, you did not see it actually flowing into the water? It was let in and mixed with the water below you?—It was all absolute sewage.

15,306. What was the appearance of it? Was there an appearance of solid matter, or was it very much diluted?—I know it could not be very highly diluted. There was a certain amount of solid, there was a good deal of debris, wood and straws and that sort of thing, and some brownish solids, which, no doubt, were excrement, as it came out. There was a very marked line where the sewage ceased. You could see immediately by the stuff that was flowing down the river which came out of the sewage, straws and pieces of wood, where the sewage line was.

15,307. You saw a clearly defined line, I suppose, which the sewage made?—Yes, a clearly defined line.

15,308. Could you trace that line far?—Yes, you could trace it as far as we followed it, certainly, and then it lost itself; and the same with the Crossness discharge.

15,309. You saw the Crossness outfall distinctly discharging before it mixed with the water?—Yes. We had not arrived at Crossness until, I think, two hours or more after it began to discharge, but still there was a distinct line travelling down parallel to the river, and then striking towards the shore, and joining the other line which came from Barking, and this in the face of a strongish easterly wind blowing.

Cross-examined by Mr. Beaumont Morice.

15,310. Do I understand you to say that the mud has not increased in Erith Bight recently?—No. I explained, when I came into the room first to-day, that there was a misapprehension about that. I do not know what the state of the mud is in Erith Bight itself, what I say is that the mud has not increased upon the shore in Erith.

15,311. What part of the shore are you speaking of?—I am speaking of the whole of the shore more or less, but I can speak especially of the shore below the outfall at the middle of those three sewers by the mill.

15,312. When did you last have an opportunity of seeing this mud?—The other day. Monday week.

15,313. Have you noticed it often during the last two years?—No. The last opportunity I had before that of making an examination which would be worth recording was when I was making a report about the sewage in 1878, I think it was.

15,314. I may take it that you cannot speak decidedly as to how much it has increased during the last two or three years?—I do not know what it increased, if it did increase, in the interval. I say the mud at the present time is no more than it was in 1879 on the shore.

15,315. Do you know anything about it further up the river than the mill which you mentioned? Do you know the Church Hole?—No, I do not. I did not go there.

15,316. You do not know that part?—No, not for this purpose. I know every part of the bank generally.

15,317. As far as the mud is concerned, you cannot tell whether that mud has increased in recent years or altered in quality ?—I cannot. I walked upon this hard for this purpose, the same as I did before.

15,318. (*Chairman.*) Is the whole of the beach in such a condition that you can walk upon it ?—Yes, you can walk upon it at that part, and you would not mud your shoes.

15,319. Would you say that it is all hard from low water upwards ?—No, certainly not, because we took our samples of the mud below.

15,320. Near the low-water edge ? — Yes, and further up.

15,321. What I want to know is, where upon the beach is this particular hard ?—It is just by the head of the causeway, close to the shore.

15,322. About how far did it extend as between high and low water—what proportion would it bear ? —It would be, perhaps, a quarter of the way to low water it is a wharf, in fact.

15,323. What is the extent of the breadth of the hard ?—It is not many feet.

15,324. What is the extent of the breadth of the mud ?—It is very considerable. I should think 150 feet.

15,325. (*Mr. Beaumont Morice.*) You talk about the beach, is there any beach there at all, in the proper sense of the term ?—I do not think I called it a beach.

(*Chairman.*) I think I said beach, and Mr. Easton spoke of the hard.

15,326. (*Mr. Beaumont Morice.*) As a matter of fact there is no beach ?—Certainly not.

15,327. When you say "the shore," I should like to know exactly what you mean by the term "shore"? —What I mean is the banks of the river, a sloping sea-wall, which slopes out a certain distance.

15,328. (*Chairman.*) You do not mean the foreshore ?—I do not mean the saltings.

15,329. But the foreshore is between the edge of the bank which you protect and the water ?—No, that is not so.

15,330. (*Mr. Beaumont Morice.*) At the part you mention, is there not a steep slope going down under the foreshore ?—Yes, there is ; it is a wall ; it is nearly perpendicular.

15,331. From that wall is not there a hard, in the strict sense of the term, that is to say, a built hard, extending out into the river ?—I think not ; not as far as I remember.

15,332. Is not this the hard that you walked down ? —I went on to the hard bottom, but I do not know how that was made.

15,333. What time of the tide was it ?—It was getting towards low water ; at all events, there was get mud on it.

15,334. How far down did you go upon the hard ; did you go right to the end ?—We went along the causeway from the boat, right up to the hard ; we traversed the whole ; we did not walk upon the mud ; we walked upon the hard, and then got off to see the outlet of the sewers.

15,335. Was there no mud upon the causeway ?— Certainly not. When you say "*no mud*," I do not know quite what you mean by the term. There were the remains of what the river itself would deposit ; there was not a quarter of an inch thick in any part ; I should call it no mud ; there was not what you would call a deposit of mud on the hard ; there was merely the deposit left by the river.

15,336. Did you notice what that was like ?—No ; it was not enough to pay any attention to ; it did not draw one's attention to it all.

15,337. Will you tell me the exact spot where you put this pole down ?—We put the pole down in three or four places along the causeway.

15,338. What depth of mud did you get ?—We put it down four or five feet.

15,339. No more than that ?—No, we did not push it down further ; I do not think the pole was long enough.

15,340. Did you put it down upon both sides of the causeway ?—Yes, we put it down on both sides of the causeway ; but I think it was generally put upon the shore side.

15,341. (*Chairman.*) I understand you to say that the pole was not long enough, and that was the reason you did not push it in further ?—There might have been any amount of mud below ; we did not go to the bottom of it, as far as I know.

15,342. (*Mr. Beaumont Morice.*) That was the mud you took samples of, was it not ?—Yes, we took samples of it ; two samples, I think, but one at all events ; that was the mud out of which the sand, in the bottle before the Commission, came.

15,343. I understood you to say there was no smell from that ?—There was a muddy smell from the pole, but no smell of sewage ; merely what you would expect to find if you poked it into a pond.

15,344. May I infer from that that there was no sewage there ?—No, I do not infer that at all. I infer that there was nothing offensive in the mud at that time.

15,345. Whether sewage or anything else ?—Whatever it came from, it was not a bank of sewage.

15,346. You referred to the drainage of Erith, which you made a report upon, and in that report you state that the sewage only referred to Erith proper ; do you know the extent to which houses in Erith are drained by sewage pipes ?—I have before me the way in which every house in Erith is drained, and not only in Erith, but in the whole district. I could give you, in detail, how every single cottage was drained, I think.

15,347. Is it your opinion that the sewage of Erith causes the nuisance of which the inhabitants complain ? —I do not know what the nuisance is to which you refer.

15,348. That the nuisance arising from the sewage outfall or drain of Erith causes the nuisance of which the inhabitants complain ?—I am obliged to repeat that I really do not know what nuisance the inhabitants complain of ; if they complain of smells, I can refer them to a good many stinks.

15,349. May I ask you if the outfall at Erith would be sufficient to produce a nuisance offensive to Erith ? —Yes, I think it might very readily.

15,350. (*Chairman.*) I understand you to say that you do not think it does. If I understand your view accurately, there is no nuisance at all there, whether from the metropolitan sewage or from the Erith sewage ; that is the impression your evidence has left upon my mind up to this moment ?—I think I said I saw some evidence of stuff on the day I was there floating about.

15,351. But not enough to create a nuisance ?—No, not upon the day when I saw it.

15,352. Then your view is that there is no nuisance ? —I do not think there is a nuisance in the river arising from sewage at all.

15,353. Whether from the metropolitan or the Erith sewage ?—No. I do not think you could smell Erith sewage quâ sewage. I had, perhaps, misunderstood the question of the learned counsel ; but I say that I do not think there is any nuisance coming from the sewage, and that is the reason why I asked what is the nuisance they complain of. The nuisance that I complain of in Erith is that there is not sufficient drainage ; that is all I complain of.

15,354. (*Mr. Beaumont Morice.*) You have mentioned about the factories ; can you distinguish between the smells of those factories ?—Some of them certainly I can. I am obliged to repeat my old friend the Fish Manure Factory.

15,355. Can you distinguish between the smells from factories and the smells from sewage ?—Sometimes you can. When we were in the middle of the sewage we frequently smelt the sewage alone, until, as I said in my evidence, the smell from Law's Works overpowered the smell of the sewage.

15,356. May I take it, speaking generally, that you can tell a factory smell from a sewage smell ?—I do

*Mr. E. Easton.*

13 June 1883.

not think there is any doubt about it. When once you have smelt the sewage smell and the factory smell you will be in no doubt about it.

15,357. And the people living in the neighbourhood of the various smells can tell it too?—I doubt very much, when other smells are mixed up with it, whether you could smell one more than another; but the smell of the sewage is certainly a distinct smell.

Cross-examined by Mr. Lumley Smith.

15,358. You told us yesterday that you had seen this stuff floating about the other day; is that the same occasion that you were speaking of when you spoke to-day of the 4th of June?—If you are referring to the small particles I said I saw floating about, it is the same occasion. I have seen it upon an occasion years ago, but this is the occasion I am speaking of.

15,359. With regard to the floats; you put in three floats, I understand?—I did.

15,360. One at Barking, one at Crossness, and one at Erith Bight?—Yes.

15,361. Those were the only three you put in?—Those were the only three.

15,362. With regard to the samples; those samples that you took, as I understand, were submitted to the chemists; is that so?—They were all sent to the chemists of the Metropolitan Board of Works.

15,363. Are they samples of water as well as samples of mud?—There are samples of water; we took a number of samples, and there were samples of water as well as samples of mud and samples of sand.

15,364. Did you label them in the boat?—Yes.

15,365. Do the labels show exactly where they were taken?—Exactly, and the times, and the temperature; we took them all.

15,366. (*Chairman.*) And the depth below the surface?—Yes, in every case.

15,367. Were they taken at one uniform depth, or at different depths at the same spot?—We took one sample at each spot, at a depth generally of two feet beneath the surface in each case. I am speaking now only of the water; but there was only one sample taken at each part, and not at different depths at the same spot.

15,368. (*Mr. Lumley Smith.*) With regard to the samples that you have brought here, the mud has been washed, I understand, and then baked?—One of them is a sample of mud.

15,369. But the process has been the same?—Yes.

15,370. First of all it has been washed, and then it has been baked or dried?—The water has been evaporated off it, and that is the dry residue; but the mud, in each case, has been washed off, you may say.

15,371. You spoke of coal dust; coal dust would remain, would it not, if it were here?—That was washed off; but there was very little of anything upon the top of that last sample you took up, marked C.T.

15,372. Now, with regard to the line of mud; this is the plan that you have handed in; that was made for what purpose?—That is the plan which was made for the purpose of my making a report for the canalisation of Dartford Creek, about the year 1879.

15,373. Which of those lines represents the line of mud in the year 1879, and which in the previous year?—The black is the line in 1879 and the blue one is taken from the ordnance map which was surveyed in the years 1863 to 1866.

15,374. Your map does not show which is which, does it?—Yes; you will find the blue line which is dotted, that shows what it was upon the ordnance survey.

15,375. That does not show much variation?—No, it is exactly the same.

15,376. Was not the year 1879 a very wet year; do you remember?—I do not remember.

15,377. Were not the years 1863 to 1865 very dry years?—I do not remember.

15,378. If you are comparing a dry year with a wet year, that will not be a fair comparison, because there is a great deal more water comes down the rivers Dart and Darenth in a wet than in a dry year?—No, not very much more, because it is one of the chalk streams and it is a tidal river as well; the quantity of water issuing from Dartford Creek depends a good deal more upon the tide than it does upon the quantity of upland water.

15,379. But it is only tidal just up at the mouth, is it?—It runs up inland as far as Dartford.

15,380. I did not quite understand when you told us that your third float that was put in at Erith Bight, and was stationary, was within the line of demarcation of the sewage; is that the sewage from the outfall?—From the Crossness outfall.

15,381. When you say "within the line of demarcation of the sewage," do you mean within the sewage?—No, the sewage was out far beyond it.

15,382. By "within" you mean not in the sewage?—In shore of it.

Re-examined by Mr. Norman Bazalgette.

15,383. The Thames water, I believe, contains a certain amount of suspended matter, part of which is of natural origin and part, no doubt, due to whatever suspended matter is contained in the sewage discharged into the river?—Certainly, and to the solid matter which has been washed from the bank.

15,384. You pointed out that in slack places the tendency is for this suspended matter to deposit?—Certainly.

15,385. And Erith Bight is one of those places?—It is.

15,386. Therefore, you would expect to find in Erith Bight a certain proportion of deposit?—What I should expect is that all down the river one would find more or less of the natural deposit of the river mud, whatever it consists of; and I think the samples which have been taken will show that most of the deposits are natural river mud; they are only a question of degree. Where the current is slack, you will find fine stuff like that E.C. sample, which is the deposit from gravel in the upper reaches of the river. Where it is running more freely, as it does at Cubitt Town, you will find it coarser, like the C.T. sample; and in other places, where the current is quicker, you will find it approaches sharp sand and gravel. But in every case you will find the same constituents as you see there, and upon the top, probably, some traces of sewage.

15,387. Now you told us that you put a pole in at Erith about five or six feet down?—Yes, we did.

15,388. And on withdrawing it, did you pass it across the nose?—Yes.

15,389. Was there no smell?—There was nothing but the ordinary riverine smell.

15,390. As far as that went, you would say there was no smell of sewage in the mud?—I could detect nothing.

15,391. As far as the smell of sewage went?—Yes.

15,392. Do you know the channel by Beadel's Wharf?—I do.

15,393. Is that in close proximity to the main outfall sewers?—Yes.

15,394. Would you be surprised if the men who work in that channel come here and complain of the nuisance, having regard to its proximity to the No. 1 outfall sewer at Erith?—No. At the time I was there the No. 1 sewer pipe was broken, and was discharging on the shore at half-tide, but I do not think that would be injurious to health, although it would be unpleasant.

15,395. Now, was there an easterly wind blowing when you put in the floats?—Yes, there was.

15,396. The tendency of an easterly wind would be to make the float set in towards Erith?—That wind would have an effect upon the water, but not upon the floats. The float followed in the stream of the sewage as plainly as possible.

15,397. Did you not tell us that one float was put in near the Crossness sewage outfall?—I have already stated that we lost it in the line of mid-channel.

*Mr. Lumley Smith* stated that there had been no cross-examination upon this point.

Examined by the COMMISSION.

15,398. (*Colonel Ewart.*) I think you mentioned that you had prepared a project for the drainage of Erith?—I have, certainly.

15,399. Where did you propose to discharge the sewage?—I was proposing to deodorise the sewage, and discharge it just above Jenningtree Point.

15,400. Did you propose to deodorise it with chemicals?—Yes, by the lime process.

15,401. Why did you propose to use the chemical process?—In order to comply with the Act of Parliament.

15,402. You proposed to deodorize the sewage before it went into the river?—It was evidently desirable.

The witness withdrew.

Mr. ROBERT GORDON TATHAM called in; examined by Mr. MICHAEL.

15,403. You are a member of the Royal College of Surgeons of England, and a licentiate of Apothecaries Hall?—I am.

15,404. I believe you have been, for over 20 years, surgeon to the Honourable Trinity Corporation?—I have been so for a considerably longer time than that, for I was in partnership with my father some years before that.

15,405. Have you had considerable experience of the river?—I have lived near it all my life.

15,406. Where do you reside now?—At Poplar.

15,407. Has the Trinity Corporation a wharf at Bow Creek, where the River Lea joins the Thames?—Yes, they have.

15,408. I think the wharf is at the actual junction, and faces eastward upon the Lea, and southward upon the Thames?—Yes.

15,409. How are the Trinity men of this district employed?—They are employed on board the light-vessels, at lighthouses in the London district, and on board the steamers.

15,410. At night where are they?—There is a crew that belongs to each vessel, and of those men; a portion of them are down on board for two months, and up at the wharf for one month; each month they are relieved. They sleep at home.

15,411. May I say that all day long they are more or less upon the river?—Those that are at the wharf are down there all day.

15,412. And the other portion, where are they?—They are out at sea.

15,413. Where do they sleep at night?—About in the neighbourhood, in their own houses; they live about in the neighbourhood of Poplar and Blackwall.

15,414. We have adopted the term "riverine" here; may their residences be said to be riverine, or somewhere in contiguity to the river?—I daresay the majority of them live within half a mile of the river.

15,415. How many men are so employed?—There are about 200 who are there; it does not come under me, because I only attend them medically, but I suppose there must be about half of them at the wharf at one time.

15,416. (*Chairman.*) Do you attend the families as well?—Yes, I do attend a good many of them; not on account of the Trinity Corporation, but in general practice.

15,417. (*Mr. Michael.*) What is the health, generally, of the men employed?—They have very good average health.

15,418. Have you been able to attribute any illness that they have had to any emanation from the river?—I have not.

15,419. Have zymotic diseases generally prevailed amongst them?—No.

15,420. (*Chairman.*) Have they ever suffered at all from zymotic diseases?—No, I do not know that they have.

15,421. (*Mr. Michael.*) Could you mention one case of scarlet fever which occurred in a man's family?—That was the Superintendent's family, who live on the wharf.

15,422. Were you able to trace the outbreak in that case of scarlet fever in the family?—The predisposing cause was the defective drainage of the house itself.

15,423. That house has been since rebuilt, has it not?—Yes, they have pulled down the old house, and built another.

15,424. (*Chairman.*) Did you satisfy yourself, personally, that that was the case, that it was owing to the defective drainage of the house?—Yes, perfectly. None of the men on the wharf were ill. The children were going to school, and perhaps they took the disease at school, but they were predisposed to it by the bad state of the drains of the house in which they lived. I examined the house, and reported on it to the Corporation.

15,425. (*Mr. Michael.*) Is there a hulk stationed off the wharf?—Yes.

15,426. How many men sleep there?—Two men.

15,427. Have you had any zymotic disease there?—No.

15,428. (*Chairman.*) Are they always the same men, or do they change?—They are always the same.

15,429. (*Mr. Michael.*) I suppose there could not be any case of zymotic disease among your men without your knowing it?—No, because I attend them all.

15,430. Are there any Trinity steamers lying off the wharf?—Yes, there are constantly.

15,431. And are the men going constantly in boats to and from the steamers?—Yes, they all belong to the same service, so they all are called Trinity men.

15,432. Have you heard any complaints for the last two or three years of the bad state of the river?—Not for the last two or three years; but two or three years ago they used to complain sometimes.

15,433. At that time was there any increase of sickness?—No.

15,434. (*Chairman.*) Did you consider at the time that the complaints were well founded?—Sometimes in the hot weather I have noticed it, but I have not noticed it for the last two or three years.

15,435. (*Professor Williamson.*) What have you noticed?—I have noticed a little bad smell from the river.

15,436. (*Mr. Michael.*) Would that be upon the river itself?—It would be upon the river itself or upon the bank of the river.

15,437. Do you go much upon the river yourself for any purpose?—Occasionally I do.

15,438. (*Dr. Stevenson.*) At what part of the river would you perceive the smell?—It would be down towards Blackwall.

15,439. (*Mr. Michael.*) I think you are also surgeon, are you not, to the East and West India Dock Company?—I am.

15,440. Have you under your charge the men employed upon those docks?—The permanent labourers, foremen, &c.; all those who are residing in my district.

*Mr. R. G. Tatham.*

13 June 1883.

15,441. To what number?—Between 700 and 800.

15,442. Is the water from the river let into those docks every tide?—The gates are opened at every tide.

15,443. And are the men constantly employed more or less on the water or by the side of the water?—Yes, they work all round the dock, from eight in the morning until, on the average, I suppose about five o'clock; sometimes they leave earlier and sometimes later; many of them are employed all night at the tide time.

15,444. Has there been any prevalence of zymotic disease amongst those men?—No, there has not.

15,445. I understand you to say in your proof that there have been 31 deaths in the six years; were any of those from zymotic diseases?—Not one of them.

15,446. (*Chairman.*) Speaking broadly, what number of men is, on the average, employed daily upon the Trinity Wharf?—I have hardly any means of judging of that.

15,447. Do you know how many sleep there; you told us the superintendent did?—The superintendent and his family, and the storekeeper and his family; his family are grown up.

15,448. (*Dr. Stevenson.*) If any cases occurred of zymotic diseases among those men would you be likely to meet with them, or would they be removed to a hospital without your knowledge?—No, they would not be removed to a hospital unless I ordered them to go.

15,449. (*Professor Williamson.*) Then would you kindly explain something that was stated just now. Am I correct in understanding that 31 deaths in six years took place among the 200 men, the average number employed?—No, the average number employed is between 700 and 800 in the dock belonging to the Provident Society.

15,450. (*Mr. Michael.*) I was speaking then of the men employed in the East and West India Docks; were there 31 deaths in six years amongst 700 and 800 men?—Yes; that is an average of $5\frac{1}{6}$th per annum; but no doubt there would be two or three more deaths, because there would be some accidents which would be taken to the hospital and the men would die in hospital; but those 31 would come under my charge.

15,451. I presume any case of disease, putting accidents out of the category, would come under your knowledge; you would be sent for as the surgeon in attendance?—Yes; a few of the men might perhaps belong to a club and go somewhere else, but very few of them.

15,452. Do you reside yourself anywhere near the river?—Yes, I do, and I have done so all my life.

15,453. You do not seem to have suffered very much from any bad emanation of the river if I may judge from your appearance?—No. I was born close by where I am now, and have lived there all my life.

15,454. (*Chairman.*) And about how far from the river as the crow flies?—About a quarter of a mile.

15,455. (*Mr. Michael.*) Have you made any observation of the condition of the mud at the side of the river?—Yes, I have.

15,456. What has been the condition of it in your experience for the last few years; has it increased, or has there been denudation?—There has been denudation. When I first remember it as a boy, all round the Isle of Dogs and opposite at East Greenwich, all along the shore it used to be mud with reeds and rushes growing the same as in country rivers; but since the introduction of small tugs principally, the mud has gradually washed away, until now in most parts it is washed clean to the gravel.

15,457. (*Chairman.*) You attribute that change to the agitation caused by the tug steamers, do you?—Yes, I do.

15,458. (*Mr. Michael.*) Do you think that in consequence of that there has been any increase of matter in suspension in the water?—Yes, most certainly; but the river has cleared itself very much in the last two or three years; that is to say, the water is much clearer now than it was two or three years ago.

15,459. As a general result, may I say that the denudation has swept away the mud and left clean gravel in its place, and that the condition of the water itself in your experience has improved?—Yes, it has; and I have heard the same remark from others about the water-side.

15,460. (*Dr. Stevenson.*) Can you account for that clearing of the river in the last two or three years?—A few years ago, when the tugs came into use, the mud was much mixed with sewage deposited by the tide, and when the denudation began, and until it was washed away, the smell was very bad. Now, however, it is principally earth in suspension, and does not smell as it did before.

Cross-examined by Mr. Lumley Smith.

15,461. These Trinity men are men who are employed some of them in lighthouses, are they not?—Yes.

15,462. And some of them in going out and looking after the buoys and other lights at sea?—Yes, that is all their duty.

15,463. A man is two months in a light-ship at sea, and the other month he comes back and stays at home?—Yes.

15,464. Two months is as much as a man can stand in a lighthouse, so he comes and stays a month at home?—No, the lighthouse keepers are men who are changed every month.

15,465. But the greater part of the time the men of the light-ships are in good fresh air at sea?—Yes, they are.

15,466. And during the time they are not at work, they are hanging about the wharf?—Yes, that is so.

15,467. Have they anything to do, or is it merely staying at their homes, or have they to report themselves at the wharf?—They are down at the wharf the whole day.

15,468. (*Chairman.*) There is duty ashore and duty afloat to give the men the necessary amount of change?—Yes, exactly.

15,469. (*Mr. Lumley Smith.*) What have they to do at the wharf?—They have to send stores from there all round the coast, to keep the vessels supplied with oil, and all sorts of things; and, moreover, frequently some of the men have to go away in steamers.

15,470. They are men in good health ordinarily, are they not?—They have to come to me to be examined before they are taken on in the service.

15,471. They are not taken into the service before you have certified that they are fit for the service?—They are not.

15,472. And they are men who spend two-thirds of their time in good fresh air out at sea?—Yes, they are.

15,473. And then, in case of illness, do you attend the men at their homes?—Yes, I do.

15,474. Are they men who belong to clubs at all?—No doubt some of them do.

15,475. And among the labourers a good many belong to clubs, do they not; that is to say, among the East and West India Dock labourers?—They have a club belonging to the dock itself, a provident society, and they all belong to that; the whole of these men that I speak of belong to that society.

15,476. Have they any medical attendant attached to that club?—Yes, I am the medical attendant of the club.

15,477. The labourers, I suppose, are strong active

men?—Yes, and they have to come to me to be examined.

15,478. They have to come to you to be examined and certified before they are taken on?—Yes.

15,479. Now, with regard to the illness that does take place, do you keep any record of it, or are you speaking from memory as to the cases of illness?—I make no report, but I put down in my diary when the men apply to me what the diseases are that they are suffering from.

15,480. But the exact catalogue of all the diseases that you have attended would take a long time to make out, would it not?—Yes, it would.

15,481. Now you spoke of rushes having been seen upon the banks of the Thames; what period were you speaking of then?—That would be a long time ago. I was speaking of 40 years ago.

15,482. And they have disappeared, have they not?—Entirely.

15,483. Did they go before the mud; because what I was going to suggest to you was that the river was very bad in the neighbourhood of Blackwall?—Yes.

15,484. We have heard that sewage destroys vegetation sometimes; may it not have been that the sewage was so bad in the London neighbourhood and extending to Blackwall that it destroyed the rushes?—I could give no opinion upon that, but I can say that down to 1849 up the River Lea there were reeds and rushes growing, because I remember when I was a student at the time I went botanising along there, and I went along the banks of the Lea, and I took home 50 specimens of plants growing upon the banks of the Lea.

*Mr. R. G. Tatham.*

13 June 1883.

15,485. (*Chairman.*) Within what distance from the Thames?—Just a little above this Trinity Wharf.

15,486. You do not mean far up the Lea, but in the immediate neighbourhood of the Thames?—In the immediate neighbourhood of the Thames.

15,487. (*Mr. Lumley Smith.*) Do you say you could perceive the sewage in the river as far down as the Lea, before the outfalls were open?—No, I did not say that.

15,488. You have been asked about the state of the river and the reeds before the outfalls were opened?—I would rather not give an opinion as to what caused the death of the plants.

15,489. But I will ask you, was the river bad from the London sewage before the outfalls were opened; am I right in my assumption?—Yes, I think so.

15,490. You think that at that point you could perceive the effect of London sewage?—I have noticed it in crossing in steamers to Greenwich.

Cross-examined by Mr. Beaumont Morice.

15,491. I will ask you one question about the mud; have you noticed whether the mud near the entrance to the docks has increased in the last few years?—That I could hardly say; it would be more by dredging that they would find that out.

15,492. As a fact you have not noticed it?—No. I have noticed more what is to be seen between high and low tides.

15,493. Has there been any alteration in the quantity or quality of the mud?—The mud has been washed away down to the gravel, leaving many places clear, where, when I was a boy, it was mud up to the knees for aught I know, but where you could now walk along as you could upon the beach by the sea-side.

15,494. Do you find any smell from the mud that there is there?—I do not notice any smell, and I have not heard any complaints lately from the men. About two or three years ago there was a good deal of complaint; the men noticed it very much at the time of letting the water out of the dock when it stirred up the mud that was in the lock; but since then I have not found it so. I have heard the dock officials say the same thing.

15,495. We have it in evidence from Captain Hussey, who was the principal dock-master at the docks, that he finds what he calls a great stench; do you notice anything of the kind from the mud?—I have not noticed it, but that would be at the time I mention. Those locks are enclosed with gates at each end, and if they want to make a level they would open the sluices and the water would come through and stir up the mud; and it is quite likely that at some time of the tide they would smell it if they were on the spot, whereas I might go down an hour afterwards and not notice it.

15,496. (*Colonel Ewart.*) I should like to ask you about the men working near the river?—To which of the two classes of men I attend are you referring?

15,497. To all of them; do they go to work before sunrise?—No, they do not go to work so early as that.

15,498. Do they go shortly after sunrise?—Yes.

15,499. And they leave before or at sunset?—Yes, they work from eight o'clock in the morning in the summer and from nine in the winter to what is supposed to be four in the afternoon, but it is frequently, as likely as not, six o'clock before they get away. Now they work at such high pressure that they frequently work at night.

15,500. In point of fact, between sunset and sunrise the men are living away from the river, are they not?—Yes, excepting the gate-men who attend at the gates taking in the vessels; they attend there every tide, whether it is night or day; they are down there for about four hours each tide.

Re-examined by Mr. Michael.

15,501. Could you tell the Commission about the distance, on an average, those men live and sleep from the river?—The distance within which I attend them would be within at any rate two miles of the river; they are scattered about.

15,502. (*Chairman.*) Do they live as far as two miles back inland from the river?—Some of them will live nearly over by Victoria Park, but the majority of them live within about half a mile of the river.

15,503. (*Mr. Michael.*) Are you also in general practice in the district attending persons living close to the river?—I am.

15,504. Are you able to say whether zymotic diseases prevail more largely close to the river than at a distance from it?—The people are very healthy about Poplar.

The witness withdrew.

Dr. Walter Dickson called in; examined by Mr. Michael.

15,505. You are a doctor of medicine of the Royal Navy, and have been for the last 21 years Medical Inspector of Her Majesty's Customs?—I have.

15,506. I believe among the duties appertaining to your office is that of supervising the health of the subaltern custom-house officers of the Port of London?—It is.

15,507. They consist of about 1,000 persons?—Yes, they have averaged about that number.

*Dr. W. Dickson.*

15,508. How long are those officers occupied in the day?—The time varies; those who are employed on day duty are at work from 8 to 12 hours, but many have night duty as well, and Sunday duty. For example, ships arriving off Gravesend are boarded by

*Dr. W. Dickson.*

13 June 1883.

officers at Gravesend, who board the ship and remain on board for the protection of the revenue until all the cargo is discharged, and those men spend all their time, day and night, on board the ships, except for a day or two occasionally, when they go to their homes at Gravesend.

15,509. Do you think that the night duty may be said to be entirely upon the river?—Yes; and those men on night duty would number about 500 men out of the whole number.

15,510. Are all those men employed upon the river, either day or night?—No, not altogether at the same time.

15,511. What proportion of them would be?—If you include the wharves and the docks, I should say three-fourths of the whole number of customs officers are employed on or upon the margin of the river.

15,512. (*Chairman.*) What did you say was the average number employed upon the river all the year through, taking day and night?—I should say not less than 500, or certainly not less than 400, actually on the river at one time.

15,513. (*Mr. Michael.*) Have you a section of your men who live almost constantly upon the river called the watermen?—Yes, they are very much upon the river; they are employed in what is called "rummaging." When a vessel comes in from abroad, they go and search her, down the holds and underneath the boilers, in quest of tobacco, which is usually the object of their search; and they are exposed to great changes of temperature; and, moreover, the commercial pressure is such, owing to the anxiety to get the cargoes discharged as quickly as possible, that they are employed at all hours for the purpose of rummaging.

15,514. All those men have very laborious duties to perform, and are much exposed to the weather?—Yes, they are.

15,515. A considerable number of them are constantly on the river itself, day and night?—Yes, they are.

15,516. Are you able to say what the health of the men is?—Considering the nature of their duties, I look upon it as remarkably good; the per-centage of the sick is about 3½ to 4 per cent. I have gone into the statistics very minutely for about 21 years, and that is the proportion; it is very rare that more than 3 or 4 per cent. are disabled from their duty, either by disease or accident.

15,517. (*Chairman.*) But we have nothing to do with accident here, so you must eliminate those?—You might say 3½ per cent. then as the average number of the sick.

15,518. (*Mr. Michael.*) Can you say whether zymotic diseases prevail amongst them?—They are exceedingly rare; they are almost unknown.

15,519. I see you have had only two fatal cases of cholera recorded within the last 26 years?—Yes.

15,520. And they were sporadic?—Yes, I believe so. One case occurred in 1861, at the time of the great fire at London Bridge, when the man was exposed to great fatigue, and he took the cholera, and died; but, I believe, there was no cholera in or near England at that time. The next case was in the year 1866, when cholera was epidemic in London, and when, although we had no cholera in the Customs force, we had a great deal of choleraic diarrhœa; but the case of the man who died was a case evidently self-induced. He was in perfect health, and, like many people, wishing to be better, took a couple of Cockle's pills, which brought on profuse purging, which became cholera, and he died of the consecutive fever in a few days.

15,521. Do a large number of your men live at Gravesend?—About 250.

15,522. Are you able to tell the Commission what is the health of the men?—It is very good, even better than the health of the men in London.

15,523. I think you have weekly returns, have you not, of the health of all your men forwarded to you?—Yes, I have.

15,524. You, in fact, have the general superintendence of the sanitary condition of the whole of your men?—Yes.

15,525. Would you give your opinion to the Commission as to the general state of health with respect to zymotic diseases of all the men under your charge, or whom you take cognizance of?—It is very good; singularly good.

15,526. Have you been able to trace, in any single instance, any case of zymotic disease originating or caused by the condition of the river?—No case.

15,527. Could such cases occur amongst your men without its being brought under your cognizance?—It would be impossible; they cannot be withdrawn from duty without my knowing it; they have every encouragement to apply; they suffer no stoppage of their pay for six months; they are treated most liberally; so that no case of illness could occur without my knowing it.

15,528. (*Chairman.*) Are the men attended free of charge by yourself?—Yes, and they are also supplied with medicine.

15,529. (*Mr. Michael.*) I think Dr. McWilliam was your predecessor?—Yes, he was.

15,530. He speaks of the very bad condition of the river antecedent to the opening of the sewage outfalls?—He does.

15,531. Are you yourself much upon the river?—Not at present. I was some years ago. I made use of boats to cross to Bermondsey and Rotherhithe, but it has become so very dangerous to go across in boats, on account of the steamers, that I have abandoned it, and go round by London Bridge or by the East London Railway.

15,532. (*Chairman.*) Where do you live?—I used to reside on Tower Hill; now I live in the suburbs: but my office is upon the Custom House Quay where I am occupied usually four or five hours a day.

15,533. (*Chairman.*) Have you any considerable number of your men residing at the Custom House; or can you name any particular point upon the river where a number of the men of the Customs are concentrated?—No, they are widely scattered in the suburbs.

15,534. Gravesend is the only point upon the river where the men that are employed in that department are concentrated?—Yes, it is.

15,535. (*Mr. Michael.*) Have you ever had it brought to your notice, as medical superintendent, that disease has resulted from the condition of the river?—No, I have never known any case of that kind either in my own experience or in the experience of others.

15,536. (*Dr. Stevenson.*) In the years 1858 and 1859 that you have spoken of, do you know whether disease was prevalent upon the river?—I do not know the circumstances except from Dr. McWilliam's reports. He says that diarrhœa was not more prevalent then than in any other year; but an extract from his report is to be read, I believe, before the Commission.

15,537. (*Chairman.*) Have you observed the condition of the river water from time to time during your term of office?—Do you mean with regard to offensive smells?

15,537a. Yes?—Occasionally I have perceived such smells, but very rarely.

15,538. One would expect that you had from your official position noticed the state of the water?—Yes: occasionally, when the tide is low, as there is a mud bank in front of Custom House Quay, there has been in hot weather a little smell; occasionally in other parts of the river I have observed an unpleasant smell in hot weather, when the mud has been stirred up by the steamers, but not lately.

15,539. Comparing the last 10 years of your period of office with the first 10 years, what would you say was the relative condition of the river during those two periods?—I should say it is much improved.

15,540. That is to say, as to smell?—Yes, as to smell.

15,541. And as to appearance?—Yes.

15,542. (*Dr. Stevenson.*) What part of the river do you include in your remarks?—I seldom go further down than the East India Docks.

15,543. (*Chairman.*) I gather that you have no intimate acquaintance with the part of the river at the two outfalls?—I have never been there; our officers board the ships at Gravesend, and my duties do not call me farther.

15,544. Then, when you go to Gravesend, do you go by water?—No, I generally go by train.

15,545. But you would be familiar with complaints if there were any?—I certainly should have heard complaints made if there had been any to make. I have asked the officers sometimes, and they tell me there is no great nuisance of that kind experienced on board the ships.

*Dr. W. Dickson.*

13 June 1883.

Cross-examined by Mr. Lumley Smith.

15,546. Are the Custom House officers examined medically before they are taken into the service; are they certified to be strong healthy men?—Yes, they are.

15,547. When did you start your term of office?—In 1862.

15,548. My learned friend, Mr. Michael, asked you about the report of Dr. McWilliam; would you kindly refer me to it?

(*The same was handed to the learned Counsel.*)

15,549. Does this refer to the part below the outfalls?—No, to the whole river. I find that such smells as we now suffer from at the Custom House are due to the Billingsgate Market.

15,550. I find in this report, "It was at this time that the river," that is, in June 1859, "that the river "and the docks began to smell most offensively, and "serious apprehensions for the public health were "entertained. Some of the men complained of "nausea, and occasionally of headache,—symptoms "which they ascribed to the foul state of the river; "but although there were a few cases of diarrhœa of "sufficient severity to cause temporary absence from "duty, that disorder certainly was less rife than "during the previous year, when the odour from "the river was also noisome in smell, but by no "means to the same extent as during the hot months "of the past year." "Notwithstanding the dock "and river effluvia evolved by the action of high "temperature, the waterside department also continued "healthy, and to a degree almost unprecedented in "the service, 35 officers only in 529 strength having "been placed on the sick list during the quarter." That is the extract you are speaking of, is it not?—Yes; there may be others even stronger.

15,551. Then I find "Third quarter, the health "standard of both departments was high during this "quarter, and that of the general population was also "above the average, although diarrhœa prevailed to a "considerable extent in some of the districts of "London. The temperature of the air in July was "below, in August slightly above, and in September "as much as four degrees above the average. The "rainfall was below the average. The foul state of "the river still continued to excite some apprehension "of danger to the public health; but in the water-"guard and waterside departments, as I shall hereafter "endeavour to show, there was less of bowel affections "than there had been at the corresponding period of "any year since the cholera epidemic years. There "was no case of death in either department during "the quarter." He seems to have thought that the bad state of the river might be bad for the health?—But it turned out not to be so as far as regards bowel complaints.

15,552-3. Have you any reports that you have made since you have been there?—Yes, I have reports very nearly of the same character, going minutely into the effect of seasons, &c. upon the health of the men; the cold winter is our most injurious factor of disease.

(*Chairman.*) Have those any material bearing upon our inquiry. They seem to show that injury to health was apprehended.

(*Mr. Michael.*) And did not take place.

*Mr. Beaumont Morice* stated that he had no questions to ask the witness in cross-examination.

The witness withdrew.

Mr. William Joseph Dibdin called in; examined by Mr. Michael.

15,554. I believe you are a Fellow of the Institute of Chemistry and a Fellow of the Chemical Society?—I am.

15,555. Were you assistant to the late Mr. Keates, the Consulting Chemist to the Metropolitan Board of Works?—I was.

15,556. For how long were you his assistant?—For about five years.

15,557. And since his death, I believe you have been Chemical Assistant to the Metropolitan Board of Works?—I have.

15,558. I believe that you have personally made all the analyses in a book which I am about to put in?—I have.

15,559. And you have also made a considerable number of analyses in a book to be put in subsequently by Dr. Dupré?—That is so.

15,560. You have made, have you not, a series of investigations as to the condition of the river?—Yes.

15,561. And especially with respect to the effect produced upon the river water by the sewage which is introduced into it?—From the Metropolitan Board's outfalls, yes.

15,562. In 1878 there were two series of investigations carried out under the direction of Mr. Keates, and a great many analyses were made by you for him?—Yes, those are the analyses made in reply to the report by Captain Calver.

15,563. Then in 1880 did you make another series of analyses?—In 1878, beginning in January, February, and March, the first series was made, and then later on, in October and November, a second investigation was made in consequence of the accident to the "Princess Alice," and in 1880 the investigations were renewed.

*Mr. W. J. Dibdin.*

15,564. What was the main object you had in view in making those analyses?—To ascertain the character of the river water, as to whether it was impregnated with sewage to such an extent as to be injurious to the health of those travelling upon the river or living in the neighbourhood.

15,565. What process have you mainly adopted?—The process which has been particularly adopted in the analyses I have carried out to ascertain the quantity of sewage is that which is known as Wanklyn's ammonia process, that is a process which gives an index to the amount of nitrogenous organic matter present in the water.

15,566. I believe this is a delicate and trustworthy mode of ascertaining the amount of impurity present in the water?—Decidedly.

15,567. (*Chairman.*) Is it the best you know?—It is.

15,568. And is it so recognised?—It is; it is the one recognised and adopted by Professor Way in the analyses he has put in, and in the experiments he has described, and it is one which I am satisfied is a reliable process. It is not one which gives the absolute amount of organic matter, but it gives the relative amount.

15,569. (*Mr. Michael.*) Having adopted it for

*Mr. W. J. Dibdin.*

13 June 1883.

your purposes, are you able to bring before the Commission the comparative purity of those waters which you have examined, and which are set forth in your table?—I am.

15,570. To commence with, you took the sewage itself, did you not, as delivered both at the northern and at the southern outfalls?—Yes. A series of samples was collected from the sewers as the sewage was running into the reservoirs, so that we might have the sewage pure and simple, and independent of the river water; because when it gets into the reservoir a sort of settling down takes place, whereas we wanted to get a fair average of the actual sewage.

15,571. (*Chairman.*) You are speaking of the sewers at the outfalls, are you not?—Yes, at the outfalls.

15,572. (*Mr. Michael.*) Did you determine from the sewage itself as it entered the reservoir, taking that as a fair test, what quantity of organic ammonia was to be found in the sewage?—I have here a series of analyses which has been made of the sewages. I am sorry to say the copy has not come from the press, I have only a proof at present. I was in hopes that the tables would have been ready for my evidence this afternoon, and I may say we expect them immediately, and as soon as they arrive we will put them in.

15,573. What is the quantity of ammonia per gallon in the London sewage? — Of albuminoid ammonia the average quantity in the series of samples I have examined is equal to ·366 of a grain per gallon.

15,574. That is rather more than one third of a grain per gallon, is it not?—Yes; there are some samples which contain a considerably higher quantity and others a less quantity.

15,575. How many analyses have you made in order to arrive at your average of ·366 of a grain of albuminoid ammonia in a gallon of sewage?—One hundred and eighty-one samples, which were collected at intervals of four hours from each outfall.

15,576. (*Chairman.*) Were the samples taken at regular intervals of four hours over the whole 24?—Over the whole 24.

15,577. (*Mr. Lumley Smith.*) Are the north and south samples mixed?—No, they are separate.

15,578. (*Mr. Michael.*) The details of those analyses you will put in to the Commission as soon as they arrive?—I will. (*See Appendices* BX *and* BY).

15,579. In order to find the quantity of albuminoid ammonia in water to compare with sewage, what kind of water did you take to furnish you with the means of comparison?—The ordinary Thames filtered water as supplied by the London water companies; and upon that I found from a number of analyses that the albuminoid ammonia which is in the sewage is ·366, whereas in the filtered water it is ·005 or $\frac{5}{1000}$ths of a grain per gallon.

15,580. You adopted the same method of analysis in the two cases?—Yes; exactly the same conditions were adhered to in the analysis of each, so that the results in either case might be strictly comparative.

15,581. Having ascertained those two points of comparison, what did you do subsequently?—We examined a number of samples from the river. Samples from the river have been examined at different periods down to the present time. This particular series of sewages I am mentioning were carried out through the months of March, April, and May of the present year.

15,582. (*Dr. Stevenson.*) The samples were not taken at four hour intervals consecutively, were they?—The sewages were taken consecutively in the month of March, on the 23rd, 24th, and 25th; they were taken through the months of March, April, and a portion of May, so that not a single day was missed during the period of collection, with the exception of one or two Sundays, at the northern outfall.

15,583. (*Mr. Michael.*) Otherwise, it was a consecutive series of four hours samples?—Yes.

15,584. (*Dr. Stevenson.*) What were the hours at which they were taken?—They commenced taking them at the Southern outfall at 6 and 10 a.m., and 2 p.m., 6 p.m., and so on every four hours. I then gave instructions that those hours should be varied, and they commenced taking them at hours varied so as to follow the tides; as the tides varied so they varied; so that we have the times at which the samples were taken in the day, varied at intervals about 40 minutes later each day.

15,585. (*Mr. Michael.*) Was that with the object, if there is any variation in the quality of the sewage from time to time, that you should exhaust the whole of the possibilities so as to get an absolute average of the quantity of putrescible matter in the sewage itself?—That is so; every care was taken that the results of those analyses should give a fair indication of the character of ordinary London sewage.

15,586. Do you think you have really got now an absolute standard to go upon of the quantity of putrescible matter in the London sewage as discharged at the two outfalls?—I believe so.

15,587. Having got those two sets, how did you proceed in order to determine the effect upon the river water of the projection of the sewage into it at the outfalls?—Samples have been examined at different times of the sewage as it was discharging into the river water, and samples of the water have been collected outside, that is to say, upon the river side, of the line of junction of the sewage and river water.

(*Chairman.*) Those of the Commission who went down saw very clearly the line of demarcation between the sewage and the river water.

(*Witness.*) I shall be able to show you very clearly the difference.

15,588. (*Mr. Michael.*) You say that there is a clear line of demarcation to be observed in the river where the sewage is for the first time allowed to get into the river itself—you can see where the sewage is, and you can see on both sides where practically the sewage is not?—That is so.

15,589. And in order to make it perfectly clear to the Commission, you have taken samples, have you not, first in the line of the sewage itself, and secondly on both sides of it?—Yes, that is so.

15,590. Will you explain in your own way what the steps were that you have taken, and how many analyses, and so on, in order to arrive at a determination of what quantity of putrescible matter was to be found in the sewage in the river at various points and at various states of the tide? — Perhaps the Commission will kindly turn to Diagram No. 1, at the end of the series of tables, which shows the "quantity of albuminoid ammonia yielded by samples "collected on shore side and mid-stream side of line "of junction of sewage and river water at the "northern outfall, while sewage was discharging" on October 15th, 1878, which is represented by the blue line, and August 11th, 1880, which is represented by the red line. The actual figures of the analyses are given on page 11, Nos. 203 to 206.

15,591. Is this diagram drawn to scale?—Yes, the scale is given at the side; 1 inch in height represents one-tenth of a grain per gallon. The amount of albuminoid ammonia on the shore side of the line of junction in the sample collected on October 15th, 1878, is shown to be ·254, while in the mid-stream side, the short blue line, it is ·067. On August 11th, 1880, a sample collected on the shore side of the line of junction of sewage and river water was ·207 and upon the mid-stream side it was ·027. The sample collected on August 11th, 1880, was collected from a boat which was placed at right angles to the stream; the sample of the sewage being taken at one end of the boat, and the sample of the river water being taken at the other end of the boat,—so that the samples were taken very close together.

15,592. (*Professor Williamson.*) Was the boat drifting with the current? — It might have been drifting with the current.

15,593. (*Mr. Lumley Smith.*) The two samples, you say, were taken, one at each end of the boat?—

One sample was taken at each end of the boat, the first sample being in the sewage, the second being in the river water.

15,594. (*Mr. Michael.*) The line of demarcation enabling you to make a distinction between them?—Yes, that being about midships.

15,595. (*Chairman.*) Is there any reason why these two particular dates were selected?—They happen to be samples taken at different times; they were taken with the view of showing this fact that the line of demarcation is very sharp indeed.

15,596. But my question has reference to those particular dates?—No, I think there was no special reason for the selection.

15,597. (*Prof. Williamson.*) The line of demarcation is very sharp near the outfall, I presume not anywhere else?—Yes, those are taken at 200 feet and 600 feet from the northern outfall, and on one occasion on the north side they were taken when there had been an overflow of an hour, and a second sample was taken at nearly the same position as the last, but 12 feet from and on the mid-stream side of the line of direction of sewage and river water, so that those two samples which were both taken upon the 11th August, 1880, were only 24 feet apart.

15,598. (*Mr. Michael.*) The sample taken upon October 15th, 1878, was taken in consequence of the "Princess Alice" disaster, was it not?—Yes.

15,599. That was about six weeks after the accident, I think; the accident was upon the 3rd September?—Yes, it was. Complaints were made at the time of the state of the river, as the Commission are well aware, and the Board ordered the analysis to be made.

15,600. Now, having explained diagram No. 1, will you come to No. 2, and tell the Commission what that is intended to represent?—No. 2 shows diagramatically the analyses which are given in table No. 5 upon the same page, No. 207 to 225. The Commission will see that there are four series of samples collected in the line of sewage flowing from the northern outfall.

15,601. What is the object of the diagram?—The object of the diagram is to show the decrease in the quantity of albuminoid ammonia yielded by samples collected in the line of sewage flow from the northern outfall on October 15th, 1878, as represented by the red line; on March 13th, 1882, as represented by the red dotted line; on August 11th, 1882, at the surface, as represented by the blue line, and upon the same date at three feet above the bed of the river, as represented by the blue dotted line. On October 15th, 1878, it will be seen that the quantity of albuminoid ammonia yielded by a sample collected off the outfall in the sewage showed albuminoid ammonia equal to ·254. A sample taken at Barking Creek yielded ·186. But it will be seen that following the red line of October 15th, 1878, it decreases at False Point.

15,602. (*Chairman.*) This is the first time we have heard of False Point, will you tell us where it is?—It is below the Barking Guano Works.

15,603. (*Mr. Michael.*) Will you tell the Commission, if you please, what time elapsed between your taking those various samples?—The first sample opposite the northern outfall was taken at 3.50 p.m., the second sample in the course of the sewage at Barking Creek was taken at 4.5 p.m. Then the collector went further down, collecting samples off False Point, and then between the two powder magazines, and again off Crossness Point, by which time, when he arrived at Crossness Point, it was 5 p.m., so that the sample off False Point and the one between the two powder magazines must have been taken at some period of time between 4.5 and 5 o'clock, the boat rowing from point to point, the interval of 55 minutes being occupied in taking samples and moving from place to place.

15,604. May I take it generally as the result of your observations that you have found any considerable difference between the condition of the water at the surface and some distance below?—No, there is practically no difference between the water at the surface and the water just above the bed of the river. You will find that the diffusion of the sewage and river water is complete, there is very little difference between the samples. But dealing with the sewage from the outfalls, following it down the river, the mixture of the sewage with the river water is very complete indeed.

15,605. (*Mr. Lumley Smith.*) Is it the same all the way down, do I understand, from the surface to the bottom?—If you look at diagram No. 2, the blue dotted line shows the amount of albuminoid ammonia yielded by samples collected on August 11th, 1882, at the surface and three feet from the bottom.

15,606. (*Chairman.*) But supposing the water were 40 feet deep there, what would it be at 30 feet from the surface. I understood you just now to say that the composition was very nearly uniform from the surface to the bottom?—Yes.

15,607. That is your general conclusion derived from a number of observations?—Yes.

15,608. (*Mr. Michael.*) How do you find it with respect to the suspended matter, is there any difference?—With respect to the suspended matter, there is no doubt that some of the heavy particles of the suspended matter, the sand, and so on, would have a tendency to settle to the bottom of the river, but the suspended matter in the sewage is very much lighter, about half the gravity of the river suspended matter.

15,609. Then that uniformity you referred to just now refers to the solubility of the albuminoid ammonia?—Yes. I should have mentioned that in all the samples given here the suspended matter has been allowed to settle in the bottle in which the sample was taken, and the clear water taken for the purpose of examination, the suspended matter having in many cases been examined separately.

15,610. (*Prof. Williamson.*) Is there a uniformity with regard to the chlorine corresponding to that which you have mentioned in regard to the albuminoid ammonia?—In Table No. 5, samples 207 to 211, on October 15th, 1878 (which are a series from the Northern Outfall to Crossness Point), show that there is a gradual increase in chlorine from the outfall down the river, because, when the sewage meets with the river water, the quantity of chlorine is less: the more sewage, the less chlorine.

15,611. But at different depths of water you said the proportion of albuminoid ammonia was the same. Now at different depths is the quantity of chlorine the same?—Not precisely, but there is a very close accordance. In the sample at the surface on August 11th, 1882 (*referring to No.* 218), immediately off the outfall the chlorine was only 40 grains, but three feet above the bed of the river the chlorine was 138 grains, that is immediately off the outfall, when the sewage was discharging into a considerable depth of water. But if we follow it down to Lawes' Chemical Works, which are just the other side of Barking Creek, we find that at the surface the chlorine was 361, while three feet above the bed of the river it was 394, showing an excess of 33 grains. Then further down, 200 yards above the Land Powder Magazine, upon the surface the chlorine was 392, and three feet above the bed of the river it was 398, showing that the mixture was still more complete. Whereas, if we go to Crossness Point on the same day, we find a slightly greater difference, the excess of chlorine being still in the bottom of the river: a fact which is always found in examining river water, that the chlorine is always in excess at the bottom, independently of sewage.

15,612. It would seem strange if in any water the albuminoid ammonia were to be perfectly constant at the different depths, and the chlorine to be different; one would think they must go together. If there is a complete mixture, the albuminoid ammonia will be uniform; if there is not a complete mixture, they will be different?—There is not a complete admixture at the outfall, but as you get a few hundred yards down, the quantity of chlorine in the surface and bottom samples is tolerably constant.

*Mr. W. J. Dibdin.*

13 June 1883.

15,613. It was an appreciable difference at Lawes' Works?—At Lawes' Works it was 391 and 394.

15,614. (*Chairman.*) When were the samples taken?—These samples were taken on the ebb.

15,615. (*Prof. Williamson.*) May I ask this question in order to save unnecessary trouble to yourself and to the Commission. What bearing do you conceive that there is between the proportion of albuminoid ammonia in the water and the proportion of sewage, because you know perfectly well that albuminoid ammonia ceases to be albuminoid ammonia in proportion as the material gets decomposed: the nitrogen is there, but no longer combines in that way; so that, if you got a cubic foot of sewage, that cubic foot does not after a while contain as much albuminoid ammonia as it did at first, so that the albuminoid ammonia is not a fixed and permanent mark of sewage. Therefore what interpretation do you put upon these facts regarding the amount of albuminoid ammonia in the river at different places, have they a direct bearing upon the quantity of sewage in it?—Undoubtedly; I think the analysis will show that if we take sewage we get a very considerable quantity of organic ammonia, if we take sewage *plus* river water, we get a very considerable decrease in the albuminoid ammonia in accordance with the degree of dilution; so we may take the quantity of albuminoid ammonia as an index of the quantity of sewage-matter present.

15,616. You mean the quantity of organic matter which is in the sewage?—Precisely.

15,617. If you use the term "sewage" as meaning the quantity that was in it when it flowed out, that is one thing; but if you use it as indicating the amount of organic matter that was in it, that is another thing. The sewage constituents are measured by the albuminoid ammonia, but when they are decomposed the albuminoid ammonia is no longer there as albuminoid ammonia?—No, that is so.

15,618. But the engineers have been speaking of the decomposed liquid as if it were still sewage?—I am speaking of the sewage when it is in such a condition that it yields a certain amount of albuminoid ammonia to analysis. When the character of the sewage is so altered that it no longer yields that quantity of albuminoid ammonia, I speak of it as water.

15,619. When it is liable to be noxious or unpleasant, do you consider the albuminoid ammonia is the measure of it; that it is noxious by reason of the albuminoid ammonia, or when it is decomposed?—The general bearing of these facts is that the albuminoid ammonia is now taken as an index of the amount of putrescible nitrogenous organic matter, and I am speaking of the sewage in regard to the amount of putrescible nitrogenous organic matter.

15,620. When it has putrified then it is noxious?—When it is in a putrid condition I take it we shall still get a certain quantity of albuminoid ammonia.

15,621. As far as it is not decomposed, the ammonia is albuminoid; when it is decomposed it is no longer albuminoid?—When the decomposition is complete we shall no doubt lose the albuminoid character of it.

15,622. (*Mr. Michael.*) Will you explain, in order that the Commission may understand it, the object of your tables. You have taken first, have you not, the quantity of putrescible matter which is found in the sewage; you have taken some pure standard; you have taken, I believe, the water into which the sewage has been poured in order to have some test at first of the quantity of sewage which exists in the water at the moment of leaving the outfall; am I right to that extent?—That is so.

15,623. Then immediately afterwards do you say that any changes do or do not take place in the condition of the sewage as it is poured into the water?—Undoubtedly they do.

15,624. Changes take place, destroying the condition in which it is poured into the water?—Undoubtedly.

15,625. Are you endeavouring by your tables and diagrams to trace these changes, and to show what the condition of the water is quâ the sewage that has been first poured into it?—Yes.

15,626. Is that the object you have in view, whether rightly or wrongly, in putting forward these tables?—Yes.

15,627. (*Professor Williamson.*) But to trace the changes, I consider one would require to know two things. In the first place, the actual number of cubic feet of sewage in particular places mixed with the unit quantity of water, and at the same time the proportion of albuminoid ammonia in each cubic foot of sewage. You would require to have an independent record of the amount of sewage which flows out of the outfalls, and to see whether the albuminoid ammonia remains in the same proportion to that, or whether it varies?—All my results are stated in grains per gallon, so that the quantity of albuminoid ammonia I have found is that which would be yielded by a gallon of water or sewage, or a mixture of water and sewage.

15,628. (*Mr. Michael.*) Have you taken three analyses, first in mid-stream, which may be said to be nearly all sewage, then the sewage on both sides of the stream where the sewage has commenced to mix with the water, and then have you traced subsequently the alterations from the changes which the sewage undergoes?—Yes.

15,629. You regard, as I understand, the quantity of albuminoid ammonia in the matter as a distinct and correct measure of the putrescible matter which is in the sewage?—Yes, of the nitrogenous putrescible matter.

15,630. Another as that falls away, this becomes less and less putrid, not only less putrescible, but less and less putrid?—The quantity of putrescible matter is less, the actual quantity present is less.

15,631. May it not be capable of becoming more and more putrid, although the quantity may be less?—By putrefaction and oxidation there is no doubt it does undergo a very rapid alteration indeed. The object of the analyses and tables is to show that change, that is, the change in the quantity of putrescible nitrogeneous organic matter which is present in a given quantity of that water.

(*Mr. Lumley Smith.*) And not of the non-putrescible?

15,632. (*Mr. Michael.*) That is due to two causes; the first, a very important one, is dilution, being mixed with a very large quantity of water?—Yes.

15,633. And secondly changes occurring of a chemical and physical character, owing to some substances with which it comes in contact in the water itself?—That is so.

15,634. The sum of those two differences you are now giving; the amount attributable to each of those you have not come to?—I have not given that, except that in the sewage there is a certain amount of nitrogenous organic matter which is indicated by the amount of albuminoid ammonia yielded to analysis. In the water there is a less amount, and we find there is a certain quantity in ordinary London drinking water.

15,635. (*Chairman.*) I should like to be clear about it. It is clear that the proportion of putrescible matter is becoming less and less very rapidly. Now there may be a less quantity of putrescible matter, but has it arrived at what I may call its maximum putridity, has it become as putrid as it will ultimately become?—That I think it is impossible to say.

15,636. (*Dr. Stevenson.*) You deal with what is undergoing putrefaction and also with what is capable of becoming putrid?—Yes, the total quantity; it may not at the time be in an offensive condition, but it would become so afterwards.

15,637. (*Chairman.*) You say these samples are collected in the line of sewage flow from the northern outfall?—Yes.

15,638. What we saw when the Commission were down there was that the line of demarcation between the sewage water and the river water was very clear to somewhere about False Point; but below that point, looking to the particular configuration of the river the,

sewage would be distributed over the whole river width?—It is so.

15,639. Then, in fact, that marked sewage flow would apply to False Point and not beyond?—Upon certain occasions you can see it further down.

15,640. (*Mr. Michael.*) Would you point out to the Chairman where you followed it, it is a regularly diminishing shade of difference?—If you turn to No. 210 in mid-channel between the two powder magazines, which is a short distance below False Point, the albuminoid ammonia is reduced to ·061, it is first seen to be ·254, then ·186, then ·063, then ·061, and ·025 off Crossness Point. At No. 209 a note was made by the collector that off False Point the sewage was traced thus far, but that "in mid-channel between two powder magazines no trace of sewage could be seen," and again, "Off Crossness Point no trace of sewage observable."

15,641. (*Chairman.*) Then below False Point the sewage, whatever the quantity of it may be, is pretty fairly distributed over the whole of the river?—That is so.

15,642. (*Mr. Michael.*) Would you begin with diagram No. 3, showing the amount of albuminoid ammonia from the southern outfall?—"Showing the "decrease in the quantity of albuminoid ammonia "yielded by samples collected in the line of sewage "flow from the southern outfall on March the 15th, "1882."

Examination continued by Mr. Bidder.

15,643. In the diagram No. 3 upon the southern outfall there is a very remarkable thing, is there not?—The table of analyses of the proportion of albuminoid ammonia on page 12 shows that the quantity of albuminoid ammonia yielded per gallon by a sample collected immediately at the outfall was ·336, decreasing to ·066 above Crossfield's manure works. I should mention that those are taken from the southern outfall to Jenningtree point. Above Crossfield's manure works, as I say, it is ·066, the sample being taken a short time after 9.30, the exact time not being given; it took from 9.30 to 11 o'clock to take the samples from the outfall to Jenningtree Point. The albuminoid ammonia off the powder magazine further decreased to ·036, off the manure factory it was about ·038, at near Jenningtree Point ·033, and off Jenningtree Point ·028. The diagram shows all that very clearly; the diagram is drawn to scale, so that the relative distances can be seen at once.

15,644. Then I believe you wish to take diagram No. 5 next, will you just explain in your own way what is the particular object of this diagram. I see it shows that during the whole of that period the maximum of albuminoid ammonia was ·042?—The analyses of those samples is given in Table No. 2, page 3.

15,645. (*Dr. Stevenson.*) I see the vertical lines are ten times the value that they were in the other tables?—Yes; because in this case I am dealing with river waters, and it would have been impossible to have got it upon the paper upon the same scale as in the other diagram. The analyses are on page 3, they are a series of samples of river water collected off Woolwich arsenal in mid-stream, at high water and one hour after high water, from August 12th, 1880 to October the 18th, 1880.

15,646. (*Mr. Bidder.*) In the first place, the maximum upon any occasion is ·042?—The maximum is ·042 on October the 12th.

15,647. Usually the general run of that diagram shows that the albuminoid ammonia was very much below that?—Taking the average of the whole, it is ·028. The minimum of albuminoid ammonia in those samples was on August 12th and September 23rd, when it was only ·021.

15,648. There is a very remarkable thing about that diagram, you have also plotted upon that diagram in dotted lines the amount of chlorine?—Yes, I have plotted out upon that diagram the amount of chlorine.

15,649. Which of course gives a rough idea of the proportion of sea and fresh water?—That is so.

15,650. All the samples were taken at corresponding periods of the tide, were they not?—The high water sample being taken at the top of high water, and the other about one hour after high water.

15,651. It is a curious thing to notice upon that diagram that the occasion when the pollution was at its maximum as indicated by the albuminoid ammonia, viz., the 12th October, was the occasion when the chlorine was at its minimum, showing that it was the occasion when floods had reduced the proportion of the sea water to an abnormal extent?—Yes.

15,652. When the proportion of water from above was greater than the sea water?—Yes, that is so.

15,653. On the 9th of October 1880 the chlorine drops in a very remarkable manner, whilst at the same time the albuminoid ammonia jumps up upon the diagram?—Yes, that is so.

15,654. (*Dr. Stevenson.*) May I ask how you explain that?—I can only explain it by presuming that the character of the water that comes down the river was as impure as that which is in the neighbourhood of Woolwich at any time, or more impure; because it is a notable fact, if you look at this diagram, that, the higher the quantity of sea water which must come up from below the outfalls and with the sewage in it from the outfalls, the less the pollution as indicated by the albuminoid ammonia.

15,655. (*Mr. Bidder.*) The dotted line here represents the chlorine or sea water, and the sea water only comes to Woolwich after passing the outfalls?——Yes.

15,656. Therefore the dotted line here represents the water at Woolwich which has come past the outfalls?—Yes.

15,657. (*Chairman.*) I take it that the analyses for chlorine and albuminoid ammonia are taken from the same sample?—They were, that is most important.

15,658. (*Mr. Bidder.*) Consequently, when the dotted line rises, the proportion of water from below Woolwich to the water coming down from above is greater. When the dotted line falls the proportion of land water is greater?—That is so.

15,659. Indicating floods, I suppose, in the upper river?—Yes.

15,660. So that we see that the general rule upon the face of this diagram is that when the proportion of water which is coming past the outfalls to Woolwich is less the pollution is less, but that when the proportion of water from above Woolwich is greater the pollution is greater?— Yes, that series of gaugings shows that most distinctly.

15,661. Indicating that the main causes of pollution at Woolwich are rather to be sought above Woolwich than below?—They certainly do not come from the neighbourhood of the outfalls.

15,662. I see you have indicated another thing. You have indicated when the spring tides occurred, and, as one would expect, we see that with the spring tide there comes an accession of chlorine?—Yes, and a lower proportion of organic pollution.

15,663. (*Mr. Lumley Smith.*) Have you corresponding observations upon the same day at low water?—No; the difference between those samples is not very great, taking the general result. The lines in blue, which represent high water, and the red lines one hour after high water, cross one another, but out of the 20 days upon which the samples were collected the high water was the best upon 13 days.

15,664. (*Mr. Bidder.*) Do you point out that, comparing the blue line, which is the sample at high water, with the red line, which is the sample an hour afterwards, and which is water coming from higher up the river, in 13 days out of 20 the blue line is the

*Mr. W. J. Dibdin.*

13 June 1883.

better of the two?—The blue line is the better of the two.

15,665. The red line is more frequently above the blue line, showing that the water which came from higher up the river was more polluted than that which came from lower down?—Yes, that is so.

15,666. Diagram No. 6, I think, is the next?—Yes.

15,667. That represents samples taken the next year?—Yes, they were taken from 15th August to 5th December 1881.

15,668. Those were taken an hour before high water, were they not, off Woolwich Arsenal?—Yes, and the analyses are given on Table 3, Nos. 95 to 102.

15,669. Here your two colours represent something different from what they have done in the previous diagrams?—Yes.

15,670. All the samples are taken an hour before high water, but your red line represents the mid-stream sample, and your blue line the one near the shore?—Yes, over low-water mark, taken one hour before high water, one sample in mid-stream, and one sample over low-water mark.

15,671. (*Chairman.*) You mean vertically over low-water mark?—Yes.

15,672. (*Mr. Bidder.*) The red is rather the better of the two as a rule?—The general result of the analyses shows a slightly higher degree of organic pollution, but very little; the curve represents the relative quantity of the organic ammonia. The mid-stream samples will be seen to contain less impurity than those collected off the shore. The red line runs generally underneath the blue line; there are variations, the lines crossing one another now and then, but, on the whole, there is a less pollution in the mid-stream samples, and this is one hour before high water, when the water was running up the river from the outfalls.

15,673. How does the question of the contrary action of the ammonia, as compared with the chlorine, show upon that diagram. It seems to indicate, though not so strongly, the same thing?—Though not so strongly, yet decidedly the same tendency is shown there that, the lower the chlorine, the higher the pollution.

15,674. You have some samples in October 1880 and in November and December 1881. Do they relate to any diagram? There are some prominent instances, I think, which bring out very clearly what you have already indicated, that the water at Woolwich is largely affected by some source of contamination higher up the river?—The analyses seem to show that. I do not pretend to explain it, but certainly that is the conclusion one is obliged to draw from a consideration of the analyses. The average quantity of albuminoid ammonia in the Woolwich samples during 1881 varies a little from those examined in 1878, and later in 1882. The variation is very slight, but such as it is, is in favour of the present period. In 1878 the mean quantity of albuminoid ammonia from samples collected off Woolwich was ·0317, in 1880 it was ·0286. At Woolwich, in 1878, you will find on page 1 of the Tables and on page 4, Woolwich, 1880, it is ·0286, showing rather a decrease. In 1881, if we take the samples from the same spot at Woolwich Arsenal, it is ·0373, which is rather a higher degree of pollution, in 1882 it is ·0277, and in 1883 ·030, showing that there is a decrease.

15,675. So the general run of these figures shows a slight oscillation, but no deterioration, in the general condition of the river?—Decidedly; there could have been no accumulation of contamination. Whatever the impurity of the river, whether the quantity of albuminoid ammonia is a perfectly true index of the absolute quantity of organic matter, or not, hardly matters, because we find that, whatever it is, it is relative. When dealing with the same description of nitrogenous matter as we find in sewage, we find there is no accumulation, that it is a little higher at one time and a little lower at another, but that, taking it year by year, there is no accumulation.

15,676. Now take diagrams Nos. 7, 8, and 9. I think those are to show the conditions of different parts of the river, the different depths from the surface?—On 27th July and 3rd August 1882 samples were collected at half-flood and half-ebb upon the surface of the water and two feet above the bed of the river at Blackwall, Woolwich, Barking Creek, and Erith; that is shown by Diagrams Nos. 7, 8, and 9, which are upon the same page. Diagrams Nos. 7 and 8 extend from Blackwall to Erith, and Diagram 9 from Crossness Point to Erith Causeway.

15,677. The result of these analyses generally is apparently that there is no very great difference whether from the bottom or top of the water?—No; the point is that the mixture of the impurities in the river, the sewage, or whatever it may be, is a tolerably constant mixture. If we look at Diagram No. 8, it will be seen that the quantity of albuminoid ammonia at Blackwall at half-ebb at the surface is high, and then it decreases to Woolwich, and that it is the same exactly at the Northern Outfall as the bottom sample, and a trifle higher at Crossness, and getting a little lower again at Erith. The lines cross one another, and there is no conclusion to be drawn from it except that the mixture is complete.

15,677*a*. Now, referring to Diagram No. 10, the effect of that is to compare the mid-stream with the shore flow upon the ebb tide?—On 24th August 1882, during three-quarter ebb, samples were collected 200 yards from either shore and in mid-stream off Crossness Point and Erith Causeway; they were taken to ascertain whether there was any difference in the character of the water flowing at either side of the river, and the practical result is that at Crossness Point it is exactly the same on either shore, rather better in mid-stream, and at Erith Causeway the mid-stream is still the best, but the differences are very slight indeed; there is no practical variation; drawn upon this scale, they look more important than they are.

15,678. Now I think we want to go back to Diagram No. 4, which we have skipped; that will show the samples taken upon the 31st August and 1st September 1882, taken at all periods of the tide?—Yes.

15,679. This is a diagram which will show the changes in the condition of the samples of water at that spot at those periods of the tide?—Yes.

15,680. And also with the chlorine dotted?—The chlorine follows the tide.

15,681. As one necessarily expected, the chlorine is lowest at low water and highest at high water?—That is so. On 31st August the river at low water, having received the sewage from the outfalls, was naturally at its worst, after two hours' flood its character was improved by the water from below. At high water it was at its best, and becoming worse at quarter-ebb. On 1st September, after the scour of the river by the exceptionally high tides of the 31st, which were 1½ inches above Trinity high-water mark, and which must have carried the impurities of the river a considerable distance down stream, the water was a trifle worse at half ebb than at a corresponding time of tide on the previous day. It was about the same at three-quarter ebb, and considerably better at low water, notwithstanding the sewage of the outfalls. As the flood came up, bringing with it a certain proportion of the polluting matters previously carried down, the impurity increased to a maximum for the day at high water (when it was less than at low water on the 31st), and at quarter-ebb fell again to one half.

15,682. Speaking generally, from all those analyses does it become manifest that the organic pollution of the Thames, speaking for the period of six years over which they extend, is practically constant, and not an increasing quantity?—That is so, as I have shown before. The figures at Woolwich would apply with slight variations to any other portions of the river; that is to say, at high water and low water, as the

case may be, there are variations, but the average result of it all is that it is very much the same during the period of six years.

15,683. Is that constant or practically constant quantity such a quantity as could be reasonably supposed to be either dangerous to health or a source of annoyance to people passing along the river or living upon its margin?—The various analyses which have been made of the Thames water show that the organic ammonia yielded by samples collected above Teddington Weir is only from half to a third of that in samples taken at Woolwich, so that, if we deduct the additional quantity of organic matter which the river receives in its downward course through the shipping, &c., it will be at once seen that, if the water at Woolwich and other points in the neighbourhood of the outfalls is contaminated by the Board's sewage works, it can only be to a trifling extent, an extent not greater than that present in ordinary London drinking water.

15,684. You say the ammonia yielded by samples taken of the water above Teddington, as compared with ·03, which one may take as a rough average of your samples all through, will be found to be about half to a third of that at Woolwich, that is to say, from ·01 to ·015?—Yes.

15,685. Then you have sources of contamination between Teddington and Woolwich, which add to that?—Yes.

15,686. Which would make it more than three times?—The difference between the quantity at Teddington and at Woolwich after deducting the quantity which we may reasonably conclude is due to the shipping, &c. is very slight.

15,687. If I remember rightly, that is clearly confirmed by Dr. Tidy's analyses?—Yes.

15,688. I think that the same result comes out from that, that the purity of the water in the neighbourhood of the outfalls is from two and a half to three times what it is where the people of London have it taken from to drink?—Yes, speaking roughly, not having the figures before me.

15,689. (*Dr. Stevenson.*) That is before filtration, you mean, as it comes over the weir at Teddington?—Yes.

15,690. (*Mr. Lumley Smith.*) Is that based upon these albuminoid ammonia investigations?—Yes.

15,691. I do not think Dr. Tidy at all based any conclusions upon that?—No, I do not know that he did.

15,692. (*Mr. Bidder.*) That concludes all the diagrams; then you have some tables; I believe you wish to refer to Table No. 5 on page 12?—Yes.

15,693. What is to be noticed in those samples?—That the water in the Victoria Docks, in Deptford Creek, Bow Creek, and Barking Creek, is on the whole worse than the water in the River Thames in mid-channel. *Mr. W. J. Dibdin.* 13 June 1883.

15,694. (*Chairman.*) Were these samples taken in the docks or in the river outside the docks?—One sample was taken inside the docks.

15,695. Was it taken near the middle or entrance, or the upper end, or where?—I think it was taken in the middle of the docks as nearly as may be. I do not know the exact point, but right inside the dock.

(*Mr. Bidder.*) The others, of course, are taken in the Deptford Creek at low water.

15,696. (*Mr. Lumley Smith.*) It would make a material difference at what part of the Victoria Dock that sample was taken?—I will let the Commissioners know that; there you get 0·066, which is twice as much as we get in the river water.

15,697. Take Deptford Creek and Bow Creek, both of which have feeders, they seem to indicate they are rather worse than the water of the River Thames?—Yes, that is so.

15,698. And you would say that that which feeds Barking Creek is very much worse?—In some cases, on March 14th, 1878, for example, it is ·081, and the average taken in the two years 1878 and 1882 was ·048.

15,699. (*Dr. Stevenson.*) Were the samples taken after there had been any storm outfall overflowing?—I cannot say that.

(*Mr. Bidder.*) I will make some enquiries about that.

(*Mr. Lumley Smith.*) I should like also to know the point where the samples were taken in Deptford Creek.

(*Chairman.*) Unless you have the position where those samples were taken, their value is diminished by, it is impossible to say, what extent; you had better, as the Americans say, locate the point of the collection of the water samples.

15,700. (*Mr. Lumley Smith to the witness.*) None of these samples, as I understand, were taken by you?—No, only one or two.

15,701. (*Mr. Bidder.*) I think you have taken some samples of what was coming into the river from other places?—As regards the sewage from sources other than the Metropolitan outfalls.

15,702. And the Chiswick ones?—That sample I took myself, that was the sewage; I have put forward no sample in any table, the collection of which I cannot prove.

Adjourned to Tuesday next at half past 12 o'clock.

---

# FORTY-FIRST DAY.

## Tuesday, 19th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

Mr. HENRY LAW called again; further examined by Mr. NORMAN BAZALGETTE.

15,703. (*Mr. Norman Bazalgette.*) Sir John Coode asked Mr. Law for the area of the Crossness section on the line D.D. (*To the witness.*) Will you give that?—I have taken that out for 1833 from the survey of Captain Bullock and Captain Burstal. The sectional area at low water was then 20,445 square feet. In 1861, from the survey of the Thames Conservators, it had been enlarged to 33,780. In 1864, from the survey of the Metropolitan Board of Works, it had already diminished to 28,770. From the soundings of *Mr. H. Law.* 19 June 1883.

*Mr. H. Law.*
13 June 1883.

the Metropolitan Board of Works in 1879 it had then been increased to 33,850 square feet. We have no soundings subsequently.

15,704. Are they all upon the same line?—Yes, they are all upon the line D.D. Then I wish to point out one matter with regard to the section put in by Mr. Mansergh. I would observe that the line at the bottom of this section, which represents the low-water area, does represent the low-water area in 1878 from the commencement as far as the line 5. W.; it also represents the same thing from 2. E. to the lower end of the section; but between the point 5. W. and the point 2. E. it represents the area in 1861 upon the north half of the river combined with the area in 1878 upon the south side, and therefore does not represent anything comparable with the other part of the section. But the whole red line is that which represents the area in 1878, and is therefore a continuation of the black line upon the other part of the section.

The witness withdrew.

Mr. William Joseph Dibdin called again; further examined by Mr. Norman Bazalgette.

*Mr. W. J. Dibdin.*

15,705. When we broke off upon the last occasion you were going through your various tables, explaining each of them. I think we broke off at Table No. 4; was that so?—Yes.

15,706. What does Table No. 5 contain?—The Commission will remember that we were obliged to pass Table No. 4 and go to Table No. 5, and so go to the end of the tables and come back to Table No. 4, No. 4 being put in this position for the convenience of the lithographer in putting it upon the paper. The next point we come to is the sewage from sources other than the Metropolitan Board of Works outfalls. Before considering this, with the permission of the Commission, I should like to go back to sample 232 on page 12, the Victoria Dock sample. But before passing to that, I beg to hand in the table of analyses of the London sewage which were referred to last week, when unfortunately the tables were not ready. (*The tables were handed in.*) Now No. 232, on page 12, represents a sample taken on March 25th, 1878. Some doubt was thrown as to the correctness of that sample, it being so long back as the 25th of March 1878; it is a sample I am in hopes of being able to prove the collection of before the Commission; but as there might be some little doubt about it, and as I have not yet been able to identify the collector, to overcome any objection upon that score, I had an additional sample collected yesterday morning at about half-past eight, about 100 yards inside the Inner Lock, 20 minutes before the lock gates were opened; so that that sample may be taken as a fair sample of the dock water. I found that the albuminoid ammonia yielded by that sample was ·059, the chlorine being 150 grains per gallon; so that the sample in 1878, as will be seen, yielded albuminoid ammonia equal to ·066, and this equal to ·059; showing that even now the character of the water in the Victoria Docks is much worse; it is more than twice as bad in many cases as the Thames water, taking the average of Thames water; it contains more than twice as much nitrogenous organic matter as the Thames water.

15,770. When you speak of the Thames, where do you mean, do you mean above or below the outfall?—I am speaking generally, because the condition of the Thames varies according to the tide and the rain water, and so on; but, taking the general run of the Thames water, not immediately in the line of the outfalls, but taking mid-stream samples, the Victoria Dock water contains twice as much organic impurity as the Thames water.

15,708. (*Chairman.*) What part of the river do you speak of?—The neighbourhood of the outfalls.

15,709. (*Sir John Coode.*) Where would that indicate?—Say, from Woolwich to down below Erith.

15,710. (*Chairman.*) Another thing is, what time of the tide would you speak of?—When I say "twice as much," I am taking the general average of both high and low water.

15,711. I suppose the Victoria Dock is supplied from the Thames, is it not?—Yes, it is.

15,712. And it has some contribution of sewage, I suppose, internally?—Presumably so, from the matter which appears in the docks.

15,713. What would that be from; would the men use their privies, or whatever they are, on board ship?—I presume so. I believe there are regulations in the docks that the men are not to use the accommodation usually provided on the vessels, but, beyond all doubt, they do not observe the regulations. At all events, this is the analysis and the actual result obtained from a sample of the water; wherever the pollution came from, there it is.

15,714. (*Sir John Coode.*) The same regulation would apply to what we may call the offal or waste in preparing the vegetables and meat cooked on board, and all that sort of thing?—I am not able to speak from personal observation with regard to that.

15,715. (*Chairman.*) I am rather at a loss to perceive the utility of this; if the same regulation does apply, what then?—It amounts to this, that, if the water of the Thames is so polluted as to have an injurious effect upon the health of those living upon it, surely the dock water would have the same effect.

15,716. (*Dr. Stevenson.*) Have you compared the water in the Thames at high water with the water in the Victoria Dock?—Yes. By turning to my samples in 1880 and 1881, taking 1880 first, which are given in Table No. 2, page 3, beginning at No. 25, and going on to sample No. 28, and every alternate sample after that, you will find the analyses of samples taken at high water off Woolwich Arsenal, and if you look at the column of albuminoid ammonia, you will find it varies; as, for example, ·021, ·033, ·025, ·034, ·028, and so on; the average for all the samples, one at high water and one at one hour after high water, being ·0286, or rather less than half that in the Victoria Docks.

15,717. (*Sir John Coode.*) That in the Victoria Docks being ·066?—·066; and ·059 by the sample collected yesterday. Off Woolwich Arsenal, again, on August 15th, 1881, will be found, on page 6, No. 95, a series of samples which were taken at one hour before high-water, one sample being taken in mid-stream, and one sample being taken vertically over low water mark; so they were taken just before high water, and may be taken as fairly representing high water. There it will be seen that the maximum upon any occasion was ·056, being an exceptional sample altogether; and four days afterwards, upon the 19th August 1879, the albuminoid ammonia was ·021. And, looking down the column, it will be seen that the average which is given at the bottom of this series, on page 8, was ·037 for that year, being the year in which the worst samples had been taken off Woolwich Arsenal, and then it was only ·037, whereas in the docks we have ·059 and ·066.

15,718. Were they taken year by year?—Yes, since 1878, with the exception of 1879, when we were engaged in the Mud Inquiry.

15,719. (*Mr. Norman Bazalgette.*) I do not know whether you have instituted a similar comparison for albuminoid ammonia between the average Thames water and the water found in Deptford and Bow Creek?—Yes. We come to Deptford Creek at samples Nos. 233 and 234, in Table No. 5, on page 12. On October 30th, 1882, the albuminoid ammonia was equal to ·040, and on November 1st to ·057, being an average of ·048. These samples were taken some little way up the creek at dead low water, so

that the water which was in the creek then was that coming down from the creek; it was not Thames water which had gone up and come down again, as it might have been if we had taken it at any other time of the tide. It was dead low water in the river. All the water had come out of the creek then, and a sample was taken of the water then flowing down the creek, a boat being taken up the creek as far as it could go.

15,720. (*Sir John Coode.*) What would be the population draining into Deptford Creek at the point above where the sample was taken?—That I am unable to say.

15,721. Is it large or small; it would depend upon that, of course?—I believe there are a number of factories which drain into it, and a good deal of land-water drains into it. Then you have Bow Creek. On April 3rd, 1882, a series of samples was taken off the Thames Ironworks, off Iron Bridge, off the Four Mills, and off Bow Bridge.

15,722. (*Chairman.*) Where is Bow Creek?—Bow Creek is just below Blackwall. The Thames Ironworks are situated at the corner of the creek.

15,723. Is it at the outlet of the Lea?—Yes, it is.

15,724. Then you have got lower down than Deptford now?—Yes. There the albuminoid ammonia is seen to be in the first ·042, varying to ·032, the mean being ·033, which, although much the same, is rather worse than the ordinary Thames water.

15,725. (*Sir John Coode.*) That is just half of the proportion in the sample that you have got from the Victoria Dock?—Yes.

15,726. (*Chairman.*) That is better than Deptford Creek, half the Victoria Docks, and worse than Jenningtree Point, which is No. 280?—Yes. A question was asked last week whether any overflows had taken place shortly before the samples were taken in Bow Creek on April 3rd. I may mention that the rainfall at Greenwich upon March 26th, 1882, was ·67 of an inch, and that no rain fell from March the 26th to the date of the collection, April 3rd, so there had been no recent overflow, even if there was an overflow upon that occasion, which I am unable to say. Then passing to page 13, we come to Barking Creek, where we have samples taken in 1878 on different dates, and on April 12th, 1882, when a similar series of samples was taken to those in Bow Creek. There we find that on March 14th, from a sample taken mid-way between the outlet and the town of Barking, two hours before low water, when the creek water was coming down, we obtained albuminoid ammonia equal to ·081. On the 22nd, two hours before high water, it was ·057, showing that when the river water was going up, having mixed with some of the creek water, the mixture of the creek and river water was much worse than the river water itself. On November 16th, 1878, in a sample taken some distance from the mouth of the creek at dead low water, when there was a quantity of tarry matter coming down in the creek water, floating upon the surface to such an extent that it was not only perceptible to the eye, but the odour of the tar was very distinct in the atmosphere, even on the deck of a tolerably good-sized steamer, in that sample the albuminoid ammonia was ·051. That was undoubtedly a sample of Barking Creek water without much river water; that is shown by the quantity of chlorine, which is 2·88. Now the water shown at the mouth of the creek is 153·0 of chlorine just at half ebb, so there could not have been much sea water in that sample of November 16th. When I say "sea water," I am speaking of it as a mixture of sea and river water. If there had been no river water, there could have been no sea water. Then following down the samples, upon April 12th the albuminoid ammonia went from ·034 to ·038, the total average for the samples collected at Barking Creek upon the different dates being ·048, or considerably higher than the river water.

15,727. (*Chairman.*) Is it conceded that albuminoid ammonia, if any, is a dangerous material?—I think so. The other side have used it in their evidence.

(*Mr. Balfour Browne.*) It is certainly not conceded at all; it was used by two of the chemists who gave evidence before you, and they both said that it was useful up to a certain point, but not a reliable or an accurate test of the impurities in the water.

(*Chairman.*) Does Mr. Dibdin's evidence differ from that which was given upon your side?

(*Mr. Balfour Browne.*) Yes, and considerably in many respects.

(*Chairman.*) Does it differ in that you make a greater quantity of this objectionable matter?

(*Mr. Balfour Browne.*) Yes, we make it a greater quantity, and we say we have taken it by processes which are reliable; whereas we say the albuminoid process is not a reliable or an accurate test.

(*Witness.*) I think we shall be able to show, both from my own evidence and from the evidence of the chemists who are to follow me, that this is a very reliable test, and a test reliable not only for the purpose of telling whether there is a greater or less quantity of sewage in water, but a test which is used by chemists almost universally as a guide in telling them the quality of ordinary drinking water, not merely as a test for sewage, but as a test of a perfectly pure water compared with this; and if it is so delicate a test, and is used so universally, not only in England, but elsewhere, and is generally admitted as an indication of relative purity, surely, your Lordship, I think, will agree with me that we are entitled to use it in estimating the value of such a water as the Thames.

15,728. (*Chairman.*) I suppose some albuminoid ammonia in water would not make it deleterious?—It might, undoubtedly, or, on the other hand, it might only be a small quantity present from vegetable contamination. In fact, I think I am right in saying there is hardly such a thing known as a sample of water which will not yield a more or less quantity of albuminoid ammonia. Even if we take pure, distilled water, by which I mean ordinary distilled water, and treat that in the same manner as I treated this, we have a quantity, not a large quantity, but a trace, a very small quantity, of albuminoid ammonia; we actually get it there. If we take water containing a slight contamination, we get a little more albuminoid ammonia; as the character of the water decreases, the quantity of the albuminoid ammonia increases, until from, perhaps, 1000th part of a grain we come to sewage, which will give us, in some cases, from one to two grains; ordinary London sewage, as I shall show from my analyses, containing something less than half a grain. So that we have a very wide range; indeed, I think the Commission will agree with me, when they have heard the whole of the evidence, upon this point, that this method of analysis is an exceedingly delicate and reliable one, not one which gives, as I stated last week, the actual amount of organic impurity, but the relative amount of organic impurity.

15,729. (*Sir John Coode.*) I think I asked you upon the last occasion whether there was any other method or any better method?—There are several other methods, for example, the estimation of the organic carbon and the organic nitrogen. There is a method of estimating the quantity of oxygen absorbed from a solution of permanganate. I think Dr. Tidy stated in his evidence that that method is not to be relied upon when dealing with sea water containing a quantity of chlorides; but I believe that other chemists, who have studied this question very carefully, have found methods of conducting the process which do give them reliable results in dealing with water containing sea water.

15,730. (*Mr. Balfour Browne.*) That is the permanganate process, is it not?—Yes; but when we are dealing with a mixture of sea water, river water, and sewage, and goodness knows what besides, I am certainly of opinion that there is no better method

*Mr. W. J. Dibdin.*

19 June 1883.

known which can be used as a guide in estimating the quantity of nitrogenous organic matter in the water.

(*Mr. Norman Bazalgette.*) Perhaps, in answer to your Lordship's question, you will allow me to read an answer from the evidence of Professor Heaton upon the subject; he was a chemical witness called by the other side. He was asked, at question 11,357, "Will you tell us the particular constituents for "which you tested?" and his answer was, "Those "which appeared to us to be most important were "two in number, first, the examination of what is "called albuminoid ammonia, and, secondly, the deter- "mination of dissolved oxygen. (*Q.*) Those are the "two important ones? (*A.*) I do not say that they "are the only important ones, but we regarded them "as very important for our special purpose."

15,731. (*Dr. Stevenson to the witness.*) Referring to Dr. Heaton's evidence, which was given upon the 7th of March, he gives certain tables of albuminoid ammonia and other constituents; have you compared your own results with those obtained by Professor Heaton, and drawn any conclusion?—No; for this reason, that Professor Heaton stated, and I think his analyses show, that his method of operation was different from mine in that he included a great quantity of suspended matter in his albuminoid ammonia.

15,732. (*Mr. Norman Bazalgette.*) I was going to put a question which would have made that a little clearer. I was going to ask the witness whether he had imitated Professor Heaton's example and filtered his sample?—No, that is not so; Professor Heaton did not filter his samples, but in all my samples the mud was allowed to settle and the clearer water drawn off for analysis.

15,733. (*Dr. Stevenson.*) Your sample did not represent the whole of the albuminoid ammonia then?—The whole of the albuminoid ammonia in solution. The question of the suspended matter is a separate question, because it is evident, if you take a sample of the Thames water immediately after a steamer has passed by, you get a certain quantity of mud mixed up; and if you include that mud in your water and make an analysis of it, you will get altogether different results from what you will if you take the clear water alone. In the former case the albuminoid ammonia will form a measure, not of the soluble organic matter, but of the amount of solid impurity present or stirred up.

15,734. Your samples represent clear water, and Professor Heaton's represent muddy water?—Mine represent the water as you obtain it after allowing it to settle down for, say, 24 hours. Now Professor Way put in a number of analyses of samples which were taken upon the 14th and 22nd of September, and in those he gave estimations of the quantity of albuminoid ammonia; and I think, looking at it roughly, because Professor Way has taken his proportions in parts per 100,000, and I have taken mine in grains per gallon, but looking at the figures, they are practically the same as my own.

15,735. (*Mr. Norman Bazalgette.*) Then you and Professor Way are agreed pretty nearly in your figures?—Decidedly so. For instance, upon September the 14th samples were taken at Teddington by Professor Way, in which the albuminoid ammonia was ·13 and ·12. If we go to Barking upon the same date, we find that the albuminoid ammonia was ·21 and ·24, or only twice as much as in the water taken up at Teddington; and that is confirmed by my own analysis that the albuminoid ammonia is from two to three times as much at Crossness. And upon the same days he has two or three times as much. In the first sample he gets less than three times as much as at Teddington, and in the other only twice as much as at Teddington, figures which agree very closely with those which I have laid before the Commission.

15,736. (*Dr. Stevenson.*) Were Professor Way's analyses made with filtered water?—I cannot say, but I believe he treated them in the same way as I did, namely, that the suspended matter was allowed to settle. In fact, I think he must have done so, looking at the results, otherwise the results would have been very much higher. Now on page 13 of my tables, at Nos. 246 and following, a number of analyses are given of sewage from sources other than the Metropolitan Board's outfalls. Perhaps this would be the fitting time at which to call your attention to the tables of analyses of London sewage, which I have in the second book of tables which I have handed in. Turning to page 6, at the bottom of the page, I give the average of the samples from both outfalls which were examined for albuminoid ammonia, the samples being collected in the method I stated last week, and at the times shown in the tables. Taking the average of the samples collected from both outfalls during the months of March, April, and May, the albuminoid ammonia seems to be ·383; this is at page 6. In these tables of figures you will see that the first sample on page 1 was taken at the southern outfall on March 23rd and 24th, 1883. They were all taken during the months of March, April, and May from the two outfalls. I may tell the Commission the object of these tables. I do not wish you to go through all these figures; it would be unfair to suggest it. I simply wish to call your attention to my results. I may state the object at once for which these analyses were made. The Commission will remember that there was a considerable controversy during the evidence that was given on the other side as to the quantity of suspended matter in ordinary London sewage, and we had some very big figures put before the Commission, and the analyses which had been previously made to ascertain this point were called into doubt. In order to settle this question as far as possible, I had this series of samples collected, and the result of it all is given in the third line of the average results at the bottom of page 6. Taking the average of samples from both outfalls, we find, speaking of albuminoid ammonia, that the albuminoid ammonia yielded by these samples is equal to ·383. At this point I might correct a figure I gave last week. I said ·366; that was the southern outfall, the average at both the outfalls being ·383. The average quantity of suspended matter in sewage being 27·39 grains per gallon. Dr. Tidy, in his evidence, stated that he believed the average quantity of suspended matter in London sewage, taking wet and dry weather together, would be nearer 50 grains. The Commission will therefore see at once that it is a very material question, as to the quantity of solid matter discharged into the river, whether we discharge 27 grains into the river or whether we discharged 50 grains.

15,737. (*Chairman.*) By "grains" you mean grains in weight, do you not?—Yes; I have mentioned before that, if we treat the ordinary filtered water supplied by the London Water Companies, we may get ·005 or ·006 or ·007 of a grain of albuminoid ammonia per gallon, but if we take the sewage, it is ·383. In some cases it is very nearly one grain, ·8 or ·9 of a grain per gallon. And sometimes the sewage, from the increase of rainfall, is weaker, but ·383 represents the average, the London filtered water being ·005 or ·006. Now, having those figures for comparison, I go to sample 246 upon my 5th table, page 13, where we have a Chiswick sample, taken on the foreshore at 12.45 p.m. on August 16th, 1882. This was a sample of sewage collected by myself upon the foreshore at low water. As we were proceeding up the river, we noticed that the sewage was being discharged from the outfall at Chiswick. It came down over the lip of the sewer, and ran down the foreshore, and so into the river. We were unable to get a sample of the pure sewage, so we got a sample of the mixture of sewage and water, as it was running into the river, taking care to get it as nearly pure sewage as we could. But this Chiswick sample gives us albuminoid ammonia equal to ·31, which is only a trifle less than we get at the Metropolitan Board of Works outfalls. So that, if the chemists upon the other side have said, as I believe they have done, that they have found sewage up as far as Chiswick, I am not at all surprised.

(*Chairman.*) I thought we had given up Chiswick.

(*Mr. Norman Bazalgette.*) I think your Lordship drew the line of the influence of the river upon health at Rotherhithe.

(*Witness.*) The only object of this is to show that, if traces of sewage have been found at Chiswick by the chemists upon either side, there is no reason why they should not have found them ; and, that being so, I would leave the upper river and go to North Woolwich. The same table, at No. 247, gives us a sample from the North Woolwich outlet, which is just below the pier at North Woolwich, near the gardens there, so that, if anybody crossing the river at low water found a smell arising when the paddles of the steamer were stirring up the mud, it is not surprising. We find the sample taken on October the 16th, 1878, at 9.40 a.m., gave us albuminoid ammonia equal to ·217, and that at Beckton Gasworks upon the same day the sample gave us albuminoid ammonia equal to ·135.

(*Chairman.*) But will you tell us your results instead of giving us the figures in detail.

15,738. (*Mr. Norman Bazalgette.*) Does that determination as regards the Beckton Gasworks show that the gasworks discharge something other than gas drainage?—Yes. Then we will pass to a more interesting subject, namely, the discharge from the sewer at Erith at low water when the mud is all uncovered.

15,739. (*Dr. Stevenson.*) Could you give us the volume flowing from these places?—The discharges vary considerably. At the Beckton Gasworks upon one occasion there was a considerable quantity being discharged.

15,740. (*Chairman.*) Did you take your Erith sample from the pipe discharging immediately into the river?—Not discharging into the river, but discharging on to the foreshore.

15,741. And you found it exceedingly foul, did you?—I did.

15,742. Unless you can give the comparison of the volume that was discharging into the river as compared with the volume of the river itself, what does it prove; we know that sewers are foul?—My object is to show that these samples were exceptionally foul, far fouler than anything obtained from the Board's or other sewers, except at Erith. My evidence goes to prove that it is foul, and that it is discharged on to the foreshore when that part of the foreshore is not covered with water, and that under the heat of the summer sun even a small quantity of that exceedingly concentrated sewage may give rise to what have been described as stale water-closet odours. The quantity of albuminoid ammonia yielded by this sample was equal to 3·70 grains per gallon, and I may say that the odour from that sample was the worst I ever smelt from any sample I ever analysed. This was taken at a point off the flour mills just above the Causeway; and from personal inspection I can state to the Commission that any question of liquid sewage is not to the point with regard to these Erith cases; but that from a slaughter-house adjacent there was actually lying upon the beach—upon the hard stones and gravel above the soft mud—slaughter-house refuse, guts and gall bladders, and so on, solid sewage refuse and various other matters, and the atmosphere upon a comparatively cool day, at that spot (and there were boats and men working just about there), was exceedingly obnoxious.

15,743. (*Mr. Norman Bazalgette.*) Was what you saw quite sufficient in your judgment to account for the complaints which we heard from the Erith people about the smells at low water?—A very great deal more than sufficient. I could not have believed any such state of things existed anywhere along the banks of the Thames, and when I saw that I was exceedingly surprised, it was far more than enough to account for anything I have heard.

15,744. (*Chairman.*) You do not refer so much to the general bulk of the pollution as to its offensiveness at that particular point?—As far as the bulk of the pollution goes, it would be a mere drop in a bucket if put into the river in a proper manner, but, lying in a heap of solid matter, it is exceedingly offensive.

15,745. (*Mr. Norman Bazalgette.*) I believe you have made determinations over a considerable period—over the last six years—for chlorine in Thames water in the neighbourhood of London Bridge?—Not only near London Bridge, but elsewhere in the river; but in the samples of Thames water at London Bridge which I have examined, the chlorine has at no time exceeded five grains per gallon.

15,746. What inference do you draw from that?—The inference I draw from that is that the quantity of sea water which comes up to London Bridge is exceedingly minute ; and I may say at once that the two occasions upon which I obtained four grains per gallon are given on page 9 of volume 1 of my tables at Nos. 187 and 188. On March the 12th, 1883, at No. 187, on the surface and 20 feet below the surface, at 4.45 p.m., two samples were taken, and also on March the 10th two samples were taken ; on Saturday and Monday, when exceedingly high tides prevailed in the river, so much so that people barricaded their walls for fear of having an overflow, and it will be seen upon the first day (the Saturday the 10th), when the tide came up the chlorine was 2·1 at the surface and 2·2 20 feet below the surface. On the Sunday the high tides prevailed again, and also on Monday the 12th, when the amount of chlorine in consequence of the high tides had risen to 4·1 and 4·2 grains per gallon, which is very different from the 140 grains which have been put in by the other side. This is my experience. In exceptionally high tides and in exceptionally dry weather the quantity would be higher.

(*Chairman.*) The object of this is to show, is it not, that the sea water does not come up to London Bridge, and does not bring sewage with it in great volume, and that the river at London Bridge is not poisoned?—Yes.

15,747. (*Mr. Norman Bazalgette.*) Now will you pass to the suspended matter, and tell me what steps you have taken to arrive at a conclusion with regard to the suspended matter in the London sewage?—The results of the analysis are in volume 2, which I have put before the Commission, that is to say, the total quantity of suspended matter in the London sewage in April and May of this year, as shown in the tables, is equal to 27·39 grains per gallon.

15,748. I believe the tables show that you have taken the effect of the rainfall into consideration?—Yes, the rainfall is shown in the column headed "Rainfall at Greenwich."

15,749. (*Prof. Williamson.*) Is that the average made up from any determinations of different states of rainfall applying to the quantities, or how is it obtained?—It is obtained as shown in the tables ; we took samples at every four hours at the outfalls. In the case of the southern side, all the sewage runs through one long length of sewers down to the outfall, and then passes through the pumps. We took a sample just as it came from the pumps, so that it was thoroughly mixed up, that was at 6 o'clock, and then another sample at 10, and so on every four hours. Now upon the northern side the sewage runs down to the outfall through three sewers, we therefore took a sample from the lip of each sewer at one time, and mixed them together, and that would be the sample, say, at 6 o'clock, and we should do the same thing at 10 o'clock again as before, and every 4 hours. The hours of collection are given with the rainfall at Greenwich.

15,750. The quantity of rainfall and sewage representing each determination, or how?—No, the figures show the quantities present in each gallon of the sewage, the quantity would vary with each quantity of sewage discharged.

15,751-2. So that this does not profess to represent what would be the average; but you collected all the sewage and mixed it?—I think it does represent the average as nearly as we could possibly get it.

*Mr. W. J. Dibdin.*

19 June 1883.

15,753. Before it could do that, you must know how much of each quality there was?—I am afraid it is a matter about which there is considerable difficulty. I have tried to do the best I could.

(*Mr. Norman Bazalgette.*) Will you next state what you have done in order to ascertain whether there has been any considerable variation in the character of the mud in the neighbourhood of the outfalls during the last few years.

15,754. (*Chairman.*) Would you mind first of all telling us the result which you have found, and your conclusion from your experiments?—I have found generally that there is no practical difference whatever in the composition of the mud from the various banks in the neighbourhood of the outfalls between the years 1879 and 1883. I have had samples taken in precisely the same spots as those collected in former years, analysed as nearly as possible in precisely the same manner. The results are shown in my table, and the general result is that there is a composition there which is exactly the same as it was.

15,755. How many years ago was that?—Between the years 1879 and 1883.

15,756. (*Chairman.*) It seems to me that that is not a momentous question. You do not know, I suppose, what was the composition of those banks in the same places before the outfalls, do you?—I am afraid I do not.

15,757. Have you made a comparison between those banks and banks not subject to the influence of these outfalls; for instance, a bank of mud above bridge, now?—In the present instance, I have not. That was so fought out in the arbitration, and such a number of analyses were then put in, showing that the composition of the mud in the River Thames throughout its whole length is fairly uniform, that, that question having been settled, it was thought if we could show now that the banks in the neighbourhood of the outfalls have not increased in polluting matter, and that the composition of these banks is the same now as it was then, we should have answered that question.

15,758. That is to say, it was then shown that the mud in the neighbourhood and under the influence of these outfalls was the same as the mud of other parts of the River Thames, and you show that it has not got worse now?—That is so; that is the pith of it.

15,759. (*Mr. Lumley Smith.*) The witness must not take it that that was admitted on all hands in 1879?—That was the distinct finding of the arbitration.

(*Chairman.*) But the result of the arbitration had nothing to do with the composition of the banks, had it?

15,760. (*Mr. Norman Bazalgette.*) There was, I think your Lordship will find, a finding of the arbitrator upon that very subject, viz., the composition of these very banks in respect to sewage. (*To the witness.*) I think you have also taken samples of Thames water off Erith, for the purpose of determining the amount of suspended matter in them?—Yes, that is page 14. But on the same page samples are given of the mud which would be skimmed, as it were, off the immediate surface, and mud taken from 6 inches below the surface, and there I find that the sample upon the immediate surface, as will be found from the analysis, taking the quantity of mineral matter, contains rather less mineral matter, that is to say, rather more organic matter, than what is contained in the sample from 6 inches below; in other words, it is rather more impure. But that is taking it upon the immediate surface, as you would skim it off with the point of a penknife. It was taken to see whether there was any difference in the mud, and the difference is shown very distinctly, the sample from 6 inches below being of the same composition as the ordinary banks of the Thames, and the sample upon the immediate surface being, as I say, a trifle worse; but not even then being anything like sewage as shown by the analysis. The quantity of organic matter in the sewage mud from the floor of the reservoir, being 34·68 per cent., that in the mud upon the immediate surface at Erith Pier is only 14·28 per cent.; and, as the estimation of the nitrogen shows, the organic matter, although considerably less than in sewage—a difference of 14·28 per cent. against 34 per cent.—the nitrogen in the organic matter in the mud is only 4·69 per cent., against 5·34 per cent. in sewage.

15,761. (*Chairman.*) What is the bulk when you say 34 per cent. 34 per cent. of what?—Of the dried mud from the sewage. A sample of that portion of the suspended matter in the sewage which settles to the bottom of the reservoir is taken and the water evaporated off until the sample is perfectly dry, and then it is burnt, and we find that the loss on ignition is 34 or nearly 35 per cent.

15,762. (*Chairman.*) Do you mean 34 per cent. of the suspended matter?—No. If we take the whole suspended matter in the sewage, we shall find upon my other tables that the organic matter is equal to 54 per cent.

15,763. Take a gallon of water, what percentage of suspended matter is there in it?—That I have not worked out. This is the dry material.

15,764. It is 34 per cent. of the dry matter that you are speaking of?—The organic matter in the mud deposited in the reservoir is 34 per cent. of the dry matter.

15,765. (*Mr. Norman Bazalgette.*) I believe you have been at some pains to take a sample of mud from a tidal river which was free from all possibility of pollution with sewage?—I have. Having the opportunity, I obtained a sample of mud from the River Fitzroy in Queensland. I wanted to obtain a sample of water in which there should be no symptom of pollution. The town of Rockhampton is situated below the point at which the sample was taken, and furthermore it is a non-sewage river, because Rockhampton is a privy town essentially. The sample was sent me by my brother who is in Queensland.

15,766. I believe you have been there yourself?—Yes, I have resided in Rockhampton some little time. I know the river perfectly well, and I know that it is free from all sewage contaminations. I find that the mineral matter present in the dried mud of this sample is 94·8 per cent. It is only a little more than what you have in the Thames, where it is 85·72, the volatile matter in the Queensland sample being 5·2 per cent. The estimation of the nitrogen and phosphoric acid per cent. of dried mud gives 2·37 and ·24 respectively, showing that the amount of organic matter as represented by those figures is less than we find in the Thames mud, but not much less.

15,767. Is it less by a half?—No. If we take samples 14 to 20, we find the average percentage of nitrogen is 2·7. Taking the average of samples 3 to 12 in 1879, we find that the nitrogen in the organic matter is 3·48, and the same samples in 1883 give 3·6; whereas, if we take the Rockhampton sample, it is 2·3.

15,768. (*Chairman.*) What does it come to; that their river is better or worse than the Thames?—It shows that that river, which is a perfectly pure one, contains organic matter to nearly the same extent as the Thames does.

15,769. Does not that prove too much, because it would go to show that there is no organic matter in sewage?—No, certainly not, because we get 5·2 in the Fitzroy mud. There is very little difference, that is what it comes to.

15,770. (*Mr. Norman Bazalgette.*) Does it show this, that the organic matter which is present in the sewage does not get into the mud?—Yes, it does to a certain extent, and it does show that to a certain extent the mud is polluted, but to such a small extent as to make no appreciable difference.

15,771. I believe that you have taken some pains to ascertain the temperature of the water at various times?—Yes, I have inspected the river upon a number of occasions, having visited the whole length of what may be called the sewage zone, that is from

Greenwich to Erith and Purfleet. During the summer of last year I was frequently upon the river, and although the temperature of the water upon some occasions went nearly up to 70 degrees, yet the odour from the river water was nothing more than you would find either down at Southend or up at Teddington. In fact, it is not noticed until you take a small jar or vessel half full of water and shake it violently, then, on smelling it, there is what his Lordship has described as a sedgy odour, that and nothing more. Anything which would indicate sewage I have never noticed, unless we were in the sewage line. When we were following the sewage down from the outfalls, it follows the figures of analysis in the most wonderful manner, the sewage odour rapidly disappears, and even on shaking up the sample of water you get little more than the sedgy smell which you get in any river water.

15,772. Upon the numerous visits you have made to the river, have you noticed the smell of the factories?—Yes, I have noticed it very strongly indeed. Upon the numerous occasions when I have been down the river, the odour of the factories has been very strong. I have never been down the river but what the smell from one or other of the factories has been very powerful indeed. There are numerous manure and chemical factories situated on both sides of the river, and as the river winds about, whichever way the wind blows, you are bound to have the odour from some of these works, you cannot get away from them, and at times the odour from the works is extremely nauseous. I can easily understand the evidence which has been given by fishermen upon the river that the odours are extremely unpleasant, but those odours come from the factories and not from the river water. I have been down the river frequently in the summer time, and I have tried to isolate myself from the Metropolitan Board of Works view of the case, and to see what I could find as an independent individual, and I can conscientiously say that I have never been able to find any odour from the water except near the outfalls. When you are in the line of the outfalls you do find a smell from the outfall sewage, but that soon disappears as you follow it down, and upon a cold windy day you hardly notice it even when you are at the outfalls; but as you get down further by the works you notice a nauseous smell from the factories.

15,773. (*Dr. de Chaumont.*) You stated that the difference between the amount of organic matter as represented by nitrogen in the Queensland sample, compared with that of the average of the Thames mud, was inappreciable?—It is not put in the tables, but if you will insert after sample 20, and between that and "Erith Pier," the mean of samples Nos. 14 to 20, you will see what I mean. The mineral matter present is 89·52, this is excepting sample No. 17, which it will be seen is a sample of fine sand and coal dust, and could not be called mud. Mean of volatile matter 10·48, nitrogen per cent. of dried mud ·314, nitrogen per cent. of the volatile matter 2·97, and the phosphoric acid ·487.

15,774. Even then you will find the volatile matter is twice what it is in the Queensland sample, that the nitrogen per cent. of the dried mud is 150 per cent. higher?—The indication would be the nitrogen per cent. of the volatile matter, which is 2·37 against 2·97, while, if you take sewage, it is 5·2. Now I admit at once that in the mud there is a certain quantity of organic matter present; but, considering one is a pure natural river with comparatively no traffic upon it, no refuse from boats or barges and so on, and that the total quantity of volatile matter is less, the nitrogenous matter in the Rockhampton mud would naturally be less. Furthermore, we must bear in mind that the mud of the Thames contains a number of worms, in fact, everybody admits that all along the Thames there are worms, you cannot take a sample along the Thames without finding worms and minute infusorial life, which exist to a very great extent, so much so as to affect analyses; and in estimating the nitrogenous constituents of the organic matter we ought not to neglect the fact that animal life does exist in those samples, so that, if we deduct the amount of nitrogenous organic matter which we find by reason of the existence of these organisms, there is very little left to come from the sewage.

Cross-examined by Mr. Lumley Smith.

15,775. I understand that you have based the greater part of your calculations with regard to the pollution of the Thames upon the consideration of the albuminoid ammonia?—Yes, I have.

15,776. I believe you are a disciple of Mr. Keates upon the subject, are you not; he did the same thing?—Yes, and many of these analyses, as I think I have stated, were made by myself under the immediate direction of Mr. Keates. I was working with him during some part of this time.

15,777. I was going to ask you whether that process which is called "Wanklyn's process" has not of late years been given up by a great number of chemists?—Indeed not. I have heard of its being given up by one or two, but the great majority of chemists still use it.

15,778. When you say "the great majority" still use it, it is a very rapid and easy way of getting at some result, is it not?—It is a rapid and easy way of getting at a result, but not in all cases a reliable result. To obtain accurate results, and results which will be strictly comparable, requires very great care. If you adopt a rapid and easy mode of doing it, you may get any result you like, as you may with any chemical process.

15,779. I believe the opinion of chemists is divided upon this subject?—There are a good many who still use this process.

15,780. And a good many who do not?—And possibly a good many who do not.

15,781. I believe Dr. Frankland gave it as his opinion that it was not to be relied upon at all. It does, in fact, give you no clue as to what the albuminoid ammonia comes from; you cannot tell what the source is from which it comes when you find the albuminoid ammonia?—There are very few processes which will give you the actual composition of the organic matter in a sample of water; if you could find one which did, it would be an extremely valuable process; but I know of no such.

15,782. It gives you no notion of the source from which the albuminoid ammonia comes, does it?—I think it does in this way. If we take sewage, and treat it by this process, we get a certain result; if we take a mixture of water with sewage, and treat it in the same way, we get a certain result, and we are fairly entitled to say the thing is reliable to that extent.

15,783. You stated it as your opinion the other day that the albuminoid ammonia is now taken as an index of the amount of putrescible nitrogenous organic matter; that was so, was it not?—Yes, that which may be in a putrescent condition, or likely to become putrescent; that is, as I stated, nitrogenous organic matter, whether it is in a putrescible condition or not.

15,784. Could you venture to say that it did not give any index of non-putrescible organic matter?—It does not take into account the carbon; it takes only into account the nitrogen.

15,785. Is it not the fact that a great many things yield a great deal of albuminoid ammonia?—No doubt it is a fact, but it depends upon how you treat them, and what process you adopt.

15,786. Then a great deal of albuminoid ammonia might come from matters which were non-putrescible, and not likely to become putrescible?—Yes, that is so.

*Mr. W. J. Dibdin.*

19 June 1883.

15,787. I will give you a few examples. I am told that some bodies yield about half their nitrogen as albuminoid ammonia, is that not so?—Yes, it is.

15,788. And some yield the whole?—Yes.

15,789. Some yield half, some two thirds, and some one third, and some a quarter?—Yes, that is so.

15,790. And some none at all. Some which have nitrogen yield no albuminoid ammonia at all?—I believe there are some; I cannot say; I do not know it from actual experiment.

15,791. I suppose uric acid, for example, is a matter which goes into the river in the form of urine?—One would think so.

15,792. Is it not the fact that uric acid is a thing which yields very little or no nitrogen as ammonia?—I cannot say that, I have not made the observation.

15,793. So that what I put to you is this: there might be a vast quantity of urine in the river, although it would show no albuminoid ammonia?—That raises the question of the free ammonia.

15,794. But would you confine yourself to the albuminoid ammonia?—You are asking me about things which I cannot confine to albuminoid ammonia.

15,795. But I have your opinion that uric acid yields little or no nitrogen as ammonia?—I never tried it.

15,796. Take urea; is it not the fact that that yields no nitrogen as ammonia at all?—I have not made actual experiments upon the urea.

15,797. I have pointed out to you that there may be in the water elements of pollution which may yield no albuminoid ammonia?—There may be.

15,798. May there not be on the other hand a great deal of albuminoid ammonia which results from causes which are quite independent of sewage pollution, are you able to tell me that?—There may be, but in the case of the Thames I do not think there are.

15,799. Have you analysed or seen an analysis of any water of the river Shannon?—I have not.

15,800. The Shannon is a very peaty river, is it not?—I do not know that, I am not acquainted with it.

15,801. Is not peat a thing which would yield a vast quantity of albuminoid ammonia?—It undoubtedly would yield a vast quantity of albuminoid ammonia, but we are not dealing with the river Shannon or a peaty river.

15,802. I am dealing with Wanklyn's process, and I am asking you whether you may not get a great deal of albuminoid ammonia in water where there is no sewage?—You may under exceptional circumstances, but now we are dealing with the Thames, and the Thames is not under exceptional circumstances.

15,803. I am asking you whether you may not find a great deal of albuminoid ammonia in a river water where there is no sewage?—You might under exceptional circumstances.

15,804. Peat will produce it to a considerable extent, will it not?—Yes, it will.

15,805. And other matters will do it?—Peat will yield a considerable quantity of albuminoid ammonia, I believe.

15,806. Is not the result of it this, that the mere fact that albuminoid ammonia is found in water does not prove whether it comes from sewage, or whether it comes from peat, or what it comes from at all?—Not in all cases, decidedly not.

15,807. Is it not the fact that it varies, as one of our witnesses said, most capriciously in different parts of the river?—If you simply take the figures without any consideration of the circumstances, it does vary considerably; but if you consider the time of the tide, the height of the spring or neap tide, and the rainfall, and so on, you will find there is nothing capricious about it.

15,808. It wants a good deal of consideration, does it not, in order to get at the conclusion you want to get to?—You have to study the whole of the surrounding circumstances. At first it seems as if you could get no definite opinion from it at all, it all seems as if there were no order and regulation in the thing whatever, until, after making a series of examinations, you become acquainted with various surrounding circumstances, and it then becomes as clear as can be.

15,809. It comes to this, that at first sight your samples show no plan, and no order, but that after consideration you can evolve a theory out of them?—It shows at first sight that the river is not polluted with sewage or anything to such an extent as to cause a nuisance, and, independently of chemical analysis, common observation shows the same thing.

15,810. You are wandering away from the result of your previous answer. At first sight it shows that there is no order and no plan in the result of your observations?—At first one does not know why it is that if one takes a sample of water from Woolwich upon one day we get perhaps albuminoid ammonia represented by 20, on another day we take a sample and get perhaps 30, and we cannot perceive the reason of the variation; but, whatever the variations are, the impurity in the water does not approach sewage at any time or anything like it.

15,811. That is a matter of argument?—It is a matter of actual observation and fact.

15,812. Having stated what are the results you arrive at, is it not the fact that most chemists are giving up the Wanklyn process?—No, it is not the fact.

15,813. Have you tried the combustion process at all?—I have tried it, but I have not generally adopted it, it is one that occupies a considerable amount of time.

15,814. And the other is easy and quick?—The other is easier and quicker, and I believe is more reliable.

15,815. Many chemists adopt the combustion process, do they not?—I do not know. I believe they do.

15,816. Take Dr. Mills of Glasgow, for example?—I daresay he does.

15,817. And Dr. Odling?—Many chemists use it, but I believe that it is open to so many sources of error that it is hardly worth while adopting it.

15,818. Now you found that you had to take 181 samples, had you not, before you could evolve any theory out of it?—No, a single sample would have done that.

15,819. But you have already told us that a single sample would have left you very much in the dark?—I am speaking of river water; but, whether it is river water or sewage or anything which fluctuates in its character day after day and hour after hour, an assumption based upon a single analysis may be right if you happen to hit upon a mean sample, but if you get an exceptional sample, your result must be fallacious.

15,820. May I take it that in your results of albuminoid ammonia in sewage you find very great fluctuations?—Undoubtedly.

15,821. You did your best to prevent their fluctuating more than you could help, because I see in your volume 2 you took three samples and mixed them together. I find on the first page "Mixture of three "samples from pumps taken at 6 p.m., 10 p.m., and "2 a.m." Why did you mix the three samples?—Because it would be impossible to do the work otherwise without a large staff of assistants, that is to say, if all these were to be examined separately. If we were to take a particular sample at any time, we might have a strong sample or a weak sample of sewage, according as that might represent day or night sewage.

15,822. The result of mixing three samples together at intervals of four hours is that you never get a strong sample?—Undoubtedly you do. You get fair average samples.

15,823. You never get a strong sewage over eight hours?—Undoubtedly you do.

15,824. Then why do you mix them up? If 6 p.m. would be strong sewage from any particular pipe, then 2 in the morning would not be, would it?—No, it would not be so strong.

15,825. Is not the result this, that you are always diluting your specimens?——

(*Chairman.*) He is strengthening his 2 o'clock specimen.

15,826. (*Mr. Lumley Smith.*) It never gets either very strong or very weak?—The next samples are taken at 6 in the morning, 10 o'clock in the day, and 2 in the afternoon, and I have mixed them together.

15,827. (*Sir John Coode.*) Mr. Lumley Smith wants to know what is the strongest?—Will you kindly turn to page 7 of the second volume; there I give you each sample separately, the first being collected at 4 o'clock a.m.

15,828. (*Mr. Lumley Smith.*) But here you do not give us the albuminoid ammonia?—It was not necessary in that case. It would involve such an amount of work, and the average would be the same thing.

15,829. The fact is, you have not given us the albuminoid ammonia for any single sample?—It would have been too much trouble. There were 24 samples taken upon a single day, and it would have been impossible to have done the work.

15,830. (*Chairman.*) In fact, you have not done that?—I have not; the table shows that.

15,831. (*Mr. Lumley Smith.*) There are five chemists attached to the Metropolitan Board of Works, are there not?—Yes, but these were not done by the five chemists.

15,832. You have drawn my attention to page 7 of your tables; that does give us the result of some analyses of single samples, that is to say, it gives us the chlorine and it gives us the suspended matter?—Yes.

15,833. Those were all taken upon the 29th and 30th of April, were they not?—Yes, they were.

15,834. And there is one upon the 12th of May?—There is a series given on the next page, taken on May 12th and May 13th.

15,835. Are not those dry-weather months?—You may call them dry-weather months; but there was a considerable quantity of rain fell, as I show upon page 7, "Series of Samples collected upon the Southern Outfall," and the rainfall at Greenwich was ·22; at Spring Gardens it was ·34; on May 12th at Greenwich it was ·33, and at Spring Gardens it was ·430; so that those were wet-weather samples and not dry-weather samples.

15,836. Do you represent 27·29 as the ordinary average of suspended matter; is not that the dry-weather average of suspended matter?—No; if you look through the column, you will find that a good deal of rain-water fell, and then, including the dry with the wet ones, you get a fair average.

15,837. What is the highest quantity of suspended matter that you have here; you have one of 27, one of 32, and one of 44. One of 52 seems to be the highest, does it not?—On page 6 of this table there is as much as 76·9 grains per gallon.

15,838. But I want the single samples. Why are you so shy in adopting my suggestion that 27 is the dry-weather quantity?—I deal with the facts; the samples are taken in wet and dry weather, and the actual observation of the analyses gives me 27·29.

15,839. But it does get up, in fact, to 76?—Will you also kindly point out that it does go down to something like 10.

15,840. It must go down if you are to get your average?—On the 29th of March, No. 116, at the northern outfall it is 10·5.

15,841. What is the highest you have ever found?—I think the highest that was ever found was a sample put in by Mr. Keates in the arbitration case, when it came to something under 100, and that was immediately after a heavy storm of thunder, lightning, hail, and rain passed over the metropolis.

15,842. Other people have found 146 grains, have they not?—I have no doubt that under exceptional circumstances you may find even more.

15,843. Heavy rain, as a matter of fact, will give you a very large quantity of suspended matter?—No doubt you will at a particular time find a very large quantity, but after the first rush, if you take a fair average of the samples for the day, not an isolated sample for an hour, you will then get a fair average quantity.

15,844. But it increases for some hours, does it not?—It will increase it for a time. I dare say, when that sample containing 76 grains per gallon was collected, if we had waited till the worst came and then taken the highest figure we could get for the moment, we might have made something more of it.

15,845. The result is, is it not, that in the tables you have given us there are none of an exceptionally high number?—Yes, the 76 one is an exceptionally high one; that is the average for 12 hours; if we had taken one sample upon every hour during 24 hours that occasion, we should have shown some very interesting figures.

15,846. Now, as to your diagram. I do not understand the analyses that were made in 1878?—I thought I had explained them already.

15,847. Why were any samples taken in 1878?—It is known to the Commission, I think, that in 1877 a report was made to the Thames Conservators by Captain Calver as to the condition of the river Thames, and in reply to that Mr. Keates, then consulting chemist to the Metropolitan Board of Works, was ordered to carry out a series of investigations as to the state of the Thames, and in that way a number of samples of Thames water were taken and analysed. Those examinations were made by myself, at least some of them were, and those that were made by myself I have made use of for this present inquiry.

15,848. You will hardly call those 1878 ones that are put into your table No. 1 a "large number of observations," because they are very few; have you picked them out, or were there others?—Those are all that were actually made by myself; there were others taken by other people.

15,849. Are those all that you analysed?—Those are all that I analysed. In 1878 there were 22 samples altogether.

15,850. They are spread over a good many months, are they not?—Yes, throughout the year, and in different places.

15,851. I do not find at any place more than two samples?—We cannot analyse the whole of the river; we have done a good deal of it.

15,852. However, that is the reason you say?—And later on after that, towards the end of the year, after the "Princess Alice" accident, when the complaints were made, further samples were taken.

15,853. The "Princess Alice" went down in the beginning of September?—Yes.

15,854. Will you point me out, with the exception of the two that I see in March, any that were taken in the spring of the year. Out of the whole of your pages 1 and 2, I only find two that were taken in March, one at the northern outfall on March the 11th, and the other at Crossness.

15,855. (*Mr. Michael.*) There were three taken at Crossness?—Other samples were examined.

15,856. (*Mr. Lumley Smith.*) But they are not here?—Because I did not examine them.

15,857. And you do not show the state of the tide in any way on page 1?—Yes, I do in numbers 5, 6, 7, and 8. No. 1 was 5½ hours after high water at London Bridge, and the Victoria Docks 6½ hours after high water; it was an omission not to put that in.

15,858. At Woolwich you do not give us the state of the tide?—No, that was an omission.

15,859. Now we will take Table No. 2. Why have you taken Woolwich as your place at which to make all your observations?—Because at that time there were a very great number of complaints, that is to say, so far as we heard, the major part of the complaints came from Woolwich, and that was considered at the time a very good starting point from which to examine the river, and there the samples were taken.

*Mr. W. J. Dibdin.*

19 June 1883.

15,860. What is the deduction you draw from page 3 at Woolwich, where you give a number of double observations at high water and after high water?—If you turn to Diagram 5 at page 16——

15,861. What deduction do you draw from that?—The deduction which I draw in the first instance is that the contamination of the river at that point is immaterial; it is so small that it really does not come into the question at all as affecting the river from the point of its giving forth emanations which are noxious to people who are travelling upon it or living near it; that the water, according to the state of the tide and the rainfall and other circumstances, varies; that it is not the same thing, but that there is a tolerable mean, and that the variations are very slight.

15,862. You have taken it at high water and an hour after high water; do you draw any deduction from that system of bracketing, as I may call it, the hour of high water with the hour after high water?—Yes, I do.

15,863. What is your deduction from that?—I say that, if we take the high water, which is the water from below the outfalls, and which must receive the sewage from the outfalls, and, as we are told, ought to be the horrid polluting stuff it is said to be, that that ought to be much the worst; but if we look at the figures throughout, we find it is not so; we find that the high water samples which should contain the sewage are on 13 days out of 20 best instead of worst; they contain the least pollution.

15,864. If you turn to your table at page 3, you will find that in No. 28 at high water there is more albuminoid ammonia than there is an hour after, there you get for the high water ·0220, and for an hour after high water you get ·0210, so that there is more albuminoid ammonia at high water?—If you will look at the diagram, you will find it is so shown.

15,865. The following day it is just the reverse, so that there is no law apparent; these lines cross each other?—I simply pointed out the fact that upon 13 days out of 20 the high water was the best, but the general conclusion to be drawn from it is simply that the water was not in the horrid condition in which it is said to be.

15,866. If you confine yourself to that, that is one thing; but I thought you drew a comparison between the state of the water at high water and an hour afterwards?—And so I do draw a comparison between water at high water and water an hour after high water.

15,867. Now your diagram No. 1 is to illustrate your sharp line of demarcation, and I understand you to say with regard to your two blue lines that one was taken at one end of the boat and one at the other, to show that there is so very much more organic matter in the sewage than there is just upon the other side of the line?—It is the red lines which were taken from the boat.

15,868. What do the blue lines indicate?—I took one 200 feet from the northern outfall and the other at 600 feet.

15,869. So far as the blue line is concerned, it teaches nothing, does it?—It is not so sharp.

15,870. But one is taken at 200 feet from the northern outfall and the other is taken at 600 feet?—Yes, that is clear.

15,871. If you look at diagram No. 1 with regard to your red lines, does one represent the observations taken at one end of the boat and the other the observations taken at the other end of the boat?—Yes.

15,872. I suppose the sewage flow is at times a good deal more than one boat's length across?—Yes, but this is right away from the outfall; this does not represent the sewage stream at all.

15,873. I just want to understand the wording of your statement at page 11; what do you mean by the "shore side of line of junction"?—As the sewage comes out from the outfall it meets with the river water, and there is a very distinct line of junction with the river water where they meet.

15,874. There would be two lines, would there not?—It is not so noticeable upon the shore side; it is where the body of the river water meets with the sewage.

15,875. You have taken the line, have you, out towards mid-stream?—Yes, but it is very close in towards the shore as compared with the bulk of the river water.

15,876. Now I want you to look at diagram No. 2 on page 15; you give there the amount of albuminoid ammonia near the surface and the amount three feet from the bottom?—Yes, on August 11th.

15,877. Does not that show that there is more albuminoid ammonia at the surface than there is at the bottom?—Immediately near the outfall; at the outfall it is precisely the same; but then, if we go to Barking Creek, there is rather more at the surface there, and also at Lawes' Chemical Works; but as we follow that line down, we find, when we get to the two powder magazines, about 1,000 yards or a little more than 1,000 yards, it shows that the mixture is practically complete and remains so.

15,878. Is it not the fact that the polluted stuff is more apt to remain at the top than to go to the bottom?—At the outfall it is so, but the distance is really nothing upon the river; upon the diagram it seems a good deal, but it is really nothing, because we have taken only from the outfall to Crossness Point, which is a very short distance indeed.

15,879. Now with regard to the next diagram, No. 4; you made a remark upon that diagram, and also with regard to the next diagram, No. 5, that the more chlorine there is, the less albuminoid ammonia you get; is not that so?—At Woolwich that is so, but at Erith we are below the outfalls and in a different condition of things.

15,880. Is it not so everywhere that the water is better at high water all along the river?—No.

15,881. Professor Heaton gave us that difference. I ask you, do not you agree that at high water you find noticeably less ammonia all along this part?—Not at all.

15,882. But let us look at your diagrams; your diagrams, as far as they go, all show that that is the case?—Which of them, because these diagrams show totally different things?

15,883. Do not these diagrams all show that, as the chlorine mounts, the albuminoid ammonia falls?—It is so with regard to the Woolwich diagram.

15,884. Is it not so with regard to all of them?—No, it is not so with regard to Erith.

15,885. Will you point out where it is not so?—I am referring to low water at Erith, diagram No. 4; there on the 31st August the chlorine at Erith is low and the albuminoid ammonia is high——

15,886. That proves the same thing, that they go in opposite directions?—But next day we find it is different.

(*Mr. Michael.*) If you look at page 5, and take the contrast between high and low water, there is the answer to your question. The albuminoid ammonia upon that page at low water is ·0192 and the chlorine 1·27. When you come to high water the albuminoid ammonia is increased to ·0278 and the chlorine is 10 times as much, namely, 12·04. There is an increase, therefore, of albuminoid ammonia with 10 times as much chlorine.

(*Mr. Lumley Smith.*) But you have got up to Blackwall.

(*Witness.*) But you asked me if it was not so throughout the whole length of the river.

(*Mr. Michael.*) The albuminoid ammonia at Erith at low water is ·02 and the chlorine 13·2, and at high water the chlorine is nearly 10 times as much.

15,887. (*Mr. Lumley Smith.*) And that water at Blackwall pier is water which has come past the outfalls?—But when we are at low water at Woolwich we have less chlorine than we have at London

Bridge, and we have the water at Woolwich at dead low water which was at high water further up the river.

15,888. Do not you find that, as the sewage water comes in, the albuminoid ammonia stands in its relative proportions?—The diagrams do not show that; they show the water coming up (*referring to the Woolwich diagram*) which had received the sewage, and we find it better than the water which has gone up further and come down. At the same time, I do not wish to draw too much inference from that view. What I say is that, if we take the very worst time of the water in the river, as shown by the figures, yet the condition of the water is not such as that it can become offensive.

15,889. Passing to diagram No. 4, I notice you have observations of two consecutive days; the dotted lines represent the chlorine upon those two days, and those are pretty much constant; you get about the same sea water at this time of the tide?—Yes.

15,890. But I find that the amount of albuminoid ammonia is exceedingly different on those two consecutive days?—Yes.

15,891. So that on two consecutive days you find with the same amount of sea water a very different amount of pollution, as evidenced by the albuminoid ammonia?—Yes.

15,892. Does not that show that albuminoid ammonia is a process which does not give you any fair results?—No, on the contrary, I think it is a point which brings out the character of the albuminoid ammonia test very satisfactorily indeed.

15,893. Why so?—Because upon the first day those samples were taken, as I think I mentioned in my evidence-in-chief, it was an exceptionally high tide, and at low water we had the water charged with the sewage from the outfalls, it had just come past the outfalls and had received sewage, and was to a certain extent rendered worse than it was before. That is the effect of that day's tide. Then, the night's tide and the next day's tide coming into play, there being an exceptionally high tide, there is a very considerable scour of the river; the quantity of impure water which was in the river has been carried out and replaced by the fresh water from the sea; and we find, in consequence of that, that upon the second day samples taken at the same place give us a less impurity.

15,894. This great bulk of sea water washes out the river, is that so?—Undoubtedly it is so, I think the diagram shows that the albuminoid ammonia agrees with the common sense of the thing.

15,895. You have no observations corresponding to those at Woolwich in diagram No. 5, lower down the river, have you?—No.

15,896. According to the lines there the chlorine is always less an hour after high water, have you any corresponding observations to those lower down the river?—No, I think I have done all that was possible.

15,897. Before we pass from No. 5, the chlorine as a rule increases with the spring tides, does it not?—Yes, it should be so.

15,898. And that would be at the full moon?—Yes, or just afterwards.

15,899. When you have your full moon on the 20th of August, do you not find an extraordinary depression of chlorine, and can you give any explanation of that?—The 16th, the 19th, and the 23rd, I have.

15,900. That would be the period of spring tides, would it not?—Yes, going from neaps to springs.

15,901. Now I want to point out to you that diagram No. 7 shows the condition of the water above Barking and below Barking, it is for the purpose of comparing the state of things upon half flood and half ebb; now you see at Barking Creek, or immediately below there, the blue lines and the red lines cross each other, they are equal, if you notice?—Yes.

15,902. So the half ebb and the half flood are equally good; that is so, is it not?—Yes, at that point.

15,903. Now, when you come above the outfall, do not you find the half flood is worse than the half ebb above Barking?—When we come to Woolwich it is worse.

15,904. There is more albuminoid ammonia in the half flood above Barking than there is in the half ebb?—Yes.

15,905. Does not that show that the water which has come past the outfall is worse than that which by the half ebb is coming down from the upper river?—But may I point out to what extent that is so. It shows, looking at the scale, taking the half ebb at the surface and the half flood at the surface, the difference between ·023 and ·025, being a difference of ·0020. In London drinking water we get ·005, so that the difference is not so much as we get in ordinary drinking water, in fact, the difference is so microscopic that it is of no moment.

15,906. Now if you will look at No. 7 at the bottom, you will see that the bottom is the worst throughout?—That is very natural indeed.

15,907. Now if you look at No. 8 at the bottom, the half flood is the best throughout?—Looking at these figures, they are almost identically the same, the difference there is not more than the error due to manipulation.

15,908. Does not it all go to show that the results of albuminoid ammonia are not to be relied upon?—It goes to show that the composition of the water there is constant practically, and also it shows that the process is a very reliable one indeed, because, whatever process you use, there will always be the error of manipulation, and these differences are really little more than what that comes to.

15,909. These samples which you have taken, upon which your volume 1 is based, are all single samples, are they not, they are not taken across the stream up and down?—No. these are single samples except with regard to the Erith ones, which are samples taken across the river at three different points, and at the surface and half depth, so that each sample is really a mixture of six. We wanted to get a fair picture of the condition of that water, so we took three samples at the surface and three at half way down, and mixed the six together.

15,910. You have given us at pages 9 and 10 of your first volume the quantity of albuminoid ammonia at different places. I will take Woolwich, and I will take Greenhithe. You there show that in a gallon of water at high water you find more of the albuminoid ammonia at Woolwich than you do at Greenhithe, you find ·032 at Woolwich?—They are half flood and half ebb; taking the mean, they are ·030.

15,911. What I put to you is this, do you suggest that that is due to the improvement of the water from the albuminoid ammonia having disappeared, or to dilution from its being mixed with a larger quantity of water?—At Woolwich as against Erith?

15,912. No, at Woolwich as against Greenhithe. Have you worked it out at all by the cross sections to see how much albuminoid ammonia there is in the whole section of the river at Woolwich and Greenhithe, so as to compare the two?—No, not further than what is stated in the table. At Woolwich there is only five to six times what we find in ordinary drinking water, and twice as much as we get at Teddington, and at Greenhithe there is only four times what we get it in drinking water and less than twice as much as we get at Teddington; the difference is practically nothing.

15,913. You have not given me the amount of albuminoid ammonia in the sea water?—No, I have not done that.

15,914. Are you able to tell me whether the mixture of sewage and sea water does not turn the sulphates into sulphides?—That is a very important question, and it is so. The organic matter and the sulphates react upon one another, and sulphides are formed, and then we have ferruginous clay which is suspended in the river water acting as a purifying agent by absorbing

*Mr. W. J. Dibdin.*

19 June 1883.

the sulphuretted hydrogen so formed, and we get in that way the black colour of the mud.

15,915. It does cause the sulphuretted hydrogen to be given off, does it not?—It does not cause it to be given off, but to be immediately seized by the clay which is suspended in the water.

Cross-examined by Mr. Beaumont Morice.

15,916. I wish to ask you a question about what you said with regard to the drains of Erith; how often have you been down, taking samples from these drains?—I have not actually, with my own hands, taken samples from these drains, but I have examined these drains as recently as last Saturday, and there I found solid fæces, and, as I stated, slaughterhouse refuse, guts, and blood, lying upon the hard; so that I can well understand the complaint that is made.

15,917. Have you made any estimate of the quantity, the volume, coming out of the drains?—I have not. I am not an engineer.

15,918. What time of the tide was it?—It was at low water.

(*Chairman.*) What the witness said was this, "I "cannot tell you the quantity, either absolutely or "relatively to that of the Thames, and if it had been "discharged into the Thames in a reasonable way, it "would not have been of any consequence at all, "but I mentioned it to account for the stinks which "the people complain of; it was emptying upon the "foreshore, with a strong sun upon it."

15,919. (*Mr. Beaumont Morice to the witness.*) Did you remain there at any time?—No, but I saw what I saw, and that would remain there until the tide came and washed it away, if the tide was sufficiently high to do it; if it was not, it would remain there till the tide was sufficiently high to do it; it was not upon the mud, but upon the hard.

15,920. How far was it from the causeway?—There is a hard wall built along, coming to the foreshore just above the mud.

15,921. Did you land at all?—Yes, we landed and walked up the causeway, and went along the foreshore until we came to the drains.

(*Chairman.*) Are you going to make out that Mr. Dibdin did not smell it?

(*Mr. Beaumont Morice.*) I only wanted to know whether he was there any length of time.

(*Chairman.*) He was there long enough to smell it

Re-examined by Mr. Bidder.

15,922. I have only two questions to ask you in re-examination; is there any method of analysis known to chemists that gives you certain absolute indications as to the source of the organic matter present in the deposit?—I know of none whatever; they are all relative.

15,923. Your albuminoid ammonia, which you took for comparison, with sewage, yields, as I understand, a certain standard quantity?—That is so.

15,924. And you may get albuminoid ammonia where there is no sewage?—You may do so, but not on the Thames to any appreciable extent.

Examined by the Commission.

15,925. (*Dr. Stevenson.*) With regard to the ferruginous clay and the sulphuretted hydrogen, when that clay carries down the sulphuretted hydrogen, do you think the sulphuretted hydrogen ever comes up again, if I may use the expression, is it ever given off again?—I think not; rather I think there is oxidation going on, and the same thing happens in the water as it would in the atmosphere; the iron is converted into oxide of iron and the sulphur is set free.

15,926. You were asked about the urea in the water not yielding you albuminoid ammonia; would you not get the ammonia in one form or another from the urine in the water?—You would get it as free ammonia, the greater part of it. I think, if the analysis were carried on according to Wanklyn's instructions, you would get very little urea left; it would be all destroyed in the preliminary boiling.

15,927. Do you ever get any peaty matter in the Thames?—There is a large amount of vegetable matter in the Thames, but I should not consider the Thames would be called a peaty river.

15,928. If there were any albuminoid ammonia derivable from peat in the water, you would find it at Teddington, would you not?—We know that there is a certain amount of albuminoid ammonia derived from peat at Teddington, but we know the Thames is not a peaty river, and we know that there is a considerable quantity of sewage discharge into the river above Teddington.

15,929. (*Chairman.*) When sewage is smelt either by me or anybody else with an unscientific nose, what is it that we smell? Is it any gas, because one knows there may be a smell without any gas, such as the smell of a rose or of musk, without anything being given off; is that the case with sewage, as far as you know?—I believe it is. I cannot say that I know of anything that is given off.

15,930. You smell it, as it were, in the same way as you would smell a rose?—Yes, as your Lordship expresses it.

15,931. What causes it to cease to have that smell; can you tell me?—When the matters which give rise to that odour are destroyed, either by oxidation or other cause.

15,932. We know that practically nothing is destroyed, but that it is converted into other things?—It is destroyed as sewage.

15,933. But the materials remain?—The carbon of which a part of the sewage consists would be converted into carbonic acid gas.

15,934. What becomes of that?—That may be dissolved in the river water, and probably unite with lime or other substances to form carbonate of lime or chalk.

15,935. And some of it may go into the atmosphere?—No doubt it would.

15,936. If the water was overcharged?—Yes, as a bottle of soda-water would discharge the surplus of carbonic acid gas which it contains.

15,937. What would become of the ammonia?—It would in part be lost by evaporation, and in part be converted into nitric acid and combine with the alkaline salts which are found in the river to form nitrates.

15,938. We have heard that there is a considerable amount of solid in a man's fæces and urine. I think it was stated to be 3½ ounces a day; what becomes of that matter?—It is first of all broken up, and enters into solution with water, and then the ultimate fibres become further decomposed, and the nitrogen converted into ammonia, and so on, and the carbon into carbonic acid, the mineral matter remaining as mineral matter; that would remain in solution as carbonates, sulphates, and so on.

15,939. What would become of it?—That would enter into solution with the river water, and go out to sea.

15,940. This mineral matter would?—The soluble mineral matter would.

15,941. Or any matters which are not soluble?—Undoubtedly they would in ordinary fæces.

15,942. What would become of them?—Those would be held in suspension, and carried away with the ordinary suspended matter of the river.

15,943. They would be heavier than the river, would they not?—No; we find that the specific gravity of sewage suspended matter is little more than half that of the river suspended matter, so that, if the river suspended matter is carried out to sea, it is reasonable to suppose that the sewage suspended matter will be, if it is not oxidised and destroyed before it gets there.

15,944. The sand and gravel, and things of that sort, which are brought down, would be in suspension for some time and would deposit if an opportunity were given them to do it?—Undoubtedly.

15,945. But as to the organic matter, your statement is that it would be resolved into its constituent parts, which would either be gaseous and escape, or which would remain in suspension in the water, but, being lighter than the water, would be carried out to sea?—Undoubtedly, if they were not oxidised and further resolved into their elements by the purifying power of the river.

15,946. When this sewage first comes out you smell it?—Yes, at the outfall.

15,947. But how far do you say you smell it so as to describe it as being appreciable?—It depends entirely upon the state of the atmosphere and the wind, and so on. On an ordinary calm day, when there is very little wind, and when you see the smoke from the factories and steamers rising up into the atmosphere in a steady cloud, you may smell it when you are in a small boat for 600 or 700 yards or less, as the case may be; but if it is a rather rough, cold, windy day, and the water chopped about a bit, the odour is gone in an astonishingly short time.

15,948. Do you smell it at all on its return?—No, it goes down the river, spreads, and mixes with the body of the river water, and is for all time lost.

15,949. But it has been admitted very candidly that it must come back?—To a certain extent a little must come back.

15,950. We have heard about the wells of the fishing boats; it seems very much to be admitted to be true, that somewhere about Gravesend they can no longer keep their fish there; what do you attribute that to; to the sewage?—I attribute that not to the sewage directly, but indirectly, the sewage having absorbed the oxygen which is dissolved in the water and so rendering the water in a condition which is not fit for sustaining the life of the fish. They require oxygen in their breathing as we do, and if the oxygen is taken out of the water, then they will die.

15,951. They will suffocate, will they not?—Yes, they will suffocate.

15,952. (*Sir John Coode.*) Indirectly it is due to the sewage?—Indirectly it is due to the sewage.

15,953. By the absorption of the oxygen which is necessary for the keeping of the fish alive?—That is so.

15,954. Have you determined by actual experiment that the specific gravity of the sewage matter in suspension is, for all practical purposes, half that of the river solid matter in suspension?—Yes, and for all practical purposes it is half. A good many estimations were put forward by Sir Frederick Abel in the last inquiry which I have no doubt he will bring forward again before you, in which that was brought out very clearly.

15,955. (*Chairman.*) Although the water has lost its due proportion of oxygen, it does not become fœtid or objectionable, does it?—Indeed, no; because there is a very rapid action and re-absorption of oxygen; as it is deprived of its oxygen, it goes on to absorb oxygen from the atmosphere.

15,956. We know that at Gravesend it is salt water and in no case potable?—It is not.

15,957. Is water deprived of oxygen of itself potable?—Yes; it could be drunk as a matter of fact, without injury.

15,958. Supposing the sewage had run through fresh water instead of salt, do you say it would have become potable by that time, though it were not fit to sustain the life of fish from the want of oxygen?—I should not like to say that. The very fact of its absorbing oxygen shows that the water had contained matter which ought not to be present in drinking water.

15,959. You say that the sewage and the oxygen in the water unite; that the water becomes de-oxidised, as it were; it wants more oxygen and it absorbs it from the atmosphere?—Yes.

15,960. You also said, as I understood, that the water from which the oxygen had been abstracted could be still said to be potable and not injurious to health?—Yes, if it contained nothing injurious to health.

15,961. I thought you had made out that it contained nothing injurious to health because that would have been oxydised?—If the oxygenation were completed.

15,962. You think there is still some unoxidised sewage down at Gravesend?—Yes, a small, but a certain quantity.

15,963. (*Professor Williamson.*) I should like to ask you one question upon a matter of some importance, which I really do not clearly understand; and I think the Commission generally will be glad to have more clearly the bearings of your results which you have brought so fully before us, and that is with regard to the interpretation of the albuminoid nitrogen. You will see my difficulty better if I enter rather fully into my present state of ignorance as to your views upon this subject. You determine the albuminoid ammonia by Wanklyn's process under different conditions, at different places; and, as I understand, you use that as a measure of the noxious constituents in the water. Now, sewage consists not only of dissolved organic materials, for it is the dissolved organic matter which you determined, and not the suspended matter, but it consists also of fæces and matters of an objectionable kind which are present with it. Now, I think it would be of some importance if you were to state definitely the grounds which you have, if you have them, and if I rightly understood you, for expressing the opinion that the dissolved nitrogenised organic matter of which you get a comparative measure by this process, such as it is, is a measure of the noxious quality of the water, and that the suspended matter, not dissolved, but merely mixed up in it, is not material to it; because, of course, we know that there is solid matter suspended in it, more or less, and one is inclined, *primâ facie*, to look to that quite as much as to the dissolved organic nitrogenised matter. I presume the urea is probably decomposed before you analyse it, and that the chief sulphur compounds and the fœtid things are in the solid materials which go into the sewage, I presume. I do not know whether I have made clear the difficulty which presents itself to my mind. I have no doubt you have some definite grounds for believing that the quantity of nitrogenised organic matter which is dissolved is a measure of the noxious character of the sewage mixture, and that the solid matter does not need to be included in the calculation?—I think I have stated that I have dealt in the albuminoid ammonia estimations with that quantity of impurity which is in solution both in the sewage and in the river water, and that quantity is the most important, as I take it. The average amount of suspended matter in the sewage, as I have shown, is equal to 27 grains per gallon; we discharge the sewage into about something over 200 times its bulk of river water, and the mixture, as we see, is complete.

15,964. I thought you said the solid organic particles were lighter and floated, in the main?—I think I may say I have not dealt with the suspended matter, as you will have very full evidence given you upon that point. I have dealt only with the matter in solution as being more in my province in this case. I have had my time occupied more with that. The question of the disappearance of the suspended matter of the sewage has been dealt with by other hands, and you will have very full evidence upon that point; if

*Mr. J. Dibdin.*

19 June 1883.

you will allow me, I would rather leave that question to the Commission.

15,965. So you are not prepared to say that the dissolved nitrogenous organic matter is a measure of the objectionable character of the water?— That is one point in the case and I have dealt with it in relation to the dissolved matter. I quite admit that the suspended matter is another question, and must be dealt with separately; that has been entered into by another witness who will be called before you.

The witness withdrew.

Dr. AUGUST DUPRÉ, Ph.D., F.R.S., called in; examined by Mr. BIDDER.

*Dr. A. Dupré, Ph.D., F.R.S.*

15,966. You are a Fellow of the Royal Society and lecturer on chemistry at the Westminster Hospital?—I am.

15,967. You have known the Thames for a great number of years, I believe?—I have for 27 or 28 years.

15,968. I think you have had opportunities of generally observing the banks for upwards of 20 years?—Yes, the banks all down the river. I used to go down very often shooting at Canvey Island, near Southend, and at that time we found enormous quantities of mud there; it was necessary to have high boots up to the thigh to walk at all in many places.

15,969. What was the character of the mud?—The mud was very sticky, so that, even with the high boots, you had generally to take hold of the boot if you got into a bad place, or else it would have been dragged off. The mud was generally of a brown colour at the top, and very frequently black below.

15,970. I think, as far back as 1857 or 1858, you were engaged in conjunction with Dr. Odling in making analyses of Thames water?—We made a great many.

15,971. What parts of the river were those taken at?—They were chiefly taken at Greenwich, but we took them also up at Lambeth, and I think a little higher.

15,972. Those analyses, I think, were not conducted with the same completeness which the progress of modern chemistry has suggested?—No, they are not of a character that they can be compared with the present analyses.

15,973. Still they gave you certain indications of the condition of the water?—They did, and they brought out Mr. Baldwin Latham's mixing action very clearly; we took several samples at various parts across the river, and down to various depths, and we found quite clearly that as the tide runs up the salt water goes up the centre and in the deeper water, and leaves the sides comparatively free. The lower samples up to London Bridge frequently were distinctly more salt than the surface samples, showing that the salt water runs up below, whereas when the tide goes down the condition of things is reversed, the fresh river water then goes down the centre, and leaves the sides comparatively salt, so that there is a very considerable mixing action going on.

15,974. Does a comparison of those with the samples which you have recently analysed enable you to make any statement as to the relative purity of the river above Greenwich at the two periods?—Scarcely with regard to the water; the analyses are too different to be of any use for the purposes of comparison. I only know from being frequently upon the river, from personal observation, that there is no comparison in purity now to what it was 25 years ago.

15,975. You mean that the river is better above Greenwich?—It is infinitely better.

(*Chairman to Mr. Bidder.*) You may take that as admitted.

15,976. (*Mr. Bidder.*) Then with reference to the amount of suspended matter, how does that compare?—That was done in the same manner as it is now, and can be perfectly compared with recent results. There are some rather interesting results with regard to that; first we find that in the year 1857 the average of suspended matter at Greenwich between June and September at high water was 2·43 grains per gallon, and at low water 4·57 grains per gallon, but perhaps the more interesting point is that during the same months in 1882 we find 4·05 at high water and 3·93 at low water, but the mean comes to very nearly the same.

15,977. As regards the percentage of that which was of a volatile character, indicating organic origin, what was that?—That was determined in Greenwich in 1857 at high water as being 35·39 per cent., and at low water 26·45; that is to say, it was considerably more at high water than at low water, and the same thing happens to be the case now, only the difference is not quite so marked. In 1882 at high water it was 24·9, and at low water it was 20·2, in both cases it was more pure at low water.

15,978. There is the same excess of percentage at high water over the low, but the percentage of volatile matter is absolutely smaller in 1882 than it was in 1857?—It is very decidedly smaller.

15,979. Is one entitled to draw from that fact the deduction that the suspended matter of the river contains a smaller percentage of organic matter now than it did?—I think so.

(*Chairman.*) I do not see how this is relevant; the question is not whether you have made Greenwich water better than it was, but whether it is still not as good as it ought to be.

(*Mr. Bidder.*) I suppose everybody would admit that it is not so good as perfect water.

(*Witness.*) There is one point I should like to bring out, namely, that in 1857, when all the sewage went in above Greenwich, nevertheless the suspended matter at high water was worse than at low water, and the same is the case now, though we might come to the conclusion that it was worse now, because the suspended matter from Barking comes up the river.

15,980. (*Mr. Bidder.*) You mean that the fact that at high water you have a higher percentage of volatile matter than at low at Greenwich does not indicate the outfalls below as being the source of that volatile matter, because the same fact, obtained at a time when the sewage was put in above?—Yes, that is so. If we had only our recent results to go upon, we might come to the conclusion that the sewage discharged at Barking carried the foul matter up the river, but we cannot come to that conclusion, because 25 years ago the same condition obtained when the circumstances were reversed.

15,981. (*Sir John Coode.*) Did you make many experiments 25 years ago?—Yes, I did.

15,982. Extending over what time?—Extending over a year and a half.

15,983. When you go to Woolwich, what is the condition of things in that particular aspect at Woolwich as regards the percentage of volatile matter in the suspended matter at high water and low?—At Greenwich in 1857 it was 35·39 at high water and 26·45 at low water, that is to say, the percentage of volatile matter in the suspended matter.

15,984. (*Professor Williamson.*) Do you mean volatile, taken in the common sense?—No, that which would pass off by ignition.

15,985. Not volatile *per se*, but volatile when you burn it?—Yes, as distinguished from mineral matter. I do not wish to call it "organic matter," because it is not all organic matter.

15,986. (*Sir John Coode.*) I wish also to know what were the relative proportions of the suspended matter?—I have given them; they were 2·43 at high water at Greenwich and 4·57 at low water.

15,987. (*Mr. Lumley Smith.*) Then it was less at high water?—It was less at high water, but the

quality was much worse. Now at Woolwich at the present day it is just the reverse. The amount of matter that can be burnt off from the suspended matter in the river at Woolwich is less at high water than at low water.

15,988. (*Mr. Bidder.*) That is to say that, taking that as an indication of organic origin, the percentage of organic matter in the suspended matter, when the tide is coming up from the direction of the outfalls, is less at Woolwich than when it comes down from the upper part of the river?—Yes.

15,989. (*Professor Williamson.*) How is the proportion of solid matter per gallon of water. You say per unit of solid matter it is less, but per gallon is it less?—I have given the figures; in 1857 at high water it was 2·43 grains per gallon of suspended matter, in 1882 at high water 4·05, being rather more. At low water in 1857 it was 4·57 grains per gallon, and in 1882 3·93, which is less.

15,990. I think the Woolwich samples showed great uniformity; last year very few samples had any great excess above the mean?—There were only two samples out of some 200 samples that were above the mean as found 27 years ago at Greenwich. There was one at Woolwich at low water which was 37·2 per cent. as against 35·0, and one taken at high water at Greenwich which gives 40·3 per cent., but altogether the suspended matter in the river in that part is decidedly better in quality than it was in the river 25 years ago.

15,991. (*Mr. Bidder.*) Now, passing from the suspended matter, I will come to the samples you have taken in the last two or three years, but I should just like to ask you first with reference to the different methods of analysis as applicable to the discussion of such a question as this now before the Commission?—There are three methods now usually adopted by chemists for the purpose of estimating the relative quantity of organic impurity in water. There is no method known which gives the absolute quantity, but we can draw general conclusions. The oldest process now is that which is known as the permanganate process. The principle of this consists in estimating the amount of oxygen which the water takes from the permanganate. Dr. Tidy stated distinctly that the process was not applicable to the Thames where there was sea water, and that, therefore, he had abandoned it. But in my judgment, if it is properly worked, it is just as applicable in the case of sea water as it is in the case of fresh water. If you make the analysis in an open vessel, as Dr. Tidy according to his own description does, the permanganate process is not applicable, but if you do it in a close vessel, it gives equally good results in salt water as it does in fresh water, and we have adopted that process all through the river.

15,992. By that process do you ascertain how much oxygen is required to supply the normal quantity to the water?—No, that is not so. The more organic matter present in the water, the more oxygen it will absorb, and the less the organic matter, the less oxygen it will absorb.

15,993. Now, without going into detail, what is the second method of analysis?—The second method of analysis is what is known as the albuminoid ammonia, or Wanklyn's process, which estimates the organic matter by the amount of ammonia evolved when boiled with an alkaline solution of permanganate. That process, like the oxygen process, is only relative and not absolute, but inasmuch as in the River Thames the impurity below Teddington is everywhere sensibly the same, you get good comparative results.

15,994. That is the same process as Mr. Dibdin has been speaking of, the albuminoid ammonia process?—Yes; you get no absolute results from it, but you get comparative results.

15,995. Now what is the third method of analysis?—Professor Frankland and Armstrong's process to estimate the organic carbon and the organic nitrogen, but this, like the other process, gives only relative results, and in the case of the River Thames it is not applicable, because sea water gives very much organic carbon and very much organic nitrogen, so that the organic matter in sea water is fouler than the sewage itself, if we take that analysis as our guide; whereas both the oxygen and the albuminoid ammonia process show the sea water to be pure.

15,996. You mean that, if you take by that process the organic carbon and the organic nitrogen as a guide to the impurity, it leads you to the result that any sea water is a very impure water?—Yes.

15,997. Because of the carbon and nitrogen in the sea water?—Yes, and the relation between the two is such as to lead you to the conclusion that it is worse than sewage. Professor Frankland himself abandoned the process, as not leading to any conclusion, therefore the processes we have adopted in all our analyses is the amount of oxygen absorbed from permanganate, and the amount of albuminoid ammonia evolved.

15,998. You believe these to be the more reliable processes?—I believe they are in this case.

15,999. You have made a large number of analyses of the water taken from all parts of the river, and you have also made an analysis, for the purpose of comparison, of ordinary London sewage, have you not?—I have.

16,000. In the first place, would you give, for the purpose of comparison, the result of the analysis of true London sewage?—The average during the year 1882 of true London sewage is that it contains 12 grains of chlorine per gallon, it yields 0·44 of albuminoid ammonia, it absorbs 2·8 grains of oxygen from permanganate, and holds about 25 grains of matter in suspension.

16,001. Analysing that suspended matter, what percentage is volatile, and what percentage is fixed?—64·5 per cent. is volatile, and 35·5 per cent. is mineral; the volatile matter contains 5·75 per cent. of nitrogen.

16,002. You have also gone carefully into the question of the amount of matter per head of population that goes into the sewers?—I have.

16,002*a*. You had better give this figure according to your own results?—Per head of population, taking a mixed population, it comes in the form of fæces to one ounce, and in the form of urine to 1·68 ounces, that is when dried at 212 degrees. Out of this 1·68 ounces, roughly speaking, half is urea, and that urea is all converted into carbonate of ammonia before it reaches the river.

16,003. Before you analysed it was your analysis made of the sewage which contained no urea?—Yes; I am giving the total solid matters which go into the river. Of the remainder, only one fifteenth is organic matter; the rest is mineral, chiefly chloride of sodium, common salt.

16,004. (*Sir John Coode.*) Are we to understand that these samples were taken at the mouth of the sewers, as the sewage fell into the reservoir?—A number of samples were dipped out of the sewers as they came from the reservoir into the river.

16,005. (*Mr. Bidder.*) But your former samples of standard London sewage were taken at an earlier stage?—What I am now giving are general figures taken from a variety of sources, not any sort of analysis.

16,006. Those are the contributions per head of population?—The samples taken at the outfall sewer contained no urea.

16,007. (*Sir John Coode.*) I want to know at what particular point the samples were taken which you say were taken from the sewers?—They were taken either out of the main reservoir, or out of the sewer which is discharging into the river. The total amount of organic matter out of the 1·68 ounces of urine solids which actually goes into the river, and pollutes the river, is only ·056 of an ounce per head. From the 1 ounce of fæces about ·14 of an ounce is also mineral matter, and I estimate that the total amount of organic matter per head of population which actually goes to pollute the river is only ·916 of an ounce per head, which,

*Dr. A. Dupré, Ph.D., F.R.S.*

19 June 1883.

taking 4,000,000 of people, comes to about 100 tons a day, or 36,500 tons a year.

16,008. There was some question of that when Professor Way was here. I do not know whether you greatly differ from him, but what would be the amount of oxygen that you would require to oxydise that?—I should say it is certainly less than 200 tons; we get therefore only 100 tons a day against the "400 tons of filth" which Dr. Tidy calculated as being discharged into the river.

16,009. (*Mr. Bidder*) I think Dr. Tidy afterwards said that there was a mistake about that; that part of that was moist. (*To the witness.*) Now, coming to your analysis upon the condition of the river, I suppose there is generally more or less turbidity all the way from Teddington to Southend?—Yes, always.

16,010. Do you find the amount of suspended matter varies very much even in the same place?—It varies very considerably even in the same place.

16,011. Whether it be up at Teddington or down below?—Yes.

16,012. What do you say from analysis as to the composition of the suspended matter in different parts of the river?—The composition of the suspended matter in different parts of the river is really very much alike, but sometimes the suspended matter is worse at the upper part of the river; actually at Teddington, for example, than it is at Crossness.

16,013. By "worse" do you mean in the sense of having a larger percentage of volatile or combustible matter?—Yes, and even in regard to nitrogen sometimes.

16,014. You have before you a table which shows the figures from places all the way down?—Yes, upon January 15th, 1878, samples were taken at many stations down the river every hour during the 24 hours, at the top, and bottom, so that at each station no less than 37 samples were taken, and they were all analysed.

16,015. You show a certain increase in grains of suspended matter per galllon, I think, as you go down the river, but with, however, considerable irregularity and fluctuation?—Yes; no definite line can be drawn, that is to say, no curve can be drawn that gives it, but the striking fact brought out in this early analysis is that the percentage of volatile matter, or matter which can be driven off, is actually higher in the upper portions of the river than it is in the lower portions.

16,016. (*Chairman.*) Is the insoluble and unvolatile matter in the sewage, that is to say, the mineral matter, as I suppose you would call it, larger in proportion to the bulk of the sewage than it is in the ordinary turbidity of the water?—No, not in actual sewage. In the sewage the mineral matter is very much less, in sewage the mineral matter is only 33 per cent., that is to say, roughly, one third.

16,017. (*Sir John Coode.*) But that will vary very much, will it not, with the rainfall?—I am speaking of the percentage in the suspended matter, not the actual amount.

16,018. (*Chairman.*) But the question I asked was whether it was less in sewage than the proportion of suspended mineral matter in the ordinary water?—It is much more in the sewage itself.

16,019. There is less water to carry away the suspended matter in the sewage than there is in ordinary river water?—

16,020. (*Mr. Bidder.*) In the sewage you have 25 grains of suspended matter to the gallon?—Yes.

16,021. In ordinary water, how many grains have you?—It varies from one to ten or twelve grains as the average.

16,022. There is not so large a vehicle for the suspended matter in the sewage then as there is in the pure water?—Certainly not.

16,023. You took similar samples, I think, in examining this suspended matter in July last year and January this year; do they show you similar results?—Yes; they show that upon the whole the suspended matter contained less volatile matter than in the earlier years.

(*The witness handed in a bound copy of his analyses. See Appendix* B Z.)

Adjourned to-morrow at half past 12 o'clock.

---

# FORTY-SECOND DAY.

## Wednesday, 20th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

| | |
|---|---|
| SIR JOHN COODE, Mem. Inst. C.E. | FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S. |
| COLONEL C. B. EWART, C.B., R.E. | THOMAS STEVENSON, Esq., M.D. |
| PROFESSOR WILLIAMSON, F.R.S. | JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst.C.E. |

WILLIAM POLE, Esq., F.R.S., *Secretary.*

Dr. AUGUST DUPRÉ called again; further examined by MR. BIDDER.

20 June 1883.

16,024. (*Mr. Bidder.*) My Lord, I have here the tables with regard to which Dr. Dupré gave evidence yesterday, viz. the analyses of samples of suspended matter, and the percentage of volatile or combustible matter in the suspended matter in different parts of the river in 1878 and 1882, and I would be glad that they should be put upon the notes; but I will not occupy the time of the Commission by going through them in detail now. (*The following tables were handed in.*)

SAMPLES OF WATER WERE TAKEN IN MID-STREAM, AT AT EACH PLACE EVERY HOUR DURING ONE DAY ON THE SURFACE, HALF DEPTH AND BOTTOM. EVERY FIGURE IS THEREFORE THE MEAN OF 37 ESTIMATIONS.

| Place. | Grains of suspended matter per gallon. | Percentage of volatile matter in suspended matter. |
|---|---|---|
| Teddington - - | 1·07 | 33·6 |
| Kew Bridge - - | 1·24 | 23·8 |
| Westminster Bridge - | 1·67 | 20·9 |
| London „ - | 2·96 | 31·7 |
| Greenwich - - | 4·24 | 20·2 |
| Crossness - - | 7·54 | 17·1 |
| Erith - - | 3·27 | 21·7 |
| Greenhithe - - | 4·73 | 18·1 |
| Gravesend - - | 14·24 | 14·9 |
| Yantlet Creek - - | 5·09 | 10·4 |

The mean of our results obtained between July 1882 and January 1883, is as follows :—

| Place. | Number of samples examined. | Grains of suspended matter per gallon. | Percentage of volatile matter in suspended matter. |
|---|---|---|---|
| Teddington - | 8 | 1·72 | 14·1 |
| Hammersmith - | 6 | 1·78 | 15·7 |
| Westminster Bridge | 2 | 12·99 | 17·2 |
| London „ | 2 | 5·05 | 10·7 |
| Greenwich - | 30 | 5·04 | 20·5 |
| Crossness and Jenningtree point - | 7 | 5·20 | 20·6 |
| Erith - - | 20 | 5·06 | 18·1 |
| Greenhithe - | 19 | 3·04 | 11·8 |
| Gravesend - | 4 | 6·20 | 11·4 |
| Southend - | 1 | 2·85 | 9·7 |

(*To the witness.*) I think you have analysed, and in Table B have shown in more detail the results of samples taken upon different dates in the year 1882 at different points as regards the same thing, the suspended matter, the percentage of volatile or combustible matter, the percentage of fixed matter, the percentage of nitrogen in the total snspended matter, and the percentage of nitrogen in the volatile matter ?—Yes, it gives the composition of suspended matter a little more in detail in various parts of the river.

16,025. Is there anything more to draw attention to in that table ?—Yes, it shows that the suspended matter, even in the upper part of the river, is quite as strongly nitrogenous as that in the lower portion, it illustrates strongly what I said before, that the suspended matter is nearly the same throughout the whole length of the river, and there is a similar table in the Mud Inquiry which shows exactly the same.

16,026. (*Mr. Bidder.*) That is Table P in the evidence in the former inquiry which gives similar results as regards samples taken in the year 1879 ?—Yes.

(*Table B was handed in, and was as follows.*)

B.—MATTER suspended in Thames Water.

| Description. | % of volatile matter. | % of fixed matter. | % of nitrogen in total matter, | % of nitrogen in volatile matter. |
|---|---|---|---|---|
| From settling pond at Western Pumping Station, July 17/82 - - - | 12·98 | 87·02 | ·66 | 5·08 |
| Greenwich, mid stream, 2 feet from bottom, Oct. 12/82 (half ebb) - - | 13·6 | 86·4 | ·43 | 3·16 |
| Woolwich Arsenal, mid stream, 2 feet from bottom, Oct. 16/82 (half ebb) - | 15·07 | 84·93 | ·66 | 4·37 |
| Crossness Point, mid stream, 2 feet from bottom, Oct. 18/82 (half ebb) - - | 14·97 | 85·03 | ·67 | 4·47 |
| Erith, Sept. 7, 8, 9, 10, and 11, 1882, low water (surface) - | 21·63 | 78·37 | 1·22 | 5·64 |
| Erith, Sept. 4, 7, 8, 9, 10, and 11, 1882, high water (surface) - - - | 30·5 | 69·5 | 1·59 | 5·21 |
| Off Erith Causeway, mid stream 2 feet from bottom (one hour before high water) | 14·1 | 85·9 | ·43 | 3·05 |
| Coal House Point, mid stream, surface, 1½ hours, flood, Sept. 2/82 - - - | 13·8 | 86·2 | ·35 | 2·53 |
| Lower Hope, mid stream, 4 feet from bottom, 1½ hours before low water, Sept. 2/82 | 11·8 | 88·2 | ·29 | 2·45 |

16,027. We will now go to the results of the analyses of the water with regard to the deductions as to the amount of impurity at different parts of the river at different times; and now, I think, it will be convenient if we hand in diagrams which give in a graphic form the results of these analyses ?—Perhaps I might just say a few words about the construction of my book of tables. It is a very large book, but these tables are chiefly handed in in this great number to show the basis upon which the deductions afterwards are drawn. The whole essence of the table is concentrated into a few pages at the end giving the means; and I think it will be only necessary to refer to those beginning at page 103, those are means, the rest give the basis. *Dr. A. Dupré.* 20 June 1883.

16,028. You say up to page 103 is the detail, and from 103 onwards are the mean results, summarising that mass of detail ?—Yes, the tables are arranged in chronological order, giving always the analyses made on one day and topographically giving all the analyses made at one given spot.

16,029. The first table deals with oxygen absorbed from permanganate, which, as you explained yesterday, you regard as an indication of the amount of oxidizable or polluting matter present in the water ? — That is so.

16,030. At Teddington, on your Table No. 2 B, page 103, you start with a water which absorbs about ·1 of a grain per gallon ?—If the Commission will take the diagram marked 2 B, that gives Table 2 B in a graphic form. The diagram gives the longitudinal section of the river at its proper proportion, each place is put down at its proper distance.

16,031. That diagram represents the mean of the results during the three months of July, August, and September last ?—Yes, the river at Teddington begins with a small proportion of impurity, comparatively speaking, the impurity gradually rises to about twice that quantity, and diminishes again to less than the original quantity at Southend.

16,032. Rather more than twice, to put it strictly, and a little more than twice opposite Greenwich ?—It comes down to the purity that it was at Teddington again about Northfleet or thereabouts.

16,033. Before we go further, do I understand that in your judgment that shows that, by the time you get to Coalhaven or Northfleet, the river has done its work, and has destroyed the putrescible constituents of the sewage ?—No doubt.

16,034. And the water is restored to an equal condition of purity to what it had when it entered the tidal section of the river ?—Yes.

(*Chairman.*) Of course it does not follow that all the sewage discharged into it is destroyed, because, but for that sewage having been discharged into it, by the time it got down to Coalhaven, it might have been still purer. There is a figure in the table which shows that at London Bridge it is 183, at the tunnel it has got down to 132; that is to say, the water has purified itself in its course down to the tunnel.

(*Mr. Bidder.*) If you will look at the diagrams you will find in a good many diagrams there is a very curious accession of pollution in the neighbourhood of the bridges. What the cause of that is is perhaps difficult to say, but if you look at the diagram you will see a hump ranging between Westminster and London Bridge, showing that from some cause or other, there is a very palpable increase of pollution at that part.

(*Witness.*) It is always so, and the analysis shows the same result.

(*Mr. Bidder.*) And Dr. Tidy's analyses and tables show the same thing, as I understand.

(*Sir John Coode.*) But that is not applicable, I see, to Barnes Bridge.

16,035. (*Dr. Stevenson.*) Is not the river most impure at Blackwall; it is worse than at the outfall, is it not ?—On the average it is not so; but you will find, if we go into more detail, it is so at certain stages of the tide,—at high water or low water the increase of impurity is most marked in the neigbour-

*Dr. A. Dupré.*

20 June 1883.

hood out-falls, but if you take the mean of all, this vanishes amongst the rest.

16,036. (*Mr. Bidder.*) Turning to Table 2 C. and Table 2 B., where would you separate your results into high and low-water results, will you explain them?—Table 2 C. gives the mean result for high and low water for the months of January, March and May 1882, divided into high and low, and the figures show clearly that in the upper portion of the river it is very nearly the same at high and low water; whereas in the lower part it is distinctly worse at low than at high water.

16,037. And especially so at the neighbourhood of the outfalls?—Yes.

16,038. At No. 2 D. there is another period?—Yes; that shows the mean result for July, August, and September 1882.

16,039. There you have a worse result in the upper reaches of the river at high water, and a better result in the lower reaches of the river at low water?—Yes, and also here the same thing applies, that the impurity, starting from 1, goes up to about $2\frac{1}{2}$ as the maximum, and goes down to somewhat less than 1 lower down.

16,040. (*Dr. Stevenson.*) There is a point in Diagram 2 C., to which I wish to draw your attention, and that is, that at low water the maximum impurity appears to be above the outfalls?—It is just at the northern outfall at Barking Creek. Comparing the Diagram 2 C., which gives the earlier and cooler months of the year, with 2 D., which gives the same for the warmer months, it will be found that the river is purer in the summer than it is in the earlier spring months; and I think that will be shown again if we come to the free oxygen in the water.

(*Chairman to Mr. Bidder.*) What is the effect of this evidence? As I understand, this gentleman says this: I have done my best to ascertain, and I have ascertained, that very shortly after the discharge of the sewage into the water, the water appears to dispose of it in such a way that there is no more volatile matter in the river than is shown to have been existing in it before the sewage was introduced. He says. I do not say but what the river might be purer if no sewage were introduced into it, because that which is brought over Teddington Weir or which is found above bridge possibly would have got more purified by the operation of the river, if something else had not been introduced into it. Here are my diagrams and tables, and all that sort of thing, for the purpose of justifying that statement.

(*Mr. Bidder.*) That is so.

(*Chairman.*) And is it hopeful that we should have all those papers before us and go into them in that way? If Mr. Smith denies the correctness of the conclusion, let him cross-examine upon it. I declare I am in despair when I see these papers before me.

(*Mr. Lumley Smith.*) And I declare I am in despair at the idea of having to cross-examine upon them.

(*Mr. Bidder.*) What I proposed to do was simply to draw attention to the general results which these analyses show, and then, as your Lordship suggests, leave my learned friend to cross-examine.

(*Chairman.*) That is Dr. Duprè's evidence, and it is most valuable evidence; and after we have the statement to show how he comes to the conclusion, it is in vain for us to go through each one of these tables.

(*Mr. Bidder.*) I do not propose to go into them in minute detail, but to point to the things which the witness considers these diagrams are valuable as showing.

(*Sir John Coode.*) And to the salient points only.

16,041. (*Mr. Bidder.*) That is all. I do not think your Lordship will find me trespass beyond that. (*to the Witness*). I think we now come to another class of diagrams, which deal with the matter in another point of view; that is, the quantity of oxygen absorbed?—There is one diagram, I think, which is of considerable value, before we come to the oxygen absorbed, that is, 2 F. It has been stated that the river is getting progressively fouler. Now here I have a number of analyses at a year's interval at similar places, and in Diagram 2 F. the dotted line represents the year 1882; the full line represents the year 1883; and it will be seen that upon the whole, where the analyses are coincident, the river is, if anything, perhaps a little purer in 1883 than it was in 1882.

16,042. (*Sir John Coode.*) But what about the quantity of fresh water in the river at the respective periods; it is very material to know that?—I do not think there would be very much difference between the two.

16,043. (*Sir John Coode.*) That will be a question of fact?—No doubt.

(*Mr. Bidder.*) It is subject to that observation, no doubt.

(*Witness.*) It is subject to that observation, but that is one of the points which make for my contention. The river is so frequently flushed out that it does not get progressively more foul.

16,044. (*Mr. Abernethy.*) If you refer to Diagram No. 2 C., you will see that at Vauxhall, Westminster, and Blackfriars bridges, the diagram shows as almost identical the high and low water areas as regards results?—Yes.

16,045. Now will you turn to the next diagram, 2 D., at the same bridges you will find a very great difference between the high and low water results?—Yes; no doubt there was less fresh water coming down the river at that time.

16,046. (*Mr. Bidder.*) Now I think we may pass to the next series of diagrams which deal with the albuminoid ammonia. You told the Committee yesterday that a second way of testing the amount of impurity in the water, was by the albuminoid ammonia process, the tables relating to that begin on page 108, and the diagrams commence with No. 3 B. I will ask you, generally, do the results as shown in the tables, and as shown on the diagrams which plot out the albuminoid ammonia, give similar indications to your judgment with those that you derive from analysis as to the oxygen absorbed?—Practically they are identical.

16,047. I notice, taking the first diagram, No. 3 B., which is the mean result for July, August, and September, that it shows as the other did, that starting from Teddington you get an increase of impurity as you go down the river to the outfalls, diminishing again to less than its original impurity by the time you set to Southend?—Yes, that is so.

16,048. And it also shows curiously enough that very remarkable accession of impurity in the neighbourhood of London Bridge in the city, to which you have averted?—Yes, that comes out nearly always.

16,049. (*Dr. Stevenson.*) Are those waters which have subsided?—Yes, the analyses are taken after they have subsided always. Now the next two diagrams are analogous diagrams divided into high and low water, and they give the same result.

16,050. (*Mr. Bidder.*) They give the same result, that is to say, that the river above the outfalls is purest at low water, and the river below the outfalls is purest at high water?—Yes.

16,051. (*Sir John Coode.*) With regard to diagrams 2 B. and 3 B., a note in red says "mean result," but there is no reference to the period of the tide; is that the mean of observations taken over all periods of the tide?—That is the mean of all the analyses taken at any period of the tide.

16,052. (*Mr. Bidder.*) Diagrams 3 C. and 3 D. are divided into high and low water; you have first the mean of the whole, and then you have it divided into high and low water.

(*To the witness.*) Then there is one I should like to draw attention to before we pass from that series of diagrams. There is diagram 3 F., which is of considerable interest, because it bears upon the question of whether the condition of the river is getting worse or not. You have there plotted, I think, results from

analyses in 1878, 1882, and 1883, applying the albuminoid ammonia process?—Yes, the year 1883 is throughout the best.

(*Colonel Ewart.*) According to Table 3 C., the worst place is Deptford Creek.

(*Mr. Bidder.*) At high water Deptford Creek, and at low water Greenhithe.

(*Colonel Ewart.*) At Deptford Creek there is a storm overflow.

(*Witness.*) Yes there is a storm overflow there. I believe that at high water the maximum impurity goes up the river, at low water it moves down the river.

16,053. You do not attribute it to any local cause at Deptford Creek?—No.

16,054. (*Dr. Stevenson.*) I observe that at low water the maximum impurity is at Greenhithe; do you think the low water carries it down as far as Greenhithe?—In the cooler months you find that that is so when there is less oxidation, but in the summer months the maximum is at Jenningtree Point. I think that illustrates very strikingly the amount of oxidation that goes on during the summer, which keeps down the amount of impurity compared to the cooler months of the year.

16,055. (*Mr. Bidder.*) Is it that the impurity requires more oxygen in hot weather?—No, the influence is more active.

16,056. (*Chairman.*) In regard to 3 C., why is it so high at Galleons Reach?—That is the result of only one analysis of what may have been an exceptional sample. I think it must have been an exceptional sample, but having been analysed it was thought best to put it in.

16,057. One is inclined to think, from your diagram, that you have taken samples all the way along the line of the diagram?—Only where there is a break in the line. A break in the line indicates the point where a sample has been taken, and the exact position is given in the corresponding table, which is numbered and figured the same; you will find that in table 3 C.

(*Chairman.*) It is impossible, from this diagram, to conclude that there is a gradual worsening of the water, so to speak, from Northfleet to Coalhouse Point.

(*Mr. Bidder.*) The two analyses are at Northfleet and Coalhouse Point; all you can do to cover the intervening ground is to draw a straight line.

(*Witness.*) That is a necessary consequence of having analyses drawn at a certain point; there were so many diagrams already that it would have made a great increase in the number to have done it otherwise; but you will find the two days given quite separately.

(*Chairman.*) It is a little misleading to draw a line from point to point.

(*Mr. Bidder.*) It would have been best to put dots as well, but the eye wants a connecting link between them.

(*Witness.*) If your Lordship will look at diagram 2 G., that is a single day's experiment, two samples are taken at each place and analysed, one at high and one at low water.

16,058. (*Sir John Coode.*) That is a diagram of a class which, to my mind, is more valuable than giving mean results, because here you have different parts of the river upon the same day. I think it is a safer diagram to draw a conclusion from than those which are mean results, which extended over several months in a given year, or comparing one year with another year?—But there is also a diagram which gives the highest and the lowest result at each place. Diagram 3 E. shows for every place in the river the highest and the lowest result in albuminoid ammonia during the whole time.

16,059. (*Mr. Bidder.*) The worst and the best samples you get during those months?—Yes, during the year; and there is a corresponding table on page 111. Then if the Commission will look at diagram No. 3 G., that gives the albuminoid ammonia for a single day taking it right down the river.

16,060. Now I pass from that series of diagrams to the last series, which are diagrams No. 4 B., and so on; those are, I think, drawn to deal with the matter from the third point of view you mentioned yesterday, viz., examining the amount of free oxygen remaining dissolved in the water?—Yes.

16,061. If the amount of pollution introduced into water is very minute, the absorption of the oxygen from the air would prevent any reduction in the amount of free oxygen, would it not?—It would. The oxygen would be as rapidly absorbed from the air as it would be taken up by the polluting matter.

16,062. But if you introduce polluting matter more rapidly than the air will supply oxygen, by that process, you then get a diminution of the free oxygen in the water?—Yes.

16,063. That diminution being the measure of the amount of oxidation of putrescible matter which has gone on?—In a certain way.

16,064. In these diagrams, generally, I believe, you have assumed the percentage,—that is to say, full aëration, such as you find in the water at Teddington; you put down at 100?—Yes.

16,065. And then in your diagram, according to that scale, you have indicated the percentage of the full quantity of free oxygen which you find at the different places;—Yes, which was still left in the water.

16,066. I would like to ask you one question also before we go further. Do you agree with Dr. Tidy's view, that the fact of the oxygen having fallen sensibly below the full, or what we may call the standard, amount, is an indication that the river has lost its power of oxidation?—No, I think not. I think that is an entirely erroneous view. It proves that there is a very considerable amount of oxidation going on, and that the oxidation is so rapid that the water cannot recover the oxygen necessary from the air with sufficient rapidity,—that the lower the oxygen is, the greater, really, is the amount of oxidation actually going on.

16,067. (*Chairman.*) But that is not a difference with Dr. Tidy, is it?—Yes; he says that the river would have lost its power. See Dr. Tidy's answers to Questions 9957, 9958, 9960, 9961, and 9963.

(*Chairman.*) He says that water which, has lost its oxygen to a certain extent by reason of its having oxidised certain things, has less oxygen left in it than there was before.

(*Dr. Tidy.*) I think it right to say that I never suggested anything of the kind which the witness attributes to me.

16,068. (*Chairman, to the witness.*) Let me put it this way: if he said it, he is wrong?—Yes.

16,069. (*Mr. Bidder.*) Perhaps we may have misunderstood the effect of Dr. Tidy's evidence. Now, turning to the diagram No. 4 B., you could not do this all through in one day, so you have been obliged to make up this diagram by two days analyses?—Yes, it would have been impossible to go from Teddington to Southend, and analyse the water in one day.

16,070. This is an analysis, I understand, which has to be made upon the spot?—Yes.

16,071. (*Sir John Coode.*) There is a long interval intervening between them. There is one in August, one in September, and one in November. Would it not have been better if they had been taken all in the same month?—But that November one is done for the special purpose of comparison; it shows that when the weather is cool less oxidation goes on in the river, and in consequence more oxygen remains in the water, corresponding to the fact that we found more organic matter in the water during the cooler than during the warmer months. The long curve upon the diagram is made up from the samples taken on two days only, and it will be seen on reference to Table 4A, page 66, that the degree of aeration found at Westminster Bridge (the place common to both days) on the two dates differs but slightly, viz., 54·5 per cent. on August 9 at nearly high water, as against 48·6 per cent. on September 2 at

*Dr. A. Dupré.*

20 June 1883.

three-quarter flood, thus showing that the condition of the river did not differ much on these two days.

16,072. (*Dr. Stevenson.*) I suppose that, taking the different dates, if they are reduced to a common percentage of 100, they would still exhibit the same amount of oxygen?—Yes.

16,073. (*Mr. Bidder.*) Starting, with water thoroughly aërated, at Teddington, it diminishes, until opposite the outfalls it gets to its lowest, when there is only 20 per cent. of the original oxygen, and then rises at Southend again to its original complement of oxygen?—Yes, it does. At Southend the oxygen is given only as 96 per cent., but that is not due to the fact that any oxygen has been abstracted, but that the salt water dissolves less oxygen than the river water. It is here a water thoroughly aërated, but it is only 96 per cent. of what it would be in fresh water.

16,074. (*Sir John Coode.*) Because of the proportion of salt water which is mixed with the fresh?—Yes, so that really it comes again to absolute aëration.

16,075. (*Mr. Bidder.*) The general result you draw from this is, I think, that the effect of the introduction of the sewage from the metropolis has been entirely disposed of before you get to the lower reaches of the river?—Yes.

16,076. That the river has done its work in destroying the sewage?—Yes.

(*Chairman.*) I think Mr. Dibdin scarcely said that. I think he said there was still some sewage in the water which would prevent the water being drinkable.

(*Mr. Bidder.*) I think he said he could not undertake to say it was not.

(*Witness.*) I think his analyses do not go down so far as mine do. I think he stopped at Purfleet. At Southend the water would be undrinkable, because it is sea water.

16,077. (*Mr. Bidder.*) Now, going on to the next diagram, you have taken careful and complete observation at a particular place to show the state of the water at different periods of the tide?—Yes.

16,078. And that at an important place for the purpose of this inquiry, that is to say, Erith?—I went down on two days to Erith, and took samples of water at three stations upon the river, viz., at 200 yards from the south shore, at mid-stream, and 200 yards from the north shore.

16,079. What is the general result you get from your observations at Erith as to what happens in respect to the amount of free oxygen?—Starting at low water the proportion of free oxygen is at the minimum. As the tide goes up the amount of oxygen increases, and comes to the maximum at high water, when it has risen from about eight or ten per cent. to upwards of 40 per cent., or very nearly half. It goes down again as you approach low water. The degree of aeration here, as in other parts of the river varies exactly as the oxygen absorbed from permanganate and the albuminoid ammonia yielded were found to vary, all three methods, thus mutually supporting each other.

16,080. Now I will ask you a question about the south shore diagram, which is not so regular as the other; have you any explanation to give as to the apparent irregularities in the diagram and the results there shown?—When we made the experiment, I did not know it; but it appears that the engineering evidence clearly points out that there are some eddies at Erith upon the south shore which complicate the result, and sometimes bring the middle part of the river nearer to the shore or *vice versâ*, and there is an irregularity here which is not observable in the other diagram, because there are no eddies upon the other side.

16,081. Does this comparison of the oxygen in the water at Erith at low and at high water show you that a very large quantity of oxygen is added to the water in the interval between the two states of the tide?—Yes, I think it shows that the river is here beginning to overpower the polluting influence.

16,082. So that the stream which has gone down with its contribution of sewage that it has received from the outfalls, comes back with a fresh supply of oxygen, ready to deal with the next contribution of sewage?—That is so.

16,083. I do not know whether you are able to go a step further, and make a calculation as to the amount of oxygen which comes up upon a tide?—Taking the amount of water which passes up on a tide from Mr. Mansergh's statement, and taking the oxygen from my table here, I make it that as much as 233 tons of oxygen pass up the river in one tide, or 466 tons in a day.

16,084. That is to say, that a quantity of additional oxygen goes past Erith in the water as it goes up in addition to what was in the water when it went down?—Yes.

16,085. And is therefore there for the purpose of oxidation?—It is there to deal with the sewage which would require 100 tons of it.

16,086. (*Mr. Lumley Smith.*) Do you mean that that is the absolute amount of oxygen which passes one given point down the river, or is that the excess of what goes down?—It is the absolute amount that passes Erith upon a tide, and not the excess.

(*Mr. Bidder.*) To make that clear, because it is important that it should be made clear, is it a total of 40 per cent., or is it the difference between the 40 and the 8 per cent.?

16,087. (*Dr. Stevenson.*) Is that 233 tons the total amount of oxygen in the water that passes up at every tide?—It is.

16,088. (*Mr. Bidder.*) And it is not the difference between the 8 and the 40?—No. The mean quantity dissolved in the water is about 25 per cent., and as there are estimated to be 21,000,000,000 gallons of water passing up, each gallon containing half a cubic inch, the total quantity comes to 233 tons.

16,089. Then that 233 tons is based not upon the maximum observed, but upon the mean quantity?—Yes.

16,090. And that mean is about 25 per cent.?—Yes.

16,091. If we are to calculate the difference of what goes up as compared with what goes down, that is to say, comparing the 40 per cent. with the 8 per cent., it would be a bigger figure?—No; I do not think you can calculate that; that which I have stated is the quantity of oxygen in the water into which the sewage is discharged.

16,092. If you were to form the same calculation for the lower reaches of the river, inasmuch as the quantity of water is very much larger, you would get a larger quantity of oxygen?—Yes, as much as 10,000 tons of oxygen pass Southend upon the two tides, dissolved in the water, and only about 100 tons are necessary to burn up the sewage.

16,093. I think there was a slip which Professor Way made; he said provided the oxygen in the air was required to oxidise the sewage, the air of the neighbourhood would be irrespirable. I believe your analysis does not bear that out?—No; the effect would be so small that the difference in the air would not be perceptible.

16,094. Have you anything to say about the chlorine?—No; I think that Mr. Law has gone fully into that; I would only remark that the amount of chlorine upon the 14th of September seems, according to their experiment, to have been an exceptionally high amount; we have never had anything so high.

16,095. Taking the results of all these analyses, or these three different modes of dealing with this question, what is the general conclusion that you have come to as to whether the sewage does make the river in an unwholesome state, or whether the river is sufficient to deal with it?—I think they show that the river is quite capable of dealing with the amount of sewage discharged into it, without ever getting generally into a bad condition, and they show also, clearly, that the amount of sewage daily discharged is, upon the average, daily got rid of, otherwise there would be a progressive increase in the pollution which we have not observed, and we have observations after

an interval of five years. The sewage outfalls were opened, I think, in 1865; we have the first series of analyses in 1878 and the last in 1883, so that a five years' interval is a very considerable proportion of the whole, and yet they show no progressive increase, on the contrary, as I said, 1883 is slightly the best of all the years, showing, I think clearly, that the river is quite capable of disposing of the sewage that is discharged into it.

16,096 I should like to ask you a general question. Taking Erith, for instance, and the amount of pollution at Erith which your analyses indicate, what percentage of pure sewage, let us say added to the Teddington water, would represent that?—Something like 3 to 4 per cent.

16,097. That is at low water, is it not?—Yes.

16,098. And at high water?—At high water it come to considerably less; it often is less than 1 per cent.

16,099. (*Prof. Williamson.*) May I ask you a question for my own information. I understood you to have said that the river is capable of dealing with the sewage, and I understood that it was by oxidation, and that that is shown by the fact that there is not a progressive increase. Now, if the river were a lake instead of being a river, one could quite see that so much sewage being poured in in the 24 hours, there must be a corresponding quantity of oxygen combining with it to prevent an increase; but if it passes out of the river, the increase would not take place, as it would if it were a lake. But we have to consider whether there is usually present in the river a certain quantity of unoxidised sewage materials which smell. I do not quite see at present how your arguments bear upon that. Of course the sewage could not increase if there be daily a certain quantity going out of the mouth of the river. Supposing half of it were oxidised, or supposing a quarter of it were oxidised, still itwould, after a certain time, arrive at the maximum, and keep at that?—Yes, that would be so; but the contention on the other side is that it does decidedly go on getting fouler from year to year.

16,100. Then you do not contend that it is all oxidised?—No; I think a great part of it is disposed by animal life and vegetable life.

16,101. It goes out of the mouth of the river, does it not?—No, I do not think very much goes; I think it is disposed of before it gets to Southend.

16,102. It is eaten up?—Yes; the amount of infusorial life in the river in the summer is enormous.

16,103. (*Sir John Coode.*) Was there chemical evidence upon the other side to show that the river was getting worse?—Yes, Dr. Frankland stated that distinctly.

(*Chairman.*) I think Dr. Tidy does not differ from you; he does not say that the river is getting worse.

(*Dr. Tidy.*) I did not suggest that. From season to season I said, not from year to year.

(*Witness.*) I think you will find that Dr. Frankland said that it was getting worse progressively.

16,104. (*Mr. Bidder to the witness.*) Now you, in the course of making your analyses and taking samples, have been on the river upon many occasions, have you not?—I have been upon the river upon many occasions.

16,105. And especially with regard to the subject of this inquiry?—I have.

16,106. For instance last year, I think I may say, you were down the river a good many days?—I was 17 days upon the river in the summer during the months of July, August, and September.

16,107. Could you upon those occasions perceive any offensive or disagreeable smell proceeding from the water, excepting in the immediate neighbourhood of the outfalls?—No. We had always a large bottle with us and took samples repeatedly going up and down the river, shaking up the bottle to smell the water. And I repeatedly got into the small boat to get into the spray of the screw of the steamer, but outside the sewage stream I never smelt the river in any way to be offensive. The smell is very much the same really from Teddington downwards, it is a peculiar musty odour like wet straw; it is very faint and only perceptible when it is shaken up as I have described.

(*Sir John Coode.*) Were any of your samples taken after the "Princess Alice" disaster, when the river was stated to have been in an exceptionally bad condition.

(*Mr. Bidder.*) No. Mr. Dibdin's samples were, I think.

(*Mr. Lumley Smith.*) They were taken, I think, some time afterwards.

(*Mr. Bidder.*) We had some samples taken within either two or three weeks of the time.

(*Mr. Lumley Smith.*) They will be found on page 21 of Mr. Dibdin's table taken on the 24th of September.

(*Witness.*) My nearest time, I think, was in November of the same year. I was not upon the river earlier than that.

(*Mr. Bidder.*) I might mention, though we have not given it in evidence, but Mr. Dibdin tells me that what was called the "Lancet" Commission published a series of analyses taken immediately after the accident which give identically or substantially the same results as those which Dr. Dibdin gives, Nos 5 and 6 were taken at Beckton, and Nos 7 and 8 were taken at the place of the "Princess Alice" accident, by Dr. Dibdin.

(*Witness.*) I have frequently been down afterwards and examined the water at the spot where the "Princess Alice" went down, and I never found it offensive.

16,108. (*Mr. Bidder.*) Have you been there in hot weather in the summer?—I have been there in hot weather in the summer. I was there last year several times in the hottest part of the year.

16,109. You have been in the stream of the sewage itself, have you not?—Yes.

16,110. What do you find there?—The actual stream of the sewage in hot weather is very offensive and very nauseating, but it is not a very powerful or penetrating smell, so that it is very soon lost; and even if you go down in the actual sewage stream in ordinary weather, you lost the smell of the water in about 1,000 yards; you do not even smell it then, even if you shake up the bottle, but you lose it in the river in a boat within a few hundred yards. I was down there last Saturday, and I have never seen the sewage stream so well defined as it was on that day. At 2,000 yards down the stream you could see you were in the sewage stream because of the floating matter; you could not see the sewage, but only the floating matter.

16,111. (*Chairman.*) What is it you smell, is it a gas?—I think it is an actual gas, carburetted hydrogen, or something of the kind, which is given off.

16,112. (*Mr. Bidder.*) But there is something more than carburetted hydrogen in that fœtid smell, is there not?—I think that is the chief, but some compound ammonias are given off. It is a very complex mixture; but even on Saturday at 2,000 yards, as I was saying, the smell in the water was gone.

16,113. (*Prof. Williamson.*) Do we understand you rightly to say that at 2,000 yards from the outfall the sewage stream which you can see does not smell?—You can see that the sewage stream is passing there by the amount of floating matter in the water; you do not see the actual sewage passing down, but you see small pieces of cork and vegetable matter, and even small pieces of excrement.

16,114. One witness stated that he could trace the line of demarcation between the sewage water and the rest of the river for some way down, as if the sewage did not mix; what do you say to that?—I have never seen that beyond 500 or 600 yards.

(*Mr. Bidder.*) There is no dispute that for a certain distance you can see the sewage.

16,115. (*Prof. Williamson.*) We were told that a boat was moored so as to be half in and half out of the sewage stream?—Yes, you can do that when you are 200 yards off the outfall, when it is very distinct

*Dr. A. Dupré.*

20 June 1883.

indeed; but at the northern outfall you lose that when the stream from Barking Creek comes in and pushes it out further into the centre of the river.

16,116. (*Chairman.*) Do you smell it at the Reservoir?—Yes, but it is so faint a smell that at 200 or 300 yards off, even if the wind is blowing towards you, you lose the smell. It is a nauseating smell when you are in it, but it is not a penetrating smell, it is not carried to any distance.

16,117. (*Mr. Bidder.*) Do your general observations as well as analyses confirm you in the view that within a few hundred yards the sewage very rapidly mixes with the general body of the river water?—It mixes very rapidly indeed. The great rapidity with which the sewage mixes with the water comes out very strongly in Dr. Tidy's Table No. 6, in which there are a number of analyses of sewage taken at the Crossness Outfall; they were taken at the outfall while the sewage was discharging, and the amount of organic carbon is scarcely ever much higher than it is in the river itself, showing how very rapidly, even at the outfall, the mixture takes place.

16,118. (*Sir John Coode.*) You mean in the filtered liquid?—Yes.

16,119. (*Mr. Bidder.*) I must ask you to go back to another matter. Have you observed upon that part of the river, from the neighbourhood of the outfalls down towards Erith, often very distinct and offensive smells which might reasonably give rise to the complaints of people who think they smell the river?—Yes; one notices a great many excessively offensive smells from the factories.

16,120. Have you found these factory smells, according to your observations, more or less penetrating in the sense of reaching a distance than sewage smell?—They are very much more penetrating; you can smell them sometimes 2,000 or 3,000 yards off powerfully, so as to be offensive.

16,121. And besides that I think there is a good deal of material carried in boats on the river of a very offensive character?—There is a very great deal of slaughter-house refuse and manure, and various offensive matters, rotten fish for making the manure, for instance, and the smell from those is sometimes really almost indescribably offensive.

16,122. I must ask you just to deal with another topic of discussion. There have been a good number of witnesses here, unscientific persons, who have asserted that the mud in various places is little more than deposited sewage, and is quite different from ordinary river mud. You have analysed the mud upon a great many occasions, have you not?—I have.

16,123. Both for the last inquiry and since?—Yes.

16,124. What is the result of your analysis of the mud at Erith and the neighbourhood up and down the banks of the river as showing whether it is or is not ordinary river mud?—The result is that all along the river, from Teddington downwards, the mud, wherever there is mud, is very much the same. If there is a differencee the mud of the upper part of the river is slightly fouler than that of the lower portion of the river; for example, almost the worst bank in the whole river is at Westminster, which is very bad.

16,125. (*Sir John Coode.*) On which side of the river at Westminster is that bank?—It is below the Houses of Parliament.

16,126. (*Dr. de Chaumont.*) Do you agree with the opinion of Dr. Frankland, that the river is getting progressively fouler now above the outfall within London itself?—Decidedly not; all my evidence goes the other way.

16,127. Dr. Frankland says at question 10,686, "After the opening of the outfalls the river remarkably improved in purity; but since that time, from soon after the main drainage outfalls were opened, the purity of the river in London has been decreasing" Do you agree with that?—No, I do not. That was the answer I was referring to when I gave my evidence just now.

16,128. (*Sir John Coode.*) How far below the Houses of Parliament is this bank you spoke of just now?—It runs along the Houses of Parliament from Westminster Bridge upwards. I do not know how far it extends.

16,129. Do you know anything of a bank under St. Thomas's Hospital which used to accrete very rapidly?—Yes, I have analysed that too.

16,130. I have heard the late Mr. Leech, the engineer to the Thames Conservancy, speak of that bank as a difficulty; was that a nuisance?—I would not say that, but chemically it was very bad. I have not been on the bank when it was exposed.

16,131. (*Chairman.*) I suppose you would say it would not be smelt from the hospital?—I never heard that they complained about it in the hospital.

16,132. (*Mr. Bidder.*) I believe you wish to hand in a table with respect to this mud bank at Erith?—Yes, I beg to hand in Table C.

*The table being handed in, was as follows:*

C.—Samples of Mud from Bank at Erith.

| Description. | Percentage of Volatile Matter. | Percentage of Fixed Matter. | Percentage of Nitrogen in Mud. | Percentage of Nitrogen in Volatile Matter. |
|---|---|---|---|---|
| Pier, December 22, 1878 (surface) | 11·96 | 88·04 | ·44 | 3·68 |
| Causeway, August 5, 1882, near water line, one-third flood (surface) | 15·03 | 84·97 | ·59 | 3·92 |
| Causeway, August 5, 1882, near water line, one-third flood (six inches deep) | 16·63 | 83·37 | ·62 | 3·72 |
| Causeway, August 31, 1882, low-water line, very low water (surface) | 8·08 | 91·92 | ·24 | 2·97 |
| Near Balast Wharf, August 31, 1882 (surface) | 9·16 | 91·84 | ·23 | 2·57 |
| Halfway between pier and Easton and Anderson's low-water line, December 18, 1882 (surface) | 12·88 | 87·12 | ·36 | 2·79 |
| Halfway between causeway and pier, low-water line, December 18, 1882 (surface) | 12·00 | 88·00 | ·51 | 4·17 |

16,133. (*Mr. Bidder.*) This all relates to Erith?—Yes, because the other banks have been so often analysed that I took this to show that the bank at Erith does not differ in any way from the banks in other parts of the river.

16,134. When you refer to other analyses you are speaking of the analyses in the Mud Inquiry?—Yes.

16,135. Does the analysis of the Erith bank show it to be practically of an identical composition with the mud banks up and down the river, as analysed by you upon the former occasion?—It does, decidedly.

16,136. (*Chairman.*) You limit it to the bank at Erith?—Yes.

16,137. Those are the samples you took, and you know otherwise of the composition of the mud at other parts of the Thames, and you say those correspond?—Yes.

(*Mr. Bidder.*) After page 1065 of the Mud Inquiry, there is a series of tables, and, perhaps, the best one of all is Table U.

(*Witness.*) Yes, that gives the proportion of nitrogen, which is the important thing, and that compares with the last figure in this Table C.

16,138. That table is arranged by progressive pollution without regard to locality, and a glance at the places show that the amount of pollution is quite irrespective of the part of the river; indeed, a good number of the worst are up at the higher part of the river?—Yes, the greater number of the bad ones are up at the upper part of the river.

(*Mr. Bidder.*) Now there is one question which perhaps my learned friend could answer, which would save a great deal of time. Of course, strictly, all this mass of samples ought to be proved; but it would be absurd to keep the Commission here while they are proved in detail; and I should be glad if my learned friends would say whether they are content with them as they stand, or wish them to be proved.

(*Chairman.*) If Mr. Lumley Smith would say he is

content, I should be glad; if he does not I am inclined to say we are. There can be no doubt, for my own part, I would not admit a doubt,—as to the bonâ fides of either party in this matter—they are both public bodies.

(*Mr. Lumley Smith.*) There are one or two samples in 1878 about which one would like to know a little more, because there is a little uncertainty as to what they were; but I say, taking the samples as they stand, no doubt it is impossible to prove all these samples.

(*Mr. Bidder*) Then perhaps it may be taken that unless there is anything that my learned friend wants particularly to draw attention to, the samples need not be verified.

(*Mr. Lumley Smith.*)—Yes.

Cross-examined by Mr. Lumley Smith.

16,139. First of all, I want to ask you a general question or two about these processes. It was suggested by Dr. Dibdin that Wanklyn's method was not to be depended upon—what is your opinion as to that?—I think, when properly performed, it is fairly reliable.

16,140. Which do you consider the more reliable, the Wanklyn or the oxygen process?—My experience is, that if they are both worked well, they give, as a rule, analogous results. I really would not like to say which was the most reliable—in certain cases, one might be the better, and in other cases the other might be the better.

16,141. You have given in your tables the result of your oxygen test, and the result of your albuminoid ammonia test?—Yes.

16,142. Is it not the fact very often, that in the same place you find different results—it is not a rule of three sum. Supposing you compare water at different places, the amount of oxygen which one requires does not show the same amount of impurity by the oxygen test, as would be shown comparing the two places by the ammonia test, does it?—Not always, strictly speaking; but, broadly speaking, they do show the same result.

16,143. If you turn to page 59 of your book, you will find a couple of samples which have pretty nearly the same amount of albuminoid ammonia, that is to say, No. 386, in which the albuminoid ammonia is ·036. Now, if you go a little way back to No. 382, you will find the albuminoid ammonia is ·038, so that judging by that test, they are pretty nearly equally bad or equally good?—Yes, that is so.

16,144. Now we will go to page 33, and compare the amount of oxygen which those two samples take—No. 386 takes ·314?—Yes.

16,145. And if you refer to No. 389, you will find it takes ·118?—That is so.

16,146. So that, although these waters are pretty nearly equal, as shown by the albuminoid ammonia process, when you come to test them by oxygen, one is not so bad as the other; and the worst according to the albuminoid ammonia comes out the best when tested by the oxygen process—is not that so?—The three quarter ebb is, in regard to oxygen absorbed, the worst, and in the albuminoid ammonia test the high water is a trifle the worst.

16,147. The difference is very considerable, if you take the oxygen test, and very inconsiderable if you take the albuminoid ammonia test?—Yes, that is so; but if you take the series, you will find that they follow very much the same order.

16,148. Will you turn to page 50, and look at Teddington — sample 463 — that shows albuminoid ammonia ·0269?—Yes.

16,149. Then will you turn to page 25, and, I think, you will find the amount of oxygen required by that sample is ·325, is it not?—Yes.

16,150. Now, if you will pass on to another figure, if you will go to page 59 and take Erith, No. 389, you will find there the albuminoid ammonia is ·038, that is so, is it not?—Yes, that is the same.

16,151. Then, if you turn back to the oxygen test for that sample, at page 33, you will find ·118?—Yes.

16,152. Is not the result of that this, that the Teddington sample, which had the smaller amount of albuminoid ammonia, required three times as much oxygen to oxide it as was the case in the Erith sample?—Not quite three times.

(*Chairman.*) Will you allow me to ask you, does that show anything more than that there was a mistake in the experiment?

(*Witness.*) No, I think not.

(*Mr. Lumley Smith.*) We dispute the Wanklyn process as being one to be relied upon. We also dispute to a certain extent the oxygen process as being good; and here you find that if you take two figures at random, they give opposite results.

(*Chairman.*) You have taken two specimens.

(*Mr. Lumley Smith.*) And, no doubt, we could produce more.

(*Chairman.*) But in a general way they tally, do they not?

(*Witness.*) The explanation is very simple. The two processes, neither of them profess to give the absolute amount of organic matter—they must be compared with themselves, and not one with the other. You must not compare the result by the oxygen process of different kinds of matter with the albuminoid ammonia process, otherwise you will get discordant results; but you must compare the oxygen process right through and see what you get, and then compare the albuminoid ammonia process right through and see what you get from them all, and you will then find the conclusions identical.

(*Mr. Lumley Smith.*) But I showed you that the albuminoid ammonia showed the two waters to be very much alike, whereas the oxygen process showed them to be very different.

(*Chairman.*) It may be an error of manipulation.

(*Prof. Williamson.*) I think the discrepancy of the figures can hardly be said to be a mistake in either case, because each process determines something different from the other. They each attack the question from a special side, and the quantity of organic matter can only be judged by a sort of guess work. Each determination may be perfectly correctly made within very narrow limits of accuracy, and yet they may differ from each other so that each of them gives rather a sort of approximation to the truth than an accurate result.

(*Dr. de Chaumont.*) Would it not also indicate that the kind of organic matter was different in the two cases?

(*Witness.*) No doubt it was more animal matter in one case and vegetable matter in the other case.

16,153. (*Dr. Stevenson.*) Do you know any process which gives anything more than a guess?—I do not know any process which gives more than a guess.

16,154. (*Mr. Lumley Smith.*) If this is nothing more than material for guessing at the truth, I do not know that I need carry it much further. (*To the witness.*) Are the diagrams you put in to-day based upon a single or upon a number of samples?—They are based in a general way upon a number of samples.

16,155 Upon what number in a general way?—In some cases from 20 down to three, and in a few cases upon only one.

16,156. Does that appear upon a diagram?—No, but it appears upon the tables—you can easily find it out in the tables.

16,157. The table is a catalogue of all your samples?—The table is a catalogue of every sample taken.

16,158. Supposing you had a point shown upon your diagram at Erith, or elsewhere, as the case may be, do you mean to say that by working through the tables you can find out how many samples were taken at Erith?—Yes.

16,159. It is the mean of the calculations, is it?—Yes, it is.

*Dr. A. Dupré.*
20 June 1883.

16,160. And you have not shown upon your diagram at any particular point of what number of samples it was the mean?—That is not shown.

16,161. That would make a material difference, would it not, the samples vary considerably at different places and different times?—Yes, but the table clearly shows that if you turn to the analysis showing a sample at any particular place, or if you turn to the diagram showing the highest and lowest results, that will show you at once how much they differ at any particular place.

16,162. Are all your highest and lowest together?—Yes, they begin on page 50; they are arranged topographically; you have all taken at one place, given together.

16,163. Am I to take it that upon your diagram where you have more than one sample, you have universally taken the mean?—Yes.

16,164. You have one diagram here which is called No. 4 C, which shows the percentage of the free oxygen dissolved in the Thames water off Erith pier?—Yes; they are all given on page 68.

16,165. Your diagram does not state the year in which those two were taken?—That is so; they were taken on August 31st and September 1st 1882.

16,166. You have taken these two consecutive days for what purpose?—Because I wanted to get a clear picture of the variation in the amount of oxygen.

16,167. In two consecutive days?—There is a limit to one's time. I should have liked to have had more than two; but I could not.

16,168. You think that is a fair sample?—Yes; I think it a very fair specimen.

16,169. Do not you know that Mr. Dibdin's in taking these two consecutive days founded a diagram upon the fact that there had been very heavy rain, and that it had scoured out the river, and that diagram No. 4 of Mr. Dibdin's shows that it had been a very exceptional state of things?—I think this diagram confirms that, because you will see that on August 3d it was a high tide, and that in every case the high water comes to a better figure of oxygen.

16,170. But I am pointing out that if you are taking these as an ordinary sample of the Thames, you have selected a very exceptional time, because Mr. Dibdin stated he took these samples at a very exceptional time?—First of all, let me say, there was no selection in the matter; we went down the river because we happened to have leisure upon those two days. I made no selection whatever, for I did not know that there would be a high tide upon those days.

16,171. It so happens at all events that that was a day upon which there was an exceptionally high tide which scoured out the river?—Yes, no doubt, August 31st was.

16,172. According to Dr. Dibdin's diagram, there was about the same amount of chlorine on the two consecutive days; but the amount of albuminoid ammonia varied very much?—I do not think they did vary very much. I think if you turn to the other analyses you will not find that they were especially good days; on the contrary, they were rather bad days, both of them.

16,173. Before I pass from that, I think you stated that sea water would not dissolve much oxygen?—It will not dissolve so much as fresh water.

16,174. What samples did you take of sea water; the only one which I can find is at page 64 of your book, and there I find that at Southend at nearly low water you found 96 parts of oxygen, whereas 100 is your fully saturated quantity in water?—In fresh water.

16,175. You take fresh water, when saturated, as being 100, and here I find at Southend Pier it is 96, which is nearly 100?—It is nearly 100, but it is not quite; it is so much less, because sea water dissolves less than fresh water. I took that identical sample to the laboratory, and estimated how much oxygen I could add to it, and I found that it was 95 in the laboratory which is within the limits of experimental error.

16,176. Have you any samples of pure sea water?—I have this identical Southend sample which I took home to the Laboratory, and ærated.

(*Chairman to Mr. Lumley Smith.*) Has anybody said that sea water does take as much oxygen as fresh water?

(*Mr. Lumley Smith.*) We put in some figures showing the amount of oxygen that was to be found in the sea water.

(*Chairman.*) Is it different from what Dr. Dupré says?

(*Witness.*) You do not get so much, but very nearly the same in the sea as the fresh water.

(*Chairman to Mr. Lumley Smith.*) Supposing we should agree with Dr. Duprè instead of agreeing with your figures, would it make any difference in the decision we should come to, do you think.

(*Mr. Lumley Smith.*) Perhaps not; but I think an argument was based upon it in this way,—that where there was a certain quantity of oxygen in the river, as sea water takes very little oxygen, it was said that they had the right to assume that the rest of the oxygen was consumed in burning up the sewage. Now, as sea water does take the oxygen, it may have gone into the sea water and not into the sewage.

16,177. (*Dr. Stevenson to the witness.*) Do saline solutions generally take up as much oxygen as fresh water?—No, they do not. And I may say that this is an actual experiment, whereas the figures upon the other side cannot be controlled, because unfortunately there is never a temperature given; but in my tables the temperature is always given. The amount of oxygen in water varies greatly with the temperature, and you can draw no conclusion unless the temperature of the water is given.

16,178. (*Sir John Coode.*) Four per cent. is the margin of difference between the two?—Yes; that is about it.

16,179. (*Mr. Lumley Smith.*) Now I will ask you about the quantity of matter that goes into the water. I am not going into the dry matter and the wet matter, and so on, but I want to know whose experiments you based your conclusions upon?—I took Professor Way as the authority for the one ounce in the fœces, and I think that is a very fair allowance.

16,180. There is no contention about that, that the dry matter of fœces is one ounce; but now you say that of that, about ·14 is mineral, and ·86 is organic; that you gave us yesterday?—Yes, it is so; but it varies.

16,181. Now in calculating the amount that goes into the river, you seem to me to omit the mineral part; that all goes into the river, as well as the organic, does it not?—But I only stated that which was the polluting matter; common salt will not be treated as a polluting matter.

16,182. It does go into the river; but you consider that we ought only to trouble ourselves with the organic part which you make ·86?—Yes.

16,183. (*Chairman.*) That you say is burnt up?—Yes, it is.

16,184. Reduced to its constituent gases?—Yes, chiefly to carbonic acid, nitrogen, and ammonia.

16,185. And would escape?—Yes.

16,186. (*Mr. Lumley Smith.*) Do you know Mr. Simon's book on Animal Chemistry?—I cannot say that I know it.

16,187. I see at page 372 of the edition of 1846, he gives analyses of human fœces according to Berzelius, and I want to point out to you that he makes the salts as being 12 parts out of 267?—You will find it given in some cases up to 15 and 20 per cent: it varies very largely.

16,188. He makes the minerals more than you do, and the organic matter more?—Yes, but the difference would be a mere fraction.

16,189. (*Sir John Coode.*) The organic matter is all that you thought necessary, at any rate?—Yes.

16,190. (*Mr. Lumley Smith.*) Now we will come to the urine, upon which there is a larger difference

between you. There was a great discussion in Dr. Tidy's evidence (I will not go through it all over again, but it begins at question 10,440) as to the amount of urine which ought to be taken per person, as to whether it should be taken at 40 or 60 ounces, how many ounces have you taken?—I never calculated it out into the quantity of urine per head of the population, but only the solids per head.

16,191. You gave us 1·68 as solid matter coming from the urine, now will you tell me from whose book you got that 1·68?—I think it is taken from Woolf and Lehmann.

16,192. Mr. Bidder told us, and I think it appears in the evidence, that Röder and Eickhorn took their figures from Woolf and Lehmann?—Yes.

16,193. So that Woolf and Lehmann are the foundation of the inquiry?—Yes; I have looked through a number of authorities, and I will not be sure, but I believe it is mostly if not entirely based upon Woolf and Lehmann. I have here "Liebig's Agricultural Chemistry," and I suppose I cannot well quote any higher authority on such matters than he. Now Liebig gives the total amount of what he calls the "dust-dry" residue of the liquid and solid excrement of one million people, men, women, and children, as 45,000,000 lbs. per year, which is somewhat less than two ounces per day.

16,194. Will you give me the reference to Liebig's book, because I do not want to discuss it here?—(*The book was handed to the learned counsel.*) He has given it at 2 ounces, whereas I have taken it at 2·6 ounces, which is materially higher.

16,195. You cannot tell me, however, what the quanity of urine is based upon per day?—No, I cannot.

16,196. The page of the German edition (Brunswick, 1865) of Liebig's book that you have quoted is 292?—Yes; I think it is the latest edition that was published under Liebig's supervision.

16,197. Now, with regard to this theory of yours about the river every day burning up the sewage, that is based, as I understand, upon a comparison of the free oxygen one day with another, putting out of account all displacement and all mixing?—No, it is based upon analyses five years apart.

16,198. That is based upon your 1878 samples?—Yes, and upon the 1882 samples, and upon the 1883 samples.

16,199. But it is merely done by comparing the quantity of oxygen that is found in the water upon one day with that found on the next, is it not?—No; it is based upon the fact of the impurity found in 1878, 1882, and 1883, and I find that the water in 1883 is purer than in either of the two preceding years.

16,200. Tested, in the way you have done it, by the amount of albuminoid ammonia?—And by the amount of oxygen absorbed in the two years.

16,201. (*Sir John Coode.*) To judge fairly of that, I think we ought to have some idea of the amount of water in the river, because the year 1882 was a wet year?—No, I think 1882 was not an exceptionally wet year.

16,202. I think there are no oxygen experiments in 1882?—Yes, they are all in 1882. Now I do remember something of the weather in 1878. There are two days when I was going the greater part of the way down the river, and in January, a short time before I went, there had been very heavy rain—a flood, in consequence of which the river was upon that day decidedly better; but upon March 4th, there had not been any rain for some time previously, and the river was not in flood at all.

Cross-examined by Mr. Beaumont Morice.

16,203. Upon your diagram 3 C., you show that the river was in its worst state down at Northfleet; it gets very low down there?—If you go to Northfleet it is very considerably better; I think you must be referring to Greenhithe.

16,204. Do you know how far the sewage goes down the river upon an ebb tide?—That is to say, I suppose, the water into which the sewage is discharged; it goes down about 12 miles, I believe.

16,205. From your investigations could you say whether there is any sewage at low water below Greenhithe?—I should say a very small proportion.

(*Chairman to Mr. Beaumont Morice.*) What do you mean by that: undiluted sewage?

(*Mr. Beaumont Morice.*) No, sewage still remaining, going down the river upon the ebb tide.

(*Chairman.*) Of course it is going down the river; whatever comes out of the outfalls must go down the river; but do you mean in an undiluted condition?

(*Mr. Beaumont Morice.*) No, still in the water.

(*Chairman.*) I do not understand you; it goes down the river until it gets out of the river.

(*Mr. Beaumont Morice.*) I mean, so that you can detect it.

(*Witness.*) At Purfleet you can detect it, but not by any smell, there is not the slightest smell there.

(*Mr. Beaumont Morice.*) I ask you, can you detect the sewage in the water at Greenhithe at low water in such a state as to be injurious?

16,206. (*Chairman.*) Is the river in such a state that you can detect the sewage in it?—I think you can detect it by taking the contrast between high and low water, you can see that the water at high water is still purer; but otherwise, than by analysis, you cannot detect it.

16,207. If you smell it, can you detect it?—No.

16,208. If you take it up in a bottle and shake it can you detect it?—No.

16,209. What must you do in order to detect it?—You must analyse it very carefully.

16,210. What would you find upon analysis?—You would find a little more albuminoid ammonia, and you would find that it absorbed more oxygen from the permanganate than it would otherwise.

16,211. So the volatile matter has not been destroyed entirely by the action of the oxygen in the water?—Not entirely.

16,212. (*Mr. Beaumont Morice.*) You state that you do not consider that the river is increasing in its pollution as as far you have observed?—I have observed it from Teddington to Southend.

16,213. Do you speak chemically, or from ordinary observation?—I speak both from chemical experiment and from ordinary observation.

16,214. How far does that extend, all the way down the river?—Yes, all the way down the river. It naturally fluctuates sometimes from week to week, but taking one year with the other, there is no variation.

16,215. I understand you noticed it often last year, in 1882?—I have been often on the river.

16,216. But last year was an exceptionally unfavourable year for the river, was it not, as it was cold and wet?—I do not think so. If you take the Astronomer Royal's Tables, I think you will find that the temperature was within a tenth of a degree or so of the average, and the rainfall was very little beyond that of an average year.

16,217. But have your observations extended over a series of years—eight or ten years running?—No, not running.

16,218. You stated that you went close down to the sewage?—I did.

16,219. Could you distinguish between that smell and the factory smell?—Yes, if you are close to the sewage.

16,220. You can distinguish between the sewage and the factory smells?—Yes, you can do it, but only when you are close to or in the sewage.

*Dr. A. Dupré,*

20 June 1883.

Re-examined by Mr. Norman Bazalgette.

16,221. I want to ask you whether the samples, from which you draw your annual mean, are fair average samples, or whether they are taken on any particular day or any particular month?—They were taken at random.

16,222. So that the results are not likely to be affected by any exceptional circumstances applying to a particular day?—No, I do not think they would be.

Examined by the Commission.

16,223. (*Chairman.*) I understand you say that the sewage in the river brings down with it matter which is mineral, or, I suppose, insoluble, and not to be dissipated in some way or other, and matter which is capable of being resolved into gases and escaping and being innocuous?—Yes.

16,224. I understand you to say the water has the property of acting upon the sewage brought down in such a way that it does resolve a large portion of it into its constituent gases, which are dissipated and do no harm?—Yes, that is so.

16,225. Then as to the solid mineral matter, Dr. Dibdin tells us it was mainly salt?—Yes, it was mainly salt.

16,226. What would that do?—It would be dissolved in the water; but it would be a mere minute fraction compared to the salt which came in from the sea.

16,227. You say the effect of that is that although the water smells very badly when it is stationary in the reservoir, and when it is poured out into the river, yet that at a distance of 1,000 yards no smell is perceptible, and that at a distance of, say, 10 miles, at Northfleet or Greenhithe, you could only detect that sewage had been poured into the river by analysis; is that what you say?—It is.

(*Chairman.*) I would like to ask Dr. Tidy whether he assents to the evidence you have given. (*To Dr. Tidy*) Do you differ from that?

(*Dr. Tidy.*) Somewhat, my Lord.

(*Chairman.*) That is to say, you would make out that the oxygen had more work to do, or that there was less of it to do the work, and that the smell continued longer.

(*Dr. Tidy.*) That you could smell it at a much greater distance—a very much greater distance.

(*Chairman.*) I think we may say that the difference between the distinguished gentlemen who have been called on the one side and on the other, is what you may call quantitative and not qualitative, more than anything else.

(*Sir John Coode.*) It is a question of degree.

(*The Witness.*) I would say, I believe that if you blindfolded any person, and took him down the river, he could point out to you every foul factory to the windward and every foul boat he passed by his nose, but he would not know when he passed the outfalls.

16,228. (*Chairman.*) You say you have analysed the mud, and it is not worse in the neighbourhood of the outfalls than what you call the average mud of the river?—I do.

The witness withdrew.

(*Chairman to Dr. Tidy.*) Having heard that statement, do you differ from it?

(*Dr. Tidy.*) I entirely differ from it.

(*Chairman.*) Do you say there is much more sewage in it than Dr. Dupré makes out.

(*Dr. Tidy.*) Very much more.

(*Chairman.*) More mineral constituents.

(*Dr. Tidy.*) No. I refer to nitrogenised matter which has not been oxydised, and which can undergo putrefactive decomposition.

(*Chairman.*) Which is undergoing that upon the mud.

(*Dr. Tidy.*) Which may undergo it.

(*Chairman.*) Which, as it is exposed upon the mud, gets oxidised.

(*Dr. Tidy.*) It undergoes decomposition, is not oxidised. With regard to putrefaction that is not oxidation. When we have oxidation we have harmless inoffensive bodies formed; when we have a body putrefying, we have it broken up, and offensive gases given off. In the case of oxidation, the hydrogen becomes water and the carbon becomes carbonic acid.

(*Chairman.*) One knows that rust is oxidation.

(*Dr Tidy.*) Yes.

(*Chairman.*) There is nothing foul in that.

(*Dr. Tidy.*) No, not in that case.

(*Chairman.*) Does not the organic matter get oxidised in the mud.

(*Dr. Tidy.*) Very likely a small quantity does, but its tendency is to break up and decompose into other products.

(*Chairman.*) Then you ought to smell it.

(*Dr. Tidy.*) Decidedly.

(*Chairman.*) Then all you have got to do is to smell some of this mud.

(*Dr. Tidy.*) Not necessarily; you may not smell it at the moment, but after a time it will smell.

(*Mr. Lumley Smith.*) There was some evidence as to the mud which, though it might not smell at the time, yet after two or three days it would smell.

(*Dr. Tidy.*) It would.

(*Sir John Coode.*) Is the process of oxidation ever going on simultaneously with the process of putrefaction.

(*Dr. Tidy.*) It might.

(*Sir John Coode.*) I should have thought the oxidation was always going on in a degree.

(*Dr. Tidy.*) I should think in the case of mud exposed, the tendency would be to putrefaction rather than to oxidation.

(*Sir John Coode.*) No doubt, but my question is, While putrefaction is going on does oxidation go on to any extent, or does the putrefaction go on for a certain stage, and then oxidation begins?

(*Dr. Tidy.*) I think it is quite possible for them both to go on together, but not upon the same particles.

Sir Frederick Abel, C.B., F.R.S., called in and examined.

*Sir F. Abel, C.B., F.R.S.*

16,229. (*Chairman.*) While we are upon this point, do you mind telling us what is putrefaction?—It is what chemists call a "metamorphosis," a change in the arrangement of the components of a chemical compound of animal origin containing nitrogen, resulting in the production of a class of comparatively simple bodies, some of which have very powerful odours indeed, and those produce what we know as putrifying smells or odours. Those bodies are transient in their character, and are eventually converted into the most simple products, which are, generally speaking, gaseous, and escape into the air in the ordinary course.

16,230. When they talk of burning up by oxygen, that is a sort of addition of oxygen, oxygen is added, but in putrefaction is there no addition?—No, there is no addition to the substance, it is a transformation which takes place under conditions of temperature, and other conditions favourable to that change.

Examined by Mr. Norman Bazalgette.

16,231. Before taking you through your proof, I believe you have had before you samples of mud which have been taken from the river and been placed in the laboratory?—I have.

16,232. After having been placed in the laboratory, did you find that they became putrescent and then emitted an unpleasant smell?—That is so.

16,233. Is that a characteristic of Thames mud or of all muds?—That is characteristic of any mud which contains vegetable matter.

16,234. (*Chairman.*) Or animal matter?—Yes, or animal matter, but that is comparitively rare in muds; so I did not specify it.

16,235. (*Mr. Norman Bazalgette.*) I believe that the analytical results which Dr. Dupré put in in the form of tables have been the joint work of yourself and him?—Yes, they were.

16,236. Do you agree in the general conclusions which have been drawn from them by Dr. Dupré?—In a general way, I do.

16,237. Do you agree with the chemical methods that have been employed by Dr. Dupré to get to his determinations?—I agree with the views expressed by Dr. Dupré with regard to the value of these methods. I may perhaps state shortly, as has been already stated in evidence, that we have no quantitative method for determining the actual amount of organic matter in muds. We have different methods, which have been from time to time developed and extensively used, by which we get results which give us indications of the relative degree of purity of a sample of water when examined by that particular method, there is no single method that gives us more than that. By taking the methods together, and considering the results which each individually furnishes, and the relations developed by the application of each individual method, we obtain something like a trustworthy indication as to the quality of the water by chemical examination, and nothing more.

16,238. And, having regard to the purpose for which it was employed, are you of opinion that Wanklyn's method is an appropriate one?—I am of opinion that for the general purposes of water examination Wanklyn's process furnishes a very useful result, that, in combination with the other method which we have used in connexion with it, it furnishes results upon which very great reliance can be placed, as indicating the purity of the samples taken from one and the same source.

16,239. (*Sir John Coode.*) And the two are the two best known to you and to science?—I think they are.

16,240. (*Mr. Norman Bazalgette.*) I will ask you another question upon Dr. Dupré's evidence; do you agree with Dr. Dupré as to the purification of the Thames water by the dissolved oxygen contained in it?—I do. I think the evidence with regard to the purifying action of oxygen is indisputable and complete.

16,241. (*Chairman.*) Do you mean the evidence that has been given before the Commission?—Yes, I mean the evidence which has been given before the Commission in connexion with the experimental examination of the water.

16,242. But you would have known that that would take place, would you not?—Yes, undoubtedly; there have been no new general results brought before the Commission. The fact that water continuously dissolves or absorbs oxygen from the air is an old and well established fact; the fact that water yields that oxygen to matters readily oxidisable dissolved in it is a well-known fact. The fact that that takes place proportionately to the rapidity with which the soluble matter is oxidised is also well known and well established. If we find, therefore, that water into which oxidisable matter is introduced shows a gradual diminution in the proportion of oxygen it contains we are sure that the rapid oxidation of the dissolved matter is proceeding. If we find that the amount of oxygen is reduced to a very small proportion, we are justified in concluding that the oxidation is proceeding almost as rapidly as the water can become re-aërated. If we find the proportion of oxygen in the water increases, we are justified in concluding that the oxidising power is gaining the mastery over the materials to be oxidised.

16,243. And you say the experiments here confirm your *a priori* opinion?—Yes.

16,244. (*Mr. Norman Bazalgette.*) I believe that there are materials of two classes which exist in suspension in a polluted river, which contribute to its power of self-purification?—Yes. I think it will be admitted on all sides that the matter which exists suspended in water deserves careful consideration in regard to its action upon a water contaminated by dissolved organic impurities. In the first place, there are certain mineral matters contained in suspension in river water which act upon certain classes of dissolved organic matter as precipitants, throwing them down in the form of insoluble materials, and, indeed, fixing them, so that they undergo very gradual change afterwards, and may be considered to be rendered practically permanent by this precipitation. Then there are also mineral matters which will have the effect of fixing any sulphur compounds which may be developed by the putrefactive decomposition of animal or vegetable matter containing sulphur, such as, for example, clays containing oxide or carbonate of iron. If by the putrefactive decomposition of the nitrogenous organic matter suspended in water sulphuretted hydrogen be evolved, those iron compounds will fix the sulphur from the sulphuretted hydrogen, and will act equally upon some other sulphur compounds, producing sulphide of iron, which sulphide of iron gives that black appearance to the mud, conveying to the uneducated mind a notion of filth and impurity which is erroneous, inasmuch as it is an indication of the purifying action of suspended matter which goes to form the mud itself.

16,245. Would the chemical action you speak of account for the black appearance of the mud depcsits of Erith which have been spoken of?—It would. I may state that one indication upon which the Commission can readily satisfy themselves by observation of this being the case is that, if that black mud be exposed to the air, it becomes brown in appearance. You can remove the brown surface, and you get a black colour underneath; but that gradually becomes brown again, consequent upon the decomposition of the iron sulphide in the mud by the action of the air.

16,246. (*Chairman.*) I have often noticed very black sewage coming from a place where one would not have supposed there was anything to make it black; for instance, from a kitchen sink; is that caused in the way you mention?—It is not at all impossible that it may be; in all probability, it may have been caused by a sulphide, either of lead or of iron; in both cases it would be black.

16,247. (*Sir John Coode.*) Sulphide of lead would be black as well as sulphide of iron, would it?—Yes.

16,248. (*Chairman.*) Does this black sulphide smell?—No, it has no smell.

16,249. But it has a black appearance?—It has a black appearance.

16,250. But does it get brown when it is exposed?—It is readily oxidised; the sulphur is readily separated, partially oxidised, and the iron is converted into brown oxide of iron.

16,251. (*Mr. Norman Bazalgette.*) I believe that on several occasions you have inspected the mud deposits of Erith, have you not?—I have.

16,252. What do you say as to the offensive smell we have heard of?—Upon the occasions of my visiting the causeway at Erith, which was in June and July last year, although I carefully searched for smell in the mud itself, I was not enabled to detect any. I found that there were many bubbles of gas collecting

*Sir F. Abel, C.B., F.R.S.*

20 June 1883.

upon the mud or collecting in the shallow puddles immediately over the mud, and by thrusting a pole into the mud gas was given off in considerable abundance. I smelt this gas, expecting to find sulphuretted hydrogen, but there was no trace of smell of any kind in this gas. I examined some of the gas bubbles upon the spot for sulphuretted hydrogen by the ordinary test, and failed to detect any. I collected some gas and took it with me to Woolwich and examined it, and I found it to consist chiefly of marsh gas; it was inflammable; it contained some carbonic acid and a small quantity of nitrogen, but not a trace of sulphuretted hydrogen. So that at any rate, upon the occasions of my inspections last summer, I was never enabled to detect the presence of sulphuretted hydrogen from the decomposition of this mud or from these mud deposits.

16,253. From your examination of the suspended matter, have you found any specimens of living animal and vegetable organisms in it?—I have stated that the suspended matter consists on the one side of mineral matter, and upon the other side it consists of animal and vegetable matters, and there is no difficulty in detecting living organisms in abundance microscopically in the fresh suspended matter in river water. The evidence which will be given to the Commission upon that by Dr. Sorbey, I have no doubt, will be quite conclusive. The action of these organisms would no doubt be a purifying one upon a water contaminated by dissolved organic matter.

16,254. (*Sir John Coode.*) Would the purifying influence be both from the animal and vegetable matter?—Yes.

16,255. (*Chairman.*) You are now referring to living organisms?—Yes, I am referring to living organisms which are nourished by the dissolved organic matter.

16,256. Capable of assimilating things to themselves?—Yes, capable of assimilating things to themselves and converting them into the ordinary products of burning or respiration. I may state that incidentally I obtained evidence of a certain amount of purifying action which, although I have not followed it far, I think may be worth mentioning to the Commission. In order to obtain conclusive evidence as to whether the Wanklyn process would be trustworthy when applied to samples of water which have been properly preserved in perfectly full bottles for several days after collection, I made a series of experiments. I collected samples of water off Woolwich Arsenal, and in each case one of the samples of water, the bottles being completely full, was set aside for a period of 14 days, while a portion of the other sample was examined by the albuminoid ammonia process immediately, or within 24 hours after collection; and it was found that the samples in the full bottles put away remained unchanged so far as the proportions of free ammonia and albuminoid ammonia were concerned which they contained. But of the sample of water which had been examined immediately, a portion was immediately filtered, through a special asbestos filter which had been heated to redness to deprive it of any possible impurity, and that was set aside in a bottle three parts full. Another portion of the original sample was also set aside in an unfiltered condition in a bottle three parts full. It was found that, allowing for a little loss of free ammonia which took place unavoidably during the filtering operation, there was but little diminution of free ammonia and no important alteration in the albuminoid ammonia in the filtered sample. But it was found, in the case of the unfiltered water which had been kept in a bottle partly full, that the free ammonia after 14 days in the perfectly closed bottle had disappeared, in one instance almost entirely, and in that two instances it had disappeared entirely. I conclude that this result was due to the action of the suspended matter contained in the unfiltered water. When that suspended matter had been removed by filtration, no such disappearance of ammonia took place.

16,257. (*Chairman.*) And applying that to the present case, inasmuch as there is suspended matter, how would it stand?—Inasmuch as there is suspended matter, in the presence of air, I consider that this suspended matter, quite apart from the effect of mineral matter which has been described, has a purifying action upon the organic impurities, or the products of decomposition of the organic matter contained in the water.

16,258. This is an additional purifying means then to the oxidation?—Yes.

16,259. (*Mr. Norman Bazalgette.*) The purifying action in these bottles being the twofold one that you have just described?—Yes; precipitation and the action of living organisms.

16,260. I believe you have inspected the river a good many times?—I have.

16,261. In what year did you inspect it?—I have inspected the river in 1878 two or three times, and again in 1880, 1881, and 1882, but more especially in 1882, and during the summer of that year.

16,262. First of all, will you tell us whether on many occasions you have been able to recognise the odour of sewage?—Except when I was actually in the sewage flow, I have only on one occasion, at a distance from the sewage, been able to recognise the distinct unmistakeable odour of sewage, and in that particular case there was a pretty steady and strong wind blowing towards me from the outfalls.

16,263. (*Sir John Coode.*) Where were you?—I was half way towards Erith from the outfalls.

16,264. That would be somewhere near Jenningtree Point?—Yes.

16,265. (*Dr. Stevenson.*) And how far would you have been from the nearest point of the outfalls?—Roughly, I should say, I would have been 1,000 or 1,200 yards from the outfalls.

16,266. (*Chairman.*) When you were "in the flow," what distance from the outfalls would you be then?—400 or 500 yards; and even there the odour was exceptional, when I was upon the river. The smell, undoubtedly, was there unmistakeably, but at a short distance, within from 50 to 100 yards. After that it becomes comparatively feeble, and you only get an occasional whiff of it, more especially when the water is stirred up by passing steamers, or by the screw on one's own steamer.

16,267. (*Sir John Coode.*) Does that answer refer to the northern or to the southern outfall?—It refers to both.

16,268. (*Mr. Norman Bazalgette.*) Upon that one occasion you have told us of, was a strong wind blowing in your direction from the outfalls?—There was.

16,269. (*Mr. Abernethy.*) Was that at high water or at low water?—It was just shortly after high water when the sewage was let out.

16,270. (*Mr. Norman Bazalgette.*) I believe it was your habit at one time, before the opening of the outfall, to travel by steamer from Westminster to Woolwich?—It was. I have been more or less intimately acquainted with the river for 35 years, and in the early days of my connexion with Woolwich I used to travel from Westminster to Woolwich by steamer. In those days, which were long before the sewage outfall days, the river was frequently in a very offensive condition, and the odour which I have of late years searched for in the neighbourhood of the outfalls, and very seldom met with, was a matter of by no means infrequent occurrence coming down the river as far as Woolwich.

16,271. For the last 28 years you have lived at Woolwich Arsenal, have you not?—I have.

16,272. Within what distance of the river?—Within 250 yards, and my place of work is 180 yards from the river.

16,273. Have you experienced any annoyance from the river?—I have not. I may state that a walk upon the river wall, or a breath of fresh air upon the T-pier at the Arsenal in the evening, has been very often my only chance of getting anything like recreation and fresh air; and I have never upon

any occasion experienced the least annoyance or inconvenience from the river at that point.

16,274. (*Sir John Coode.*) Do I rightly understand that your residence at Woolwich is 250 yards from the river?—Yes; and I have lived there the last 28 years, and my laboratory is within 180 yards of the river.

16,275. (*Mr. Norman Bazalgette.*) You have given us your own experience. Now, of course, there are many others continually employed at the Arsenal amongst whom you constantly move?—I am surrounded by a small number of houses occupied by official residents with whom I am more or less intimate; and I may state that we have had during these 28 years the usual visitations of sickness of one kind or another, but certainly in no one instance has there been any case of sickness which could be ascribed even remotely to the outfalls. I say this not simply from my own personal opinion, or as my own personal view, but that is the view of medical men living in the same place and attending upon the families.

16,276. Do the residents in the Arsenal suffer from no smells?—Yes; we are great sufferers from smells, not only in the Arsenal, but high up on Woolwich Common, the smells extending as far as Blackheath, all of which come from the large and increasing number of factories surrounding the outfalls and situated about the outfalls, and to a considerable extent up the river, as far as the Victoria Docks. I believe that there are as many as 14 manure works of one kind or other, large and small, and some of them of the most offensive description; and there are ten or a dozen chemical works, some of them very extensive. And this enumeration, I ought to say, does not include the very extensive gasworks at Beckton which favour us with smells occasionally.

16,277. I believe you dealt with these nuisances in a report in 1866, did you not?—I was called upon by the Secretary of State for War, in conjunction with an Army medical officer and the Royal Engineer officer in charge of the Arsenal, to examine into the complaints that were made at that time of emanations from those works which were growing up all round about the outfalls, which at that time had not been long established; and we, in fact, found that there was a substantial cause for the very great complaints which were made against those works in consequence of the development of noxious vapours by the careless manner in which the various operations connected with the conversion of refuse animal matter into manure, and other kindred operations, were carried out.

16,278. I believe you were a member of the Royal Commission on Noxious Vapours which sat in 1877?—I was.

16,279. Was there evidence laid before that Commission on account of the nuisance arising from the works in this neighbourhood?—There was a very large amount of evidence collected by the South-Eastern Sanitary Association and brought before the Commission with respect to the character of the odour arising from works at Deptford and down as far as Northfleet. Amongst the witnesses examined was Professor Heaton, who has given evidence here, and several well-known medical authorities; and I think the whole of the evidence was quite conclusive as to the very considerable extent to which the neighbourhood suffered from the emanation of noxious vapours from those factories. There was not one allusion, even a remote one, to the sewage outfall contributing in any degree, or the discharge of sewage into the river contributing in any degree, to nuisances that were suffered in the neighbourhood.

16,280. (*Sir John Coode.*) Did the South-Eastern Sanitary Association make any allegations against the sewage?—There was not a word said about it.

16,281. (*Mr. Norman Bazalgette.*) Originally I understand this case arose from the action taken by the South-Eastern Sanitary Association?—Yes.

16,282. But they did not complain of the sewage?—Not in the least.

16,283. Was no suggestion made that any of the nuisance proceeded from the outfalls at the time?—No. I have again carefully looked through the evidence, and there is not a syllable about it.

16,284. Having regard to the analysis, have you found that there has been of late years an increased pollution of the river?—I have carefully examined the analytical results which have been collected in the experiments made on both sides recently, and I fail to see any evidence of an increasing pollution of the river. On the contrary, I feel confident that it has been well established that the river is competent to deal with the amount of impurity discharged into it, and that the purifying power is at the present time in excess of the polluting influences.

Cross-examined by Mr. Lumley Smith.

16,285. One word with regard to this Commission on Noxious Vapours: that was a limited inquiry, was it not; that was to inquire into complaints which had been made of certain factories?—It was an inquiry into the grievances of particular districts in consequence of the emanation of noxious vapours.

16,286. From factories and chimneys and other things?—Or from any other source.

16,287. But "noxious vapour" was not interpreted to mean an accusation against the river?—But it spread very largely into an inquiry into the pollution of the streams.

16,288. Into the pollution of the streams from factories?—From factories.

16,289. But you do not suggest that upon that occasion the Commission went into the matter of the River Thames at all?—Certainly not.

16,290. It was not within the scope of their inquiry, I presume?—No.

16,291. Now, with regard to the progressive increase, you are speaking of the deduction you draw from the tables of analysis which have been put in here?—Yes.

16,292. When you speak about the progressive increase, as the population increases, necessarily the amount of sewage will increase, that must be so, must it not?—Certainly.

16,293. What is your view; you laid some stress upon the words that "at present" the purifying power was sufficient, I do not quite know what you meant by that?—I meant that as far as the examination had gone the purifying power was at present sufficient, and that, in fact, the purifying power was in excess of the polluting influences.

16,294. The time may come when the river will not be equal to the task that may be put upon it, but you consider at present it is equal?—I consider that, as far as one is enabled to draw a fair conclusion from facts, a very much greater degree of pollution may be satisfactorily dealt with, as far as the river is concerned, in the way in which it is dealt with now.

16,295. Do you consider the river never becomes offensive from the presence of sewage?—I would not say that.

16,296. You are not prepared to say that on certain occasions and at certain temperatures the river does not become offensive in consequence of the presence of sewage?—Within a particular and very limited area, it may be.

16,297. That probably has been within your own knowledge, have you never found the river offensive?—No, I have not; else I should have stated so. I have never had occasion even in the hottest summer in recent days to notice the smell from the river.

16,298. (*Chairman.*) Taking it from side to side of the river?—Only when I have been taking special observations right in the sewage stream.

16,299. (*Mr. Lumley Smith.*) There has been a good deal of evidence given that at certain times in

*Sir F. Abel, C.B., F.R.S.*

20 June 1883.

hot weather the river becomes very offensive from the sewage, are you prepared to doubt that that is so, or can you give any explanation why it should be the case?—I can only give you my own experience, and I can only tell you, though it is not strictly evidence, that my evidence would be confirmed by many who have lived in the arsenal.

16,300. You are judging by your own experience?—Yes, I am.

16,301. Now, with regard to Woolwich itself, is it not the fact that complaints have been made by residents as to the sewage?—Not of my own knowledge; I believe that upon several occasions complaints have been made of smells which not unnaturally have been ascribed to sewage, because they have been due to offensive odours somewhat like, though much more intolerable than, the odours evolved from sewage. I refer especially to the odours coming from the fish manure works, which are so disgusting that I trust the Commission may have the chance of experiencing them for a moment. I am not at all surprised that they have been ascribed to emanations from excreta; for I am convinced that in many instances, and certainly at Woolwich, smells of this description have been mistaken for smells emanating from the sewage outfalls.

16,302. However you agree with many of the witnesses that you can distinguish between the sewage outfalls and the factory smells?—The educated nose can; the popular nose, when it is in the neighbourhood of the sewage, would say, that is a sewage smell, when it smells any smell.

16,303. Yours, I presume, would be an educated nose?—To a certain extent it would be.

16,304. It does not want a person who is a scientific chemist to detect the difference between the smell of sewage and the smell of factories?—It wants a person who will give himself the trouble to observe and discriminate.

16,305. You do get rather accustomed to smells in the laboratory, I suppose?—I used to; but I am sorry to say that my official work takes me so much out of the laboratory that my nose has become sensitive again.

16,306. And you do not require to go now to your pier for your fresh air, you get your oxygen in other places?—Yes.

16,307. But the time when you used to go for your smell or whiff of fresh air, was that at a time when you were much engaged in the laboratory, and your nose was not sensitive?—I have still a lingering fondness for a seat upon the T-pier of the Arsenal.

16,308. Now, with regard to this smell at Jenningtree point, you smelt it when you were in the heart of the sewage?—Yes.

16,309. I presume that was on an occasion when you went down for the purpose of this inquiry?—Yes.

16,310. How many times have you been down for the purpose of testing the smell?—I have been down there seven times.

16,311. Was that going down in a small screw steamer, and then steaming away again?—No; going to Erith, and considerably beyond; to Northfleet, sometimes.

16,312. But on this occasion when you smelt the smell, what time of the year was it?—I believe that that occasion was on the 5th of August.

16,313. Did you make any memoranda as to the distances out at which you lost the smell upon those different dates?—I did not, because it was only a passing smell, a whiff as you would call it.

16,314. But if you took the steamer through the sewage, you must have got the sewage on each journey once?—I did.

16,315. But you have not made any memoranda as to the distance at which you lost it?—I have not.

16,316. Now, taking the water which was put unfiltered into a bottle, that water was put into a bottle three-fourths full?—It was.

16,317. Was it corked?—It was stoppered.

16,318. It was not filtered, and therefore there was certain suspended matter in it, not matter in solution, but suspended matter?—There was both matter in solution and suspended matter.

16,319. The matter in solution would be very much the same in either sample, would it not?—Yes.

16,320. But the matter in suspension would differ?—Yes, it would.

16,321. What is the process that takes place?—I will not attempt to speculate upon the precise action, but I imagine it might be due to animal or vegetable organisms existing in the suspended matter.

16,322. Do you mean alive or dead?—Alive.

16,323. Animals?—I would not presume to say whether they were animals or vegetables.

16,324. Which would produce sewage of their own, I presume?—That must be very minute, but still I presume they would have excreta.

16,325. Did you test the oxygen to see whether the free oxygen remained the same in that bottle?—I did not. I should say that in all probability it did not.

16,326. May it not be the fact that the ammonia may have been oxidised by the oxygen, and not by the suspended matter?—In that case it would have been equally oxidised in the filtered sample. In one case I removed the suspended matter, and in the other case the suspended matter remained. If the disappearance of the ammonia were due simply to the oxygen contained in the bottle, it would have been a matter of indifference whether the suspended matter were there or not.

16,327. But may it not be that the suspended matter acts as a sort of carrier of the oxygen, so as to bring it to work upon the ammonia?—I will not say it is not so, but still it acts upon the suspended matter, and I incline to believe that it is due to the action of the organisms acting on the suspended matter.

16,328. If it merely assisted the oxygen to act on the ammonia, the work would have to be done by the oxygen and not by the suspended matter?—The work would have to be done between the two.

16,329. What are those living organisms which you think devour the sewage; diatoms and bacteria?—That may be so, but I would not pretend to go into that matter.

16,330. This was a sample off Woolwich Arsenal, was it?—It was.

16,331. What time of the year was it taken; was it taken at a time when the suspended matter was large or small?—The samples were taken in August, September, and October.

16,332. Was that last year?—Yes.

16,333. Ammonia disappears very freely, does it not; in the mere pouring off of the water some of the ammonia disappears?—Yes, but this is quite a different thing. In the case of the unfiltered water, which was in a perfectly closed bottle, the ammonia did not disappear at all or only to a very slight extent; so there was no error of experiment to account for the disappearance of ammonia. A certain amount of ammonia disappeared from the filtered samples, which was due to the fact that the water was exposed for a certain amount of time during filtration, but the extent of disappearance was small compared to the total disappearance, when the suspended matter was present.

16,334. Is it your view again that the blackness of the mud is entirely due to the sulphide of iron?—I will not go so far as to say that it is entirely due to that, because I believe it would be difficult to prove that it is entirely due to that: but I believe it is chiefly due to that.

16,335. Where does the iron come from?—From the suspended matter contained in the water, from the saltings which are washed into the water.

16,336. The sewage itself is black, is it not?—I was not aware of that.

16,337. His Lordship put the case of sewage coming out of a sink being black, and for myself, I thought it was generally black?—I think, when you

come to examine it properly, you will not find it black; it is dark-coloured undoubtedly, but it is certainly not black.

16,338. I was going to ask you where the blackness of sewage came from, but you do not agree that it is black?—I cannot agree that it is black.

16,339. Where does the iron come from that discolours it, as you say?—From the mineral suspended matters which are continually washed about in the river and deposited on the saltings.

16,340. Then the saltings themselves ought to be black. If the iron from them turns the other mud black, why does not it turn the mud upon the saltings black?—So it would if they were exposed long enough.

16,341. But they are exposed for a great part of the tide and during the year, so why are they not black?—Because they have not the opportunity of being subjected to this process of being mixed up in a finely divided state with the sewage in the water and thereby undergoing change as the sewage mud does.

16,342. Now as to the iron, I suppose that comes from the road detritus. Every wheel that goes round, I suppose, leaves a certain amount of iron upon the roads?—And from the horse shoes; there is no difficulty in finding iron in the detritus.

16,343. May it not be that this blackness that you see upon the mud at the banks at Erith and elsewhere is coming from the blackness of the sewage?—Certainly not.

16,344. (*Chairman.*) Do you say that none of it has so come?—I do not say none of it, but that that amount of jet-black appearance cannot have been produced in that way.

16,345. (*Mr. Lumley Smith.*) A great deal of the iron you found in the mud would have come largely from the iron of the wheels which is worn away upon the roads?—Yes, no doubt it would come down through the sewers.

16,346. That goes through the sewers and is deposited upon the banks in the neighbourhood of Erith and elsewhere?—Yes.

16,347. Why does not it blacken the saltings from which it is taken?—It does to a certain extent.

(*Chairman.*) Supposing this were iron brought down by the sewers, what harm does it do?

(*Mr. Lumley Smith.*) It shows that it is sewage mud which is there; the iron itself would do no harm.

16,348. (*Chairman.*) Is there more of this black covering near the outfalls than there is lower down or higher up?—The largest amount I have seen of it is in the neighbourhood of Erith; it has varied a good deal. Some years ago, between Erith and the outfalls, there used to be a much greater deposit of that particular kind of mud than there is now.

16,349. Do you find it all along the river?—I would not speak to the river generally, but I know it has existed there, because I have used the mud deposits for experimental purposes.

16,350. (*Sir John Coode.*) You would say that the blackness is not a measure of the offensiveness of the mud?—Not in the least degree.

16,351. (*Dr. Stevenson.*) What is the colour of the mud, do you know, in the other parts of the Thames?—A brown colour generally; it is sometimes of a black tinge, but it is generally brown.

16,352. (*Prof. Williamson.*) I understand you to express the opinion that the black colour is the result of two things, partly the sulphur and other organic substances in the sewage, and partly the iron which comes from the roads through the sewage, and partly from the suspended clay which comes down the river?—That is so.

16,353. It is not the sewage itself, but a product of the sewage?—The result of sewage entering the river.

Cross-examined by Mr. Beaumont Morice.

16,354. You mentioned something about the gas bubbles, have you noticed that feature on many occasions?—I have noticed it on every occasion, whenever I have been to the mud in the neighbourhood of Erith; it varies considerably in quantity.

16,355. Did you notice any sewage smell at the places where you noticed these bubbles?—No, I did not notice any sewage smell.

16,356. Have you taken any or many analyses at the parts where those bubbles occurred?—I merely collected the gas from those bubbles.

16,357. Did you do that upon more than one occasion?—Yes, upon more than one occasion.

Examined by the Commission.

16,358. (*Chairman.*) I suppose you have heard about fish being suffocated or poisoned or put an end to as low down as Gravesend?—Yes.

16,359. I suppose you attribute that to the effect of the sewage?—I do.

16,360. The sewage is sensible there, if I may say so, it is not so destroyed or mixed up that you could say it is no longer sewage, I suppose?—There is no doubt there must be sewage there, but I cannot say that I consider the disappearance of the fish from that part can legitimately, by a process of exhaustive reasoning, be ascribed to the action of the sewage direct; when I speak of its disappearance being due to sewage, I mean in this way that the oxygen of the river is so constantly actively employed in oxidising the sewage matter that is sent into the river that there is not sufficient oxygen there to support the life of fish.

16,361. Now tell me this, although I think I can guess the answer, but we have heard that some matters putrify, and others get oxidised. I understand the same thing might either putrify or be oxidised?—There is no exact line to be drawn between the occurrence of the two charges; putrefaction is accompanied by oxidation; you can draw no line at which you can say that a material simply putrifies and does not oxidise, the oxidation proceeds concurrently with the putrefaction.

16,362. Is this anything like a reasonable guess on my part, that oxidation would take place instead of putrefaction if the oxygen could get to each of the particles with great facility, whereas, if it cannot, putrefaction would take place?—It can hardly be that, because it depends very much upon the conditions as regards temperature and exposure to the air which surround the question, but there are certain animal substances which are much more liable to putrify than others, and some which would more readily oxidise if they were exposed to conditions favourable to oxidation.

16,363. Why should not there be putrefaction in mud, as I understand Dr. Tidy says is the case. Could you tell *à priori* that it would not putrefy, and if so, why?—I could not say. In fact, I should say that, given putrescible animal matter in mud, and expose that to the necessary temperature such as a summer heat, it must of necessity putrify, but oxidation will be going on at the same time.

16,364. Is your answer to this effect that the matters brought down by the sewage, which may be more or less deposited upon the mud, are more likely to be oxidised than to putrify?—That would entirely depend upon the conditions to which they were exposed. If the animal matter were upon the surface, as in the case of mud upon the river's bank, and were exposed to the heat of the sun, the tendency would be

*Sir F. Abel, C.B., F.R.S.*

20 June 1883.

to putrefaction in the first instance. If the matter were mixed up and associated with the oxygen dissolved in water, there is no doubt putrefaction might commence, but the oxidation would commence so rapidly that you cannot draw a line between them.

(*Dr. Tidy.*) There is no doubt about that being the case.

16,365. (*Dr. de Chaumont to the witness.*) From your experiments upon the ammonia in the water, did you ascertain by analysis what became of the nitrogen?—I was unable to carry the experiments so far, but I have no doubt we have an increase of nitrogen oxides; there might also be an assimilation of nitrogen by the animal and vegetable organisms. My object was to ascertain whether one might rely upon getting trustworthy results in the examination of samples of water when we were compelled to preserve them for some considerable time after their collection, and I found that one could, and incidentally I made these observations with respect to the effect of the suspended matter upon ammonia.

The witness withdrew.

Dr. Augustus Voelcker, F.R.S., called in; examined by Mr. Norman Bazalgette.

*Dr. A. Voelcker, F.R.S.*

16,366. You are a Fellow of the Royal Society, Consulting Chemist to the Royal Agricultural Society of England, and were formerly Professor of Chemistry in the Royal Agricultural College, Cirencester?—Yes.

16,367. I will not take you through your experience, as probably the Commission will take that for granted, First of all, to clear up one point, I will ask you this question: were you with Mr. Dibdin when he saw the slaughterhouse refuse, as to which he spoke, lying upon Erith foreshore?—Yes, that was last Saturday.

16,368. Will you tell me what your impression was of that?—All I can say is that there was an abominable nuisance arising from the refuse of the slaughter-houses. The smell was most disgusting. We counted no less than 14 sewers, or sewage pipes, that discharged their contents upon the foreshore. There were also entrails, bits of skin, and similar animal matters all scattered about the shore.

16,369. Was what you saw at Erith sufficient, in your judgment, to account for the complaints of nuisance from the people who work in the mud and along the foreshore there?—Yes, quite so. The fact is, it was such an abomination that Sir Frederick Bramwell, who walked with us, would not venture to go very far. He backed out of it as soon as he could.

16,370. In the months of June, July, and August 1882, I believe you made several inspections of the river with Dr. Dupré and Mr. Dibdin?—Yes, from Westminster to Purfleet.

16,371. And you returned, I believe, over the same range of river?—Yes.

16,372. What did you do upon most of those visits?—We took note of the neighbourhood and the condition of the river, more especially to ascertain if there were any bad smells arising either from sewage discharge or other sources.

16,373. Speaking generally, first of all, what did you find. Did you find that there were bad smells arising from the river?—No; except direct in the sewage stream, the river water does not give off any disagreeable smell. Of course, when you are in the stream of the sewage, the smell, as you might naturally imagine, is bad, but it gradually disappears, and at a distance of about 600 or 700 yards, according to the state of the wind, and whether the air is calm or windy, the sewage smell entirely disappears, and even when the water is shaken up and sniffed at, you get only the faint smell which is perceptible all along the river (perhaps gradually increasing as you go under London Bridge, where it is sometimes a little more perceptible), but all along from Westminster through the bridges to Erith you have this peculiar mawkish smell, reminding you of half-dried linen, or something of that sort.

16,374. So much for the river. Did you find that the factories were equally innocuous as regards smells?—The factories discharge a very large quantity of a most penetrating, disagreeable smelling, vapour. There are a great many factories all along the river, and I know what is produced in them. Taking the nearest point at Cubitt Town, you will have there the extensive artificial manure works of the London Manure Company, where something like from 40,000 to 50,000 tons of artificial manure, such as blood manure, dissolved bones, artificial guanos, and a variety of compound manures, are manufactured. The smell which is produced upon the addition of sulphuric acid to some of the refuse material, such as blood, or fish, is most obnoxious and penetrating. It is not due, I need hardly say, to any ammoniacal emanations, but to the volatile fatty acids, propionic, phocenic, and similar volatile fatty acids. The odours will travel a long distance, and are perceptible, to those who are accustomed to that kind of smells, to perhaps three quarters of a mile up and down the river, when the wind blows in the proper direction.

16,375. May we take it that upon these several occasions when you went down the river you did not smell the river, but you did smell the factories?—Distinctly.

16,376. What considerations do you think would guide you to a judgment of the comparative degree of the purity of a tidal river into which impurity is discharged?—I would be guided by the character of the suspended matter, that is to say, whether the suspended matter was more of a mineral nature, or of a combustible nature. The more organic or combustible matter is mixed up with the suspended matter, the more offensive it is, speaking generally. Then the next question is the degree of aëration, the more oxygen there is present in the water, the more it approaches the point of complete saturation with oxygen, the better, other circumstances being equal, the water would be. Then, in the third place, I would look upon the amount of oxygen which is readily consumed as indicating the comparative degree of putrescibility, that is to say, if matters are present in water which are readily oxidised and consume a good deal of oxygen, that water will be a bad one. If, on the other hand, not much oxygen is consumed, we may fairly conclude that putrescible matter is present in but small or, it may be, insignificant proportions.

16,377. Have you applied these considerations to the Thames below the outfalls?—Yes, by following out the method we have adopted in our inquiry, that is to say, by taking account of the suspended matter—of the character of the suspended matter—the amount of oxygen consumed, and the amount of albuminoid ammonia found.

16,378. Will you state shortly the conclusion at which you have arrived with regard to each of those considerations, and then the general conclusion at which you have arrived?—The general conclusion is that which has been already stated by Dr. Dupré.

(*Chairman.*) With a witness of such eminence as Dr. Voelcker, one is extremely unwilling to cut him short; but if he has nothing to say except that he agrees in what has been already said, you might put that to him and ask him, is there anything you would like to say in addition?

(*Witness.*) I should like to say that I have found in the most polluted Thames water nitrates present. We have not included those in our report, in order not to make it more complicated than it is already at present, and not to introduce details which might have

a confusing effect; but I may say that I have invariably found in Thames water nitrates present; they evidently arise from the oxidation of nitrogenous matter, showing the readiness with which animal matters are converted into nitric acid even in the presence of suspended matters which one would imagine to have a reducing effect: but, notwithstanding the presence of suspended organic matter, I have invariably found nitrates in Thames water polluted with sewage. In the sewage in the reservoir itself I find no nitrates. Here you have free and albuminoid ammonia, and no nitrates, evidently because there is not sufficient oxygen present to produce the nitrates; but even within a short distance, say 1,000 yards of the outfalls, or in any part of the river, you will find invariably nitrates present. This clearly shows that there is an over-abundance of available oxygen present to destroy, I should say, not the whole of the organic matter, because I do not know what the whole of the organic matter is, but the most obnoxious part, the most putrescible kind of organic matter; and so far it is very comforting to know that at no time of the year, and under no circumstances, was there a lack of available oxygen to burn up, so to speak, the most objectionable organic matter, and so as not to create anything but a mere local nuisance. That there is a local nuisance one cannot deny; you cannot discharge a large body of sewage from an outfall without creating a local nuisance, but it is remarkable how quickly this peculiar sewage smell is destroyed, and I am perfectly certain in my own mind that people who have not educated noses, or experience with regard to these smells which are given off from the factories on the banks of the Thames, and I may say I am intimately acquainted with most of them, and can discriminate by the smell one factory from the other,—I say I am sure that most people who are not acquainted with these facts mistake certain animal emanations, such as come from the fish manure works, especially in a dilute condition, for sewage. It is that peculiar animal nasty smell which often is more like that of sewage in a highly diluted state at a long distance from the factory than in the immediate neighbourhood.

16,379. (*Mr. Norman Bazalgette.*) When you speak of a local nuisance, within what limit would you localise the nuisance?—I should say, not more than 1,000 yards, if so much.

*Dr. A. Voelcker, F.R.S.*

20 June 1883.

16,380. Upon each side or on one side?—From the outfalls downwards.

16,381. Do you agree with Dr. Dupré and Sir Frederick Abel that the dissolved oxygen to be found in the Thames water is more than sufficient to oxidise the polluted matter which is poured into it?—Certainly.

16,382. Do you agree with those gentlemen whose names I have mentioned that Wanklyn's method is the right method to employ for the purpose for which it has been employed?—Yes, for giving comparative results.

(*Mr. Norman Bazalgette.*) Now, my Lord, Dr. Voelcker has made a special inspection of all the nuisance factories between the outfalls and Erith, and I would like to put questions with respect to them shortly to him.

(*Chairman.*) I think that would be important.

(*Witness.*) Eliminating those which do not create a nuisance, and only mentioning those which do produce a nuisance, the first, which I have already alluded to, is the London Manure Company's works, at which they produce from 40,000 to 50,000 tons a year. Then we come to the considerable works of W. R. Goold and Company, artificial manure manufacturers, which are in close proximity to Messrs. Pursers of the London Manure Company's works. Approaching the Victoria Dock, the smell upon the river becomes very offensive, and remains so for a considerable distance from the following works: Messrs. James Gibbs and Company, artificial manure works, dissolved guano, blood manure, and the like; they must make something like 60,000 tons a year, I should say. Then Odam's Nitro-phosphate Blood Manure Company almost joins the works of Messrs. Gibbs. They probably make per annum more than 60,000 tons of artificial manure. Next door to Messrs. Odam's works we come to Messrs. Thomas Farmer and Company's artificial manure works, where a good many thousand tons of artificial manures are manufactured in a year; and then there are still more extensive works, standing on about 2½ acres of ground, belonging to Messrs. Ohlendorff and Company.

Adjourned to Tuesday next at half-past 12 o'clock.

---

# FORTY-THIRD DAY.

## Tuesday, 26th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.

FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

DR. AUGUSTUS VŒLCKER F.R.S. called again; further examined by MR. NORMAN BAZALGETTE.

16,383. When we broke off on the last occasion, you were giving the results of a special inspection which you had made of the various manufactories upon the banks of the Thames, which in your judgment would continue the nuisance—would you go on where you broke off?—I think the last works I alluded to were Messrs. Ohlendorff's dissolved guano works, which are very extensive works for the manufacture of dissolved guano; they have also large stores of Peruvian guano, and manufacture dissolved bones and similar refuse manures.

26 June 1883.

16,384. (*Chairman.*) Where are they?—At the Victoria Docks Tidal Basin. There is a group of artificial manure works beginning with Messrs. Gibbs's, followed by Messrs. Odam's Nitro-phosphate or Blood Manure Company's Works. Next come the works of Messrs. Thomas Farmer and Company, and the last of that group, which as I have stated are all close together, are Messrs. Ohlendorff and Company's Peruvian guano works. Then a little further down at Silvertown are the soap works of Messrs. Knight and Sons.

*Dr. A. Voelcker, F.R.S.*

26 June 1883.

16,385. Their works might be smelt in Woolwich Reach, but I do not suppose any of those works would be smelt as low down as Barking Creek, would they?—That depends a good deal upon the direction of the wind and whether the manufacture is carried on well, or in a careless manner. At the present time the smell cannot perhaps be very considerable, because the manufacturing season has just ceased. After the turnips are sown, practically but little dissolved guano or other artificial manures are sold, and the nuisance at the present time would not be so great as in the spring when there is a considerable pressure of business.

16,386. Would that ever be smelt at Barking Creek?—At Barking Creek there are other works which smell.

16,387. But would those ever be smelt at Barking Creek?—I should hardly think they would be smelt so far; 3 miles is a considerable distance, but all along from there down to Barking Creek, there is a succession of smells which sometimes are stronger than the sewage, and then you get another kind of oily smell.

16,388. (*Mr. Norman Bazalgette.*) Then I think you come to Messrs. Simpson and Company's Petroleum Stores?—I do not think there is very much smell coming from these stores, but still there is the prevailing oily smell, which is perceptible wherever large numbers of petroleum casks are stored.

16,389. Will you continue your statement, simply calling attention to those works from which you think a special nuisance arises?—Then we come to the ammonia works and the tar works of Messrs. Bird, Bolton, and Hayward. Like all tar works there works spread a strong smell, and when sulphate of ammonia is made, sulphuretted hydrogen unfrequently is given off.

16,390. (*Mr. Michael.*) And that is not a very pleasant smell?—No; at times it is very strong. The last time we went down the river, last Saturday week, the smell of sulphuretted hydrogen coming from the Beckton Gasworks was very powerful.

16,391. That was from the sulphate of ammonia works there, was it not?—Yes; that was from the sulphate of ammonia works.

16,392. (*Mr. Norman Bazalgette.*) I think we will deal with the Beckton Gasworks as we go along—perhaps you had better follow your list in order?—Then we come to the chemical works of Messrs. Spencer Chapman, and the chemical manure works of Mr. Mark Finch, and those are succeeded by the Silvertown India Rubber and Gutta Percha works. I do not know that the last-mentioned give off very much smell. Then follow Messrs. Petty and Cairns' oil mills; there is that pervading oily smell which hangs about all oil mills. Then we come to the extensive Beckton gasworks, where large quantities of sulphate of ammonia are manufactured, perhaps something like 30,000 tons in the course of the year; they are the most extensive sulphate of ammonia works in the Kingdom.

16,393. Could 30,000 tons of sulphate of ammonia be manufactured without a considerable amount of sulphuretted hydrogen being evolved?—Yes, it could, if great care were taken either to absorb or to burn off the sulphuretted hydrogen.

16,394. But do they as a matter of fact?—When a manufacturer is hard pressed, and a large order has to be executed in a given time, the operations are unduly pushed on, and, as a matter of fact, sulphuretted hydrogen is allowed to escape in sulphate of ammonia works, and we had a practical proof of this the last time we went down the river when sulphuretted hydrogen in considerable quantities was being given off from the Beckton gasworks.

16,395. In addition to the sulphate of ammonia, is there also a good deal of gas lime produced?—Yes; there is a good deal of gas lime produced which is an unsaleable commodity in that locality; people do not know what to do with it. However useful gas lime may be in a district where there is no lime in the soil, it is a drug there. Even the ordinary refuse lime from the soapworks which is produced at Silvertown has to be carried out to sea.

16,396. Is gas lime a fragrant product?—It is a very disagreeable smelling product indeed. It has a very persistent smell; it smells of sulphuretted hydrogen and gas and tarry matters, but it is mainly the sulphuretted hydrogen which is given off on the exposure of the gas lime to the air which creates the nuisance; and there must be very considerable quantities of gas lime produced at the Beckton gasworks. That gas lime has to be carried away in barges which do not spread a very nice flavour as they go along the river.

16,397. Now will you pass on to the next manufactory?—The next manufactory is the works of Messrs. Lawes, which occupy several acres of ground with sulphuric acid works and artificial manure works. Messrs. Lawes' works manufacture certainly not less than 50,000 or 60,000 tons of various manures, such as blood manure, dissolved guano, super phosphate of lime, and similar manures. Then a little lower down the river, not very far from Messrs. Lawes' works are some very bad smelling stores and works, the guano stores of Mr. Daniel DePass, who imports guano from Patagonia, which is more powerful in its smell than the Peruvian guano, being wetter and a fresher product than the Peruvian guano, which we now obtain from the south of Peru.

(*Chairman.*) I suppose we might almost take it for granted that the reason these works are all there is, that they might be out of the way of those people who would complain of them, and that, therefore they are in a very reasonable position.

(*Mr. Beaumont Morice.*) This matter is not contested; we do not say but what there are plenty of these manufactories down the river.

(*Witness.*) I noticed a peculiar fish smell from works lower down the river, and nearer Erith which belong to a Mr. Laing, who works up the fish refuse from Billingsgate, and makes it into a dry fish guano; perhaps that is the greatest offender next to some fish manure works upon the opposite side of the river belonging to Mr. Johnson. Johnson's fish manure works we could distinctly smell the last time we went down the river, and also upon previous occasions; they are the fish works which produce the greatest nuisance. The smell of fish manure travels such a long distance and is very persistent in its character, it is not easily destroyed; you cannot oxidise as you can perishable substances. Decomposing flesh is more readily destroyed, but from these fish works you get volatile fatty acids which travel a long way; they are very persistent.

16,398. (*Mr. Norman Bazalgette.*) Can you tell us from your personal experience whether the smell from these fish works is perceptible at Erith?—Certainly; upon several occasions we have smelt it. When the wind is in that direction it is constantly smelt.

19,399. We have not got half way down the list, but I will not continue the detail of this part of the case any further.

(*Chairman.*) If you were to say that within a certain space there are so many manufactories, would not that be sufficient?

(*Mr. Norman Bazalgette.*) The reason I was giving this evidence was that your Lordship was pleased to say upon the last occasion that this evidence was important.

(*Chairman.*) I do not recollect saying that, but I have no doubt I said it from the fact that several witnesses had said that they had smelt smells, and that those smells could be shown to proceed from manufactories down the river.

Cross-examined by Mr. Beaumont Morice.

16,400. Do not the factories that you have mentioned lie between Woolwich and the Crossness outfall mostly?—A good many do.

16,401. And many more close to the Crossness outfall?—No doubt.

16,402. Were you able to discern the difference between those smells and the sewage smell?—Yes.

16,403. Do you say that the sewage in the reservoirs is at all altered before it gets into the river; is it at all purified upon the way down the sewers?—No.

16,404. Not at all?—I do not say that it is not at all purified, but it is a liquid which is in constant change, as soon as it is discharged it gets away.

16,405. But what I want to know is, does any purification take place of the sewage by the time it gets into the reservoirs?—I am hardly prepared to say whether it does not smell stronger or less so.

16,406. Let me draw your attention to the evidence you gave upon the Essex Reclamation Bill. You were asked, "Do you think the sewage would be just as "good 40 miles from town as it would be 5 miles "from town," to which you replied "I think so"; do you agree to that?—Yes, that meant for agricultural purposes.

16,407. That it remains for all practical purposes in the same condition, as sewage?—No, it gets purified; it may become almost inocuous, so as not to create any nuisance upon being applied to the land.

16,408. (*Sir John Coode.*) And might not that very well be so without the fertilizing properties being diminished?—Yes; in fact, as I contend, the inodorous and clarified sewage is the better for irrigating purposes; if you could filter it, it would be better.

16,409. Why so?—Because the suspended matter produces upon the surface of the soil a mechanical obstruction; it closes up the pores.

16,410. Do you mean to convey to the Commission that it is more finely divided and therefore in a better condition for distribution over the land; is that what you wish to convey to us?—The most valuable fertilizing matters occur in sewage in perfect solution, whereas the suspended matters are comparatively of little value, and when they are deposited upon the surface they form a crust which is injurious to the vigorous growth of plants, and which neutralizes, to a certain extent, the fertilizing properties of the soluble matter in the sewage. At 40 miles sewage is as good as at five for agricultural purposes, if not better.

16,411. (*Mr. Beaumont Morice.*) Did I understand you to say that you found no nitrates present in the reservoir?—That is so; not in the reservoir.

16,412. May I take it from you that there has been no purifying action upon the sewage up to that period?—I do not think it will have much purifying action except the mechanical deposition of any suspended matter.

16,413. Now I will draw your attention to another point; you would not advice sewage being dealt with or used in proximity to any towns or inhabited places, would you?—Certainly not, unless there are very perfect precautions taken to remove the suspended matter which causes all the nuisance.

16,414. You have mentioned the refuse lime from these gasworks; do you know what is done with the refuse lime from the gasworks at Beckton?—I take it, that it is carried out to sea.

16,415. But you do not know positively?—I do not know that with regard to the gasworks, but I know it with regard to Messrs. Knight's works.

16,416. (*Chairman.*) I understand you to say it must be got rid of at any rate?—Yes, it must be got rid of; there is no sale for it. I know with regard to Messrs. Knight's soap works that they carry it out to sea.

16,417. (*Mr. Beaumont Morice.*) You do not say that it goes into the river?—I do not.

16,418. You have mentioned the particular fish smell that you smelt; have you often been at Erith and smelt that smell there?—Yes, perhaps I have been at Erith half a dozen times, at various times in one year. During this inquiry I was altogether eight times at Erith, and upon two occasions which I distinctly remember, I have smelt it.

16,419. Have you smelt other smells at the same time?—At Erith?

16,420. Yes?—I was so impressed with the fish smell that I did not trouble myself about the other smells.

16,421. That was above everything else, was it?—Yes, it killed all the other smells.

16,422. Now, only one more question—you stated that the sewage may be a local nuisance?—Yes, it may be.

16,423. Have you ever followed and seen how far you could trace the sewage from the outfall?—Do you mean visibly or by the smell?

16,424. I mean by the swell?—By the smell I should say not above 600 yards, if so much.

16,425. Have you followed it down?—Yes, at about 1,000 yards it loses its colour and is lost in the general stream.

16,426. What time of the year was it that you did that?—In the months of July and August last year.

16,427. Do you remember what the weather was at the time?—The weather was rather cool, it was a very cold summer last year, at least the summer months were cold.

16,428. I think you were with Mr. Dibdin when you mentioned about the slaughterhouse at Erith, were you not?—Yes, I was with him. Mr. Dibdin, Dr. Dupré and myself and Sir Frederick Bramwell, went down a part of the way, but Sir Frederick did not venture far.

16,429. I should like you to tell the Commission exactly what you saw, was it anything more, I mean, than some blood trickling down from a butcher's shop?—Yes, certainly; it was so bad that it was dangerous to walk about for fear you would tread in some horrible mess; we counted 14 drains of smaller or larger dimensions.

16,430. What time of the tide was this?—It was low tide. Then the beach was strewn about with entralls and refuse of animals.

16,431. Did you notice any sewage smell there as well?—No, I cannot say I did.

16,432. Did you notice any sewage mud?—Yes.

16,433. You did?—Yes, I did, and I tried to smell it, but I could not, it did not smell.

Re-examined by Mr. Michael.

16,434. What is about the distance, when sewage farms are established in the neighbourhood of towns, that they are taken from inhabited dwellings, what is your limit?—I do not know that I should feel inclined to prescribe any limit.

16,435. (*Sir John Coode.*) What is the nearest you know to a town?—The sewage farm at Bedford is close to the town.

16,436. (*Mr. Michael.*) With paths running through frequented very much by the inhabitants?—Yes.

16,437. And conducted without any nuisance whatever?—Yes.

The witness withdrew.

DR. WILLIAM ODLING, F.R.S., called in and examined by MR. MICHAEL.

*Dr. W. Odling, F.R.S.*

26 June 1883.

16,438. You are a Fellow of the Royal Society, a Fellow of the Royal College of Physicians, and Professor of Chemistry in the University of Oxford?—I am.

16,439. I think you have been acquainted with the river Thames for the last 25 years?—I have.

16,440. And you have been very largely engaged in investigations as to its character?—Yes; I was engaged largely in such investigations in the years 1857 and 1858 in conjunction with Dr. Dupré, and in conjunction with Dr. Barnes at the same time, who was then medical officer of the "Dreadnought" hospital. I was also engaged in 1868 and 1869 in conjunction with the late Dr. Allen Miller, and I have been engaged in 1881 and 1882 in relation to this inquiry.

16,441. You have heard the evidence given by Dr. Dupré and Sir Frederick Abel, have you not?—Yes, and I entirely concur with what they have said.

16,442. What do you say with respect to the self purifying power of the river?—I say in particular, that I quite agree with what Professor Abel has said, that the self purifying power of the river is in excess of the polluting action of the sewage discharged into it; so that even the worst stretch of river water oscillating above and below the outfalls, does not get so polluted as to be a nuisance.

16,443. How do you consider that fact has been established?—I consider that fact to have been established both by ordinary observation of the river; that as a body of water, it does not smell offensively or look offensively, that there is no evidence to the senses that it is polluted; and secondly, that when we come to examine it by analytical methods, we find that there is no definite body of polluted water which can be distinguished from the general mass of river water, but that starting from Teddington, there is a continuous gradual increase of pollution till you get to the outfalls, and then a gradual decrease of pollution till you get to Southend, when the water, *qua* organic matter, is in exactly the same position as it was at Teddington. The increase and decrease is perfectly continuous, it forms a curve if you take the average of a number of observations. Taking the average of three hot months, July, August, and September 1882, the condition of the water at Erith is such as might result from adding one portion of average sewage, to 27 parts of Teddington water, and at Purfleet such as would be produced by adding one part of average sewage to 49 parts of Teddington water. In other words, the sewage would form a 28th in one place, that is at Erith, and at Purfleet it would produce about one 50th, that is to say, two per cent.

16,444. Now I will ask your opinion shortly as to the chemical processes which have been practised with a view of ascertaining the condition of the river water.

(*Chairman.*) If that is so which you have stated, it must be attributable to the purifying power of the water, because there is no addition of water at all between the two places.

(*Mr. Michael.*) I will come to that in a moment, and the witness will explain how the purification is produced, and the means required for the production of it

(*Witness.*) It has been made a sort of reproach to us that we have not used the combustion process. I would say I have not used the combustion process in this case for the same sort of reason that I should not think of taking a razor to carve a leg of mutton, because the coarser method is better adapted for the purpose, that is to say, the Wanklyn and the permanganate processes. It is not so much a matter of chemistry, as a matter of common sense. If you examine Teddington water by any process you like, and then examine sea water by the same process, and you find they each give you a result which you can call 1, and if you examine sewage by the same process and you find it gives you 28, and if you find a continuous increase up to the outfalls, and after that a continuous decrease, and if you get the same general average result by three independent modes of examination, it is evidence, and cumulative evidence, to show that you have the measure of pollution and purification.

16,445. (*Mr. Michael.*) Even if you adopt the razor for chopping the block, does it do more than tell you the proportion of organic carbon and organic nitrogen which was present in a given sample of water; but does it do more in telling you what the source of that organic carbon and organic nitrogen is than the other processes do?—No, it does not. You may take any process you like; practically if you take the tables handed in by Dr. Tidy, you find that his results as given in his second table show substantially the same thing. He finds that taking the stretch of water from Teddington to Battersea, the organic carbon is ·2, from Vauxhall Bridge to Deptford it is ·3, from Greenwich to the Albert Dock it is ·6, from Beckton to Crossness it is ·7, and from Erith to Purfleet it is also ·7, with rather a smaller hundreth—and beyond that he does not go; but we do, and we see that thence to Southend there is a gradual decrease in the curve. Now I should be glad if the Committee will allow me to call attention to the results brought out by Dr. Frankland. Between October the 28th and November the 11th, there are 40 analyses put in of water examined at Saint Paul's Pier, and upon the same 14 days there are 40 analyses put in of the water at Erith. Now you may examine the whole set, and compare the first ten with the first ten or the last ten with the last ten, or the whole 40 with the other 40, and there is always an excess of organic carbon at Saint Paul's Pier as compared with what there is at Erith. Then Dr. Frankland is asked in his examination with regard to this, and he says the water at Saint Paul's Pier at that time contained no appreciable trace of sewage; from which it would follow, if we are to depend upon these analyses, that there must have been a minus quantity of sewage at Erith. Now the mean of the 40 results, at Saint Paul's Pier, upon the days between October the 28th and November the 11th, is ·503, and the mean of the 40 results obtained at the same time at Erith is ·400 of organic carbon in 100,000 parts of water.

16,446. (*Chairman.*) You say it shows that if there is nothing at Saint Paul's wharf, there is less than nothing at Erith?—Yes, that is the deduction to be drawn from the figures and statement I have just quoted.

16,447. This must be susceptible of some explanation, because of course it cannot be so—do you impeach his accuracy as to Saint Paul's wharf?—I impeach the accuracy of the interpretation, because I say there must have been sewage, or something in the nature of sewage at Saint Paul's wharf.

16,448. What is the meaning of that decimal figure?—It means carbon, which is the most marked ingredient of organic matter. If you estimate the organic carbon, you get an approximation to the amount of organic matter; I may say that the organic carbon in Teddington water is ·25, and at Saint Paul's Pier it is double; nevertheless there is the remarkable fact, that during these 14 days in which the river was in flood, there was absolutely a less amount of organic carbon at Erith, than there was at Saint Paul's Pier.

16,449. It is impossible that there may be something of this carbon in the water which is not attributable to organic matter or sewage?—There can be no carbon estimated by this process but what is attributable to organic matter. Of course organic matter might be got in from other sources than sewage, but having regard to the large amount of sewage matter that gets in, one would naturally attribute it to the sewage.

16,450. You think that the ·5 does indicate the presence of sewage?—Yes, I do.

16,451. Although Dr. Frankland said it did not?—Although he said not.

16,452. (*Dr. Stevenson.*) This was during flood time, was it not?—It was during flood time.

16,543. Did you ascertain whether the overflows were acting at that time?—I do not know for a fact whether they were or not.

(*Mr. Michael.*) It may be taken that they were, because at all times of flood they act; they exist for that express purpose, and they act automatically. When the water rises above a certain height, they must act, because the water must go over the weir.

(*Witness.*) But it has been given in evidence over and over again, that the water above Bridge is never very reprehensible.

16,454. (*Mr. Michael.*) Does the pollution of even the worst stretch of water become excessive at any time?—It does not.

16,455. What do you think that is due to?—It is partly due to dilution, and partly to the destruction or oxidation of the sewage matter. With regard to this matter of oxidation, I should like to point out to the Commission that, supposing you take the normal proportion of oxygen in water not at two cubic inches per gallon, but at something less, at 1·84 cubic inches per gallon; upon that calculation every four million cubic feet of water would contain one ton. Now here we are not dealing with four million cubic feet, but with 2,000 or 3,000 million cubic feet carried forward at a tide; therefore we have several hundred tons of oxygen to play with.

16,456. What do you take as the mean proportion of free oxygen in the flood water at Erith?—According to our experiments, the proportion of oxygen in the flood water at Erith is reduced to about one-fourth of its normal amount, which means to say that it has expended three-fourths of its oxygen in doing something or other, in other words, in oxidising sewage; it must be that, because there is nothing else to oxidise.

16,457. (*Chairman.*) Will you allow me to ask you, because it seems very important, at what time of the tide did you take the water which you say has lost three-fourths of its oxygen?—This was the average of a series of experiments made upon the rise of the tide, which were put in evidence by Dr. Dupré, who showed you the curve they gave.

16,458. (*Sir John Coode.*) What, can you tell us, is the proportion of oxygen in salt water as compared with that in fresh water?—It is a somewhat smaller proportion; if you take fresh water at two cubic inches, it is about 1·8 that is a little less in salt water; but for the purpose of this inquiry it is practically the same. Now, if you take the quantity of flood water passing Erith upon a single tide to be 3,200 million cubic feet, and Mr. Mansergh gave it at 3,500 million cubic feet, you will find that that water actually contains 200 tons of oxygen which it has to expend, and it must have already expended 600 tons of oxygen, and having expended that 600 tons of oxygen, it must have oxidised several hundred tons of organic matter.

16,459. That is to say, it had originally 800 tons of oxygen, and had expended 600 tons, leaving 200 tons in the water?—Yes; and that would be disregarding all the oxygen contained in the river above Erith at low water.

16,460. How much sewage would the amount of oxygen remaining in the water suffice to oxidise and destroy?—You may take it that 200 tons of oxygen being sent up with the flood tide would suffice, at any rate, to oxidise over 100 tons of organic matter, while the quantity of organic matter put in at any single tide is about 50 tons.

16,461. So that you have always something more than is required to oxidise what is put in?—Yes.

16,462. That would account for the sewage not creating a nuisance in your opinion?—To a very great extent, no doubt.

16,463. (*Chairman.*) Do I understand you to mean that when the water reaches Erith it is already short of that quantity of oxygen which would be in it if it were not the return water which had already oxidised some sewage?—Yes.

16,464. When it comes back it has still enough oxygen in it to do the work that is required of it three or four times over?—Yes.

16,465. (*Mr. Michael.*) It meets with organic matter still remaining in the water, and has still left in it oxygen sufficient to do the work over and over again?—Yes; and as the effect of that, we sometimes find the oxygen reduced to about one-tenth.

16,466. (*Chairman.*) To about a tenth of what would naturally be there?—Yes.

16,467. (*Dr. Stevenson.*) Does sea-water part with its oxygen as readily for the purpose of oxidising organic matter as fresh water?—There is no reason to suppose that it does not. I do not know of any direct experiments in the matter, but that is my impression.

16,468. (*Mr. Michael.*) But you have found that the oxygen has, to a large extent, gone out of this water, which is salt water merely mixed with a large amount of upland water?—Yes, that is so.

16,469. And that the action of the oxygen must have prevented putrescence from taking place?—Yes.

16,470. There has been a certain oxidation occurring which has prevented bad results from following?—Yes.

16,471. (*Dr. Stevenson.*) We have no evidence as to how long the oxygen which has disappeared from the water has taken in disappearing?—No; the only sort of facts we have are, that there is the fresh water coming down which has about two cubic inches of oxygen per gallon—there is the sea water coming up with about its two cubic inches per gallon. Then you have a stretch of intermediate water in which you find the proportion very much less, as, for example, at Erith, where it is about one-fourth, that is to say, each gallon contains half an inch instead of two cubic inches.

16,472. Would not that seem that there is a very large proportion of organic matter below Erith to oxidise?—It would show that there was organic matter there being destroyed faster than the water could fully saturate itself with oxygen.

16,473. Below Erith?—Yes.

16,474. (*Mr. Michael.*) There of course you have continuously coming up water fully charged with oxygen to meet the wants of the water coming down which has been to a large extent deprived of its oxygen?—Yes, establishing an equilibrium.

16,475. Of course there might be such an amount of organic matter pouring into the river, that the water coming up would be inefficient to do its work?—Yes.

16,476. But that has not happened?—No; that is not the case yet.

16,477. (*Sir John Coode.*) Have you made experiments upon the quantity of oxygen in the water at high water before the sluices are opened, in order to ascertain that the sea water coming up has its full proportion of oxygen? The thought that occurs to my mind is, whether the water being left in the river deprived of its due proportion of oxygen, the sea water coming in is not deprived of its proportion of oxygen to supply the deficiency of oxygen in the water in the river before the tide comes up?—I have no doubt that is so.

16,478. Have you ever made any experiments upon the water in the river at high water before the sewage has come in?—Tables were put in by Dr. Dupré to show that. I am referring to page 66, Table 4*a* of his Tables.

16,479. (*Dr. de Chaumont.*) Are you of opinion that the power of oxidation is diminished when the amount of oxygen is diminished in the water, in a greater degree than in the proportion of the diminution of the quantity of oxygen. We have had it stated that when there was two of oxygen in the water and that was diminished to 1·5, the loss was more than in the *ratio* of 4 to 3—is that the case?—That evidence was given by Dr. Tidy. I should say we have considered that, and that my colleagues Sir Frederick Abel and Dr. Dupré, are of opinion that that is not so.

*Dr. W. Odling, F.R.S.*

26 June 1883.

I do not go quite so far as they do. I admit there are some facts which are in favour of that theory, and some facts which are opposed to it. I should think it is quite an arguable question. I should think that with the reduction of the proportion of oxygen, the oxidising power might be diminished in a somewhat more rapid ratio.

16,480. That you attribute to the oxygen being more diluted?—Yes; but I should say that in this case, the question is as follows:—It is stated that if you run sewage into 20 times its volume of water containing two cubic inches of oxygen, you destroy it in the course of a twelve miles run. Now here the question is of running sewage into about 250 times its volume of water containing half an inch instead of two inches; it is 20 times its volume with two inches, and it is 250 times its volume with half an inch.

16,481. (*Mr. Michael.*) There you have a very large surplus as the result of dilution against concentration?—Quite so.

16,482. There is another point I want to ask you about. Are you able to tell the Commission anything as to the power of the water to recharge itself up towards the normal point, when from any accidental cause such as the mixture of sewage, the normal quantity of oxygen has been reduced very largely?—That is a very important point. It is not only the quantity of oxygen in the water which it is able to act with, but the quantity it is capable of absorbing, and the quantity of oxygen it is capable of absorbing from the air is exceedingly great.

16,483. When you have reduced the quantity below the normal quantity, is there a continual tendency on the part of the water to recuperate itself from the air?—There is.

16,484. If there is any vegetation of any kind is that also a cause, especially in sunlight, of oxygen being given off from the surface?—Vegetation is an additional source of oxidation of the water.

16,485. Whether the vegetation be microscopic or otherwise?—Yes. As I have expressed myself so strongly upon this question of oxidation, I should like to make an observation with regard to one of Dr. Frankland's experiments. I should say that Dr. Frankland's experiments upon the oxidation of sewage seem to me to be of two kinds; there are those which prove nothing either one way or the other, because they are not adapted to prove anything, and there are others which prove our case, and amongst those which prove our case, I would call attention to those which are given in detail in the 6th Report of the Rivers Pollution Commission. They amount substantially to this, that he took river water, and mixed the river water with 5 per cent. of sewage; he analysed a portion of the mixture immediately, the rest was put into bottles, and he opened one of the bottles every day. Now at the end of two days Dr. Frankland's statement is, that 16 per cent. of the sewage matter was destroyed; but Dr. Frankland actually put in from four to six times as much sewage as all the oxygen in the bottle could possibly oxidise, and accordingly 16 per cent. of the actual sewage is equivalent to at least 64 per cent. of what could possibly be oxidised. Even 16 per cent. in two days is practical oxidation; but if he had gone further than he did, and put in eight times that amount of sewage, it would only have been two per cent. of oxidation upon his quantity of organic matter, but still there would have been the same actual oxidation.

(*Mr. Balfour Browne.*) Would it not have been better if my learned friends Mr. Bidder and Mr. Michael had put the point to Dr. Frankland.

(*Mr. Michael.*) We put as many points as we could think of.

(*Chairman.*) And very probably they were not aware of it at the time. (*To the witness.*) If you had been present at that time you might have instructed your counsel to correct what you say is a fallacy.

(*Witness.*) If Professor Williamson or Dr. Stevenson will please take down the figures, the oxygen amounted to ·946 in 100,000 parts.

16,486. (*Dr. Stevenson.*) That was the oxygen by weight?—Yes, and the organic carbon in the water was 2·1. Now at a very low reckoning, that would be equivalent to four parts of organic matter, so that you have four parts of organic matter as against less than one part of oxygen. And even if you allow that oxygen is capable of oxidising its own weight of organic matter, still you have in this experiment four times as much as it ought to have been subject to. I say then that even upon Dr. Frankland's explanation, a power of oxidation was manifested, even under those unfavourable circumstances, of 16 per cent. in two days; and I say that that rightly interpreted means 64 per cent in two days.

16,487. (*Chairman.*) If I understand your observation correctly, if it had remained there for a month, there would have been no greater amount of oxidation unless the water had got re-oxidised in some way?—That is so. If you calculate the amount of oxidation effected in percentages of the organic matter, it will depend entirely upon the quantity of organic matter present. The proper way to calculate it is, upon the quantity of oxygen removed, because if you take a certain quantity of organic matter upon which the oxidation comes out at 16 per cent., if you double that amount of organic matter it comes out at 8 per cent., and if you quadruple that amount of organic matter, it will come out at 4 per cent., unless you double or add to the oxygen.

16,488. (*Mr. Michael.*) Does not it come to this, that the oxygen in water is only competent to do its own proper share of work?—Yes.

16,489. Here the oxygen has been doing its work, and that is manifest by the removal of the oxygen?—Yes.

16,490. The atmosphere is constantly tending to restore the quantity of oxygen in the water, and here it is evident that there is sufficient oxygen in the water to renew the oxygen consumed by the sewage stream and to purify it?—Yes.

16,491. Now would you tell me about any smell which is given off by the sewage stream?—In warm weather the smell given off by the discharge of the sewage stream is sometimes offensive and nauseating, but according to my experience, and I have been there frequently in hot weather, it does not spread very far.

16,492. And could it spread a mile from the banks?—According to my experience it does not spread anything like a mile from the banks.

16,493. (*Sir John Coode.*) Could it do injury on the banks?—That has not come within my purview lately; but 25 years ago, I was Medical Officer of Health for Lambeth upon the river side; and in conjunction with Dr. McWilliam who was the Custom House Medical Officer, and Dr. Barnes of the "Dreadnought" and some others, we went carefully into this matter, and as far as we could make out, although the river at that time was smelling, yet there was no substantial increase of disease that one could trace to it in any way.

16,494. (*Chairman.*) What year was that?—It was in 1858 and 1859 before the sewage outfalls were opened, but when the whole mass of water and sewage which then oscillated higher up instead of low down (it oscillated between Greenwich and Westminster more especially) had a most extreme stink, and was more black than brown.

16,495. (*Sir John Coode.*) As I understand, the site of your observations at this time was at or near Lambeth?—Yes, at or near Lambeth, and down to Greenwich.

16,496. Upon the part of the river which was then affected by the sewage?—Yes.

16,497. (*Chairman.*) I should infer from what you say, that the volume of water in the river then was not sufficient to oxidise the sewage?—That is so, we had that borne out by experiments made by Dr. Allen Miller, who found that the quantity of oxygen in the

river was nil, and the colour of the mud was black. As you have been told, when the sewage is oxidised, it turns brown; when it is not oxidised, it turns black.

16,498. If I understand your observations rightly, this sewage could scarcely ever reach Woolwich in an offensive state?—If it is discharged upon the turn of the tide, certainly not.

16,499. But if it were discharged while the tide was still flowing, do you think it could reach Woolwich then in an offensive state?—I should think not, but I have not myself traced it up to Woolwich, the river gets very narrow there, and the sewage might get into eddies and be unpleasant.

(*Mr. Balfour Browne.*) There was evidence from Captain Burstal to the effect that that was so.

16,500. (*Chairman.*) When it gets to Woolwich it has travelled more than two miles along the river?—My clear opinion is, that it would not be offensive; but in the other case I was speaking from observation; whereas here I am only speaking from opinion.

Cross-examined by Mr. Balfour Browne.

16,501. To refer for an instant to the Report you made in 1858, when you were connected with Lambeth, On page 12, I see you say this:—"I am inclined to "think with Mr. Goldsworthy Gurney, that suspended "sewage if thrown into the Thames, no matter how "far down, will be brought up again by the upcast, and "if the retrogrades be not destroyed, it will be retained "in the River." That was the opinion you then came to, that sewage thrown in however far down would come up again?—With a qualification.

16,502. What is the qualification?—"If the retrogrades be not destroyed."

16503. Do you adhere to that?—I am not only of opinion that some sewage matter might get up the river, but I know as a fact, that some does get up at the present time.

16,504. But you are unable to tell his Lordship how far the sewage does get up the river so far as to be injurious?—As I say, it does not get up any distance so as to be injurious.

16,505. You have used the expression that in warm weather it becomes offensive and nauseating; how far up the river would that apply?—I have just stated in answer to his Lordship, that that would not reach so far as Woolwich.

16,506. But that you said was a matter of opinion, and not of observation?—But I can say, speaking from experience, that since the outfalls have been in existence, there has not been any smell in the water above bridge.

16,507. In the Report you have before you, you seem to attribute most of the nauseous smells not to the water itself, but to the exposure of the sewage matter upon the banks of the river, is that so?—That is substantially so, with some qualification. I was speaking then of above London. I believe the chief source of the smell even in those worst times was due to the large deposit of the mud banks which existed in different parts of the river; that those mud banks did not smell so much when they were left quiet, but that with the flow of the tide they were disturbed, and their disturbance in that way created a very considerable nuisance, and was the cause of the blackness of the river.

16,508. You said there, I see upon pages 18 and 19. "No matter at what point of the river the sewage is "discharged, you may rest satisfied, organic mud will "still be deposited upon the exposed flat banks of the "Thames"; is that your opinion now?—In essence, yes. That is to say, if you take the paragraph by itself, it bears the exact interpretion you have given it. But if you take it as a whole, the remedy proposed was increased scour, whereby the mud should not deposit upon the banks, and as a matter of fact, that portion of the bottom of the Thames which is exposed at low water, is no longer mud, but gravel. The banks are substantially clean, whereas before, there were extensive mud banks.

16,509. In that Report you criticised the Main Drainage Scheme. "In this scheme there is taken "down a great deal of natural storm water, which "should be disposed of in another way." Is it not so?—Yes. I should say that the whole purport of this Report was to show, that unless the river were embanked and the scour of the river increased, it was a matter of little consequence where you poured the sewage into it.

16,510. And that is your opinion still?—Substantially it is. I believe that now if you had the same exposure as you formerly had, the sewage water from Barking would be carried higher up the river, and a portion of the mud would be deposited upon those banks, and in hot weather it might become a nuisance but not to so large an extent as when the sewage was discharged higher up the river.

16,511. (*Chairman.*) You thought that these outlets would be as injurious to the river where we are now, as what was then going on?—What I thought was that it would not prove an effective cure.

16,512. Not even up to Westminster Bridge for example?—The tendency of light mud is to deposit with the ebb tide, and then the flood tide coming up stirs that up and carries it forwards, and no doubt there is a liability to some portion of the suspended matter being carried high up the river, unless you have a sufficient scour over the whole surface.

16,513. Do you mean by "suspended matter" the mineral matter?—No, I am speaking of the lighter portion of the suspended matter, which is mainly organic.

16,514. There is a tendency to carry it up, is there?—There is a tendency to carry up a considerable portion of it—of course the thing arrives at a balance in time.

16,515. (*Mr. Balfour Browne.*) If I understand rightly, you expected the river after these works would smell at Westminister Bridge, nearly as badly as it did before?—If you will leave out "nearly as bad," I would say so. My opinion is, and was, that there would be an appreciable quantity of mud brought up unless the scour of the river was increased.

16,516. Do you think there is now?—No, because we have an increased scour by means of the embankment.

16,517. How far does the Thames Embankment affect the Thames in London?—We have all that long piece of ground now covered by the embankment which was formerly mud bank.

15,518. But we have mud banks upon the Lambeth side still?—Yes there are some, but they are very small compared to what they were. Formerly if you dredged the river bottom it was mainly mud, now mud is the exception, and if you dredge now you find gravel.

16,519. Do not you think that unpolluted rain water ought to get in the river—for instance the rain water falling on London should get into the river in London, and not be carried down by an expensive aqueduct to Barking?—I do not think there any use in carrying the rain water to Barking if you could find an economical way of discharging it higher up.

(*Chairman to Mr. Balfour Browne.*) It seems to me that the drift of your cross-examination is to show that Dr. Odling was mistaken.

(*Mr. Balfour Browne.*) No, my Lord, I think he was right—that he was entirely right then, and wrong now.

(*Chairman.*) That is to say, he anticipated a continuation of the nuisance up the river here.

(*Mr. Balfour Browne.*) Yes.

(*Chairman.*) I understand you to say that he thinks there is one still, but not appreciable hardly.

(*Mr. Balfour Browne.*) That is so.

(*Chairman.*) Do you want to make it out to be appreciable.

*Dr. W. Odling, F.R.S.*

6 June 1883.

(*Mr. Balfour Browne.*) I did not expect Dr. Odling to admit that it was appreciable.

(*Chairman.*) But what does it matter, suppose he was wrong, I believe everybody here is of opinion, with all due submission to Dr. Odling, that he was wrong, because people are bathing in the water between the bridges. I do not know whether they purify it in any way at those baths at Charing Cross.

(*Witness.*) My opinion was that, unless you embanked the river, you would have those difficulties. The river is embanked, and the difficulties have disappeared.

(*Mr. Balfour Browne.*) But the river is not embanked throughout the whole length of London, but only for a very small piece; and you tell the Committee that wherever you have these mud banks, the deposit will take place, and will become offensive.

(*Chairman.*) I cannot see the use of it, because if Dr. Odling were to say that the river was as bad now as it was in 1857, I should respectfully hold my tongue, though I might withhold my opinion also.

(*Mr. Balfour Browne.*) Dr. Odling says that wherever you find mud banks, you find a deposit of organic mud which will become offensive; he now assumes for the purpose of his argument, that the Thames has been all embanked through London, whereas it is only partially embanked, and there are mud banks.

(*Mr. Beaumont Morice.*) And with regard to the baths I am told the water is filtered through charcoal filters.

(*Chairman.*) Would filtration take away the smell.

(*Witness.*) It would if you filtered it through animal charcoal.

(*Mr. Beaumont Morice.*) And that is what I am informed is done.

(*Witness.*) With regard to the mud, is all a question of degree. When there is a very large mass of mud upon the banks, it makes the river smell. When it is in small proportion, it is no more than the river can manage.

16,520. (*Mr. Balfour Browne.*) Would you say it is essential for the public health that the mud banks should be removed?—I say the mud banks are really so small in comparison to the mud banks which previously existed, that it is quite in the power of the river to overcome their polluting influence, which formerly was not the case, because we know the river above bridge stank.

16,521. It is your experience, I think, that the temperature of the mud banks is very much higher than that of the water?—Of course when the sun is shining upon them it is so.

16,522. And of course that leads to the rapid putrefaction of the matter upon the mud banks?—Yes; the higher the temperature, the more rapidly putrefactive change goes on.

16,523. What was the temperature of the mud banks; was it 120 degrees as compared with 70 degrees in the water. I think you stated it when you were giving evidence before the Commission as to the embankment of the River Thames?—I think that must have been a slip, 120 degrees is very high. I think it must have been either a slip on my part or a slip in the report.

16,524. I have here, "During the hot weather, the "temperature gets as high as 120 degrees, while that "of the river water is not above 70, and it is always "in such times that the smells are most unpleasant"?—It is quite possible that the mud should get to a temperature of 120 degrees with the sun shining upon it.

16,525. Is it your experience that the river does not get so well aerated in hot weather, as in cold?—I think that is the case.

16,526. And in that Report, as you told the Commission, you found that the water between Greenwich and Chelsea was very offensive?—In that year it was very offensive, and in the year preceding to a somewhat less extent.

16,527. When I am speaking of your evidence, I am speaking of your evidence given in the year 1861?—That I cannot call to mind.

16,528. You also gave evidence before the Committee which sat upon the Essex Reclamation Bill?—Yes, I think I did.

16,529. And that was after the outfalls had been opened of course. It was in the year 1865, and the outfalls were opened in 1864, do you remember that?—I dare say that was so.

16,530. Does this correctly express your view now, as it did then: "I have all along been of opinion, "and have expressed it many times, that the discharge "of sewage at Barking will not be sufficient. I know "that there are great authorities upon the other side, "but that is my individual opinion." Is that your opinion still, as it was in the year 1865?—Yes; because I had in view then the necessity of an increased scour of the river to supplement that. At that time the embankment was not made.

16,531. Personally you know nothing about the scour of the river, you are taking that from the engineers, I presume?—I was very much engaged with engineers when that inquiry took place, in some experiments which were made as to the rate of flow which was necessary to get a gravel or sandy surface, as compared with a muddy surface.

(*Chairman.*) Dr. Odling was called in that year. I have no doubt that like everybody else who does his duty well towards those for whom he was concerned, he had a bias, though an unconscious one, in their favour. No counsel ever does his duty well unless he is strongly of opinion in favour of his client. Then Dr. Odling ventured upon what we may call an opinion, not as to an actual matter upon which he could employ his skill, but a speculative opinion as to the future. In my humble judgment he was wrong, unless it is, as he says, that but for the additional scour he might have been right; but after all what do you prove upon that.

(*Mr. Balfour Browne.*) There is an entire distinction, I submit, between the advocate who has strong views that his clients are right, and a skilled witness who comes to instruct the Committee upon matters of fact. Dr. Odling was called as a skilled witness.

(*Chairman.*) But suppose he was wrong then.

16,532. (*Mr. Balfour Browne.*) I should be glad if he would say the same thing again. (*To the witness.*) But even now has the Thames Embankment increased the scour at Barking?—At Barking, the condition of things is entirely different.

(*Chairman.*) Suppose he were to say, "My anticipations have not been realized, either because I "was wrong in my opinion, or because the additional "scour or something else has obviated those bad "effects which I anticipated;" suppose he was to say that to you, how would it advance the case?

(*Mr. Balfour Browne.*) I think it would advance the case in this way, that you might think he was wrong again.

16,533. (*Chairman to the witness.*) I daresay you will admit, that like the rest of us, you have been wrong a good many times in the course of your life?—No doubt.

16,534. (*Mr. Balfour Browne.*) You said your opinion was that the discharge at Barking never would be sufficient to purify the river?—That was my evidence, and as a matter of fact something else was done in consequence.

16,535. You say now that the increased scour has altered those circumstances?—Yes, it has in the upper Thames.

16,536. Has the increased scour affected Barking one whit?—I do not know that it has, but you put in my hand a report referring to the upper river.

16,537. But this statement referred to Barking: "I have all along been of opinion, and have expressed "it many times, that the discharge of sewage at

"Barking will not be sufficient"?—"Will not be sufficient to purify the upper Thames."

16,538. You say it has not affected the condition of things at Barking?—No, but it has affected the condition of things in the upper river to which alone the question applied.

16,539. (*Mr. Balfour Browne.*) After what your Lordship has said, I will not pursue the question any further. I think Dr. Odling's admission is sufficient (*To the witness*). But I am told to ask you this, in your experiments have you traced the sea water as high up as Wandsworth?—Yes, I have.

16,540. (*Chairman.*) When was that?—It was 20 years ago.

16,541. (*Mr. Balfour Browne.*) And you also said "where the sea water would get, I believe the sewage would get back?—Yes.

16,542. Now about these chemical processes, you use the organic carbon process yourself?—Yes, I do.

16,543. In this case, have you made any analysis separately from the other chemists?—I have made one series of analyses.

16,544. Were they made with the organic carbon process?—They were.

16,545. Why were they not put in?—I have them in my pocket, they were made to check the analyses of the other side, and they come out substantially the same.

16,546. Have you ever tested the oxygen process in salt water?—I took part in the experiments which were made by Dr. Dupré, but only a minor part.

16,547. You did some part of that experiment?—Yes.

16,548. But with the exception of that, you never have tried the oxygen process in sea water?—No.

16,549. As I understand, you do say that the combustion process is a better instrument than either the permanganate or Dr. Wanklyn's process?—It is a better instrument for certain purposes.

16,550. It tells you a good deal more than either of those other processes would?—It tells you something different.

16,551. "A good deal more" is my question?—You cannot say more or less with regard to things which are irrelative; but with regard to this particular case I should like to say that it is really a question not of chemistry but of common sense. If you have any measure whatever, and apply that to Teddington water and to sea water, and find that you get a result which you may call 1, and if you then apply that to sewage and get a result which you may call 28, and you find when you apply that to river water which is a mixture of the two, that there is a gradual increase to where the sewage is discharged and a decrease from that point downwards, it does not matter for the value of the thing whether you get an absolute result; unless the measure shifts its size, it does not matter in the slightest degree.

16,552. You have not made any test with the albuminoid ammonia process?—I have not myself.

16,553. As far as the chemical evidence is concerned, that is the only evidence you can give?—No, I have been concerned with the chemists all along.

16,554. I think that what you have handed to me, (*witness's results by the organic carbon process*) supports the evidence that was given both by Dr. Frankland and by Dr. Tidy?—It is quite in harmony with the general evidence.

16,555. Now as to oxygen being taken out of the water, as I understand you find that at Erith there is a fourth of the entire amount of oxygen left in the water?—Yes, 200 tons.

16,556. 600 tons having been burnt up, as you say, in doing the work of destroying the sewage?—Quite so.

16,557. That is at Erith?—Yes.

16,558. Then did I understand you to say that the incoming tide brings up water with the normal amount of oxygen in it, 1·8 or 1·9?—I never said that.

16,559. I thought you said it was replaced by water having the normal amount of oxygen in it—do you mean that the supply of oxygen was kept up by the sea water coming in?—All I say is, that there is a body of water passing Erith twice a day, and that that body is charged to the extent of 200 tons of oxygen, and that that is about one-fourth of what the normal proportion of oxygen should be.

16,560. At that point there may be an amount of sewage still to be burnt up, using up that 200 tons?—Capable of using it.

16,561. (*Chairman.*) As I understand you, not even capable of using it. What I understood you to say was, that the return water at Erith has lost three-fourths of its oxygen?—Yes, that is so.

16,562. But that the fourth that remains is capable three times over of burning up the amount of sewage that would be poured into it from the two outfalls?—That is so.

(*Mr. Michael.*) That is in short the whole matter.

16,563. (*Chairman.*) You admit that the return water, which I will not call "fouled," has been operated upon by the sewage to the extent of having three-fourths of its oxygen taken from it?—Yes.

16,564. (*Mr. Balfour Browne.*) Under those circumstances the sewage which has come out of the outfalls in the past has eaten up three-fourths of the available oxygen in the water?—Yes.

16,565. Under those circumstances how can you say that the 200 tons, that is the one-fourth which is left, is capable of disposing of the sewage coming out of the outfalls after the previous sewage has disposed of three-fourths.

(*Chairman.*) He does not say that the three-fourths had been taken out by the previous discharge of sewage, but that discharge after discharge having been mixed with the river water, upon each return of the tide, he finds it deficient in three-fourths of its oxygen but having the one-fourth in it.

(*Mr. Balfour Browne.*) If so, there could be no sewage in the water, because if the 600 tons is capable of eating up all the sewage in the water at once, there could be no deficit. (*To the Witness.*) Now in your table you assume 200 tons in the low water which has to come up the river—this is when it comes up the river. Now look at your own table at page 68, instead of being one-fourth here, I find that at one point you give the cubic inches of oxygen, not at one-fourth part, but at one-twelfth part.

(*Chairman.*) Where is that?

(*Mr. Balfour Browne.*) At low water. And that is the water which he says is pushed up by the tidal water.

(*Chairman.*) No, the witness takes the average.

(*Witness.*) It varies from 10 per cent. up to over 40 per cent., and we have taken it at 25 per cent. as the average.

16,566. (*Mr. Balfour Browne.*) But at certain periods, it is as low as 10 or 12 per cent.?—Yes, and at certain periods it is as high as 42 per cent.

16,567. It is that low water which is in the river when the oxygen is one-twelfth part, which goes up and meets the sewage?—I do not follow you.

16,568. It is not that water which goes up and is pushed by the tidal wave past the outfalls into which the sewage is discharged?—Yes, with a great mass of sea water in addition.

16,568. Is it your impression that fresh sea water comes from Southend every tide?—Some does.

16,570. That is your impression?—I know it.

16,571. Are you giving your evidence under the impression that sea water comes from Southend past the Barking outfalls every tide?—The great mass of course does not, but some does.

(*Chairman.*) I do not know that the witness is giving his evidence under that impression. He says he has ascertained that on the average the water which passes Erith upwards has lost three-fourths of its oxygen, but has got the other fourth.

(*Mr. Balfour Browne.*) But I asked him whether, taking it at the worst condition, that was not the water which would pass the outfalls, and he says

*Dr. W. Odling, F.R.S.*

26 June 1883.

yes, that water with some fresh water which has come into the river at Southend.

(*Witness.*) I said, with the great body of brackish water which exists all the way from Southend to Erith.

(*Chairman.*) I suppose the water which is off Erith at low water, in all probability, at high water has got above Greenwich.

(*Mr. Balfour Browne.*) The oscillation is just 12 miles.

(*Chairman.*) It is not into that water alone that the new sewage is discharged, but it is discharged into that which has come up during the five hours upward tide.

16,572. (*Mr. Balfour Browne.*) Yes, the sewage is discharged into water which received at any rate a portion of the previous discharge. (*To the witness.*) Now let me ask you another question with regard to that. I did not catch what your answer was to the question put by Dr. de Chaumont. Is it the fact that in consequence of dilution, the oxygen looses its power?—I said that there were some facts which rendered it probable that it was so—and that there were other facts which were opposed to that—that my colleagues, Sir Frederick Abel and Dr. Dupré, came to the conclusion that its power was not diminished disproportionately. I did not give an opinion on the one side or the other, but I said that it might be.

16,573. With regard to the oxygen, is it your opinion that much oxygen is taken up directly by water from the atmosphere?—Undoubtedly.

16,574. Is it not the fact that in rivers a large portion of the oxygen is got from vegetation?—It must be; but when a river is like the Thames at Teddington, fully saturated, it cannot take up any more.

16,575. But below Teddington there is no vegetation to supply any void that may be made by the sewage, is there?—Yes, there is a great amount of such growths as diatoms.

16,576. Do you think that they add anything in the way of oxygen?—I do not know anything about that practically; but I know if you pour water through the air you will get it absorbing oxygen most rapidly.

16,577. Is not the oxygen absorbed from vegetation the most active form of oxygen?—It has been stated, but I do not know whether it has been established, that the oxygen given off by plants is in a more active state.

16,578. You do not dispute it, do you?—I neither admit it, nor dispute it.

16,579. Now Dr. Frankland's experiments are given in the 6th Report of the Rivers Pollution Commission?—Yes, they are.

16,580. You have known of them for some years?—Yes, I have.

16,581. You were aware of them, were you not, when you gave evidence upon the Cheltenham Water Bill in 1879?—I was aware that they had been made.

16,582. And the question there was as to the pouring of the sewage from the town of Tewkesbury into the River Severn?—I may say that I was reading over Dr. Frankland's evidence upon this matter the day before yesterday, and it was only then that I came upon the point I have made to-day.

16,583. But you then followed Dr. Frankland in giving evidence as to the Severn as a source of supply upon to the town of Cheltenham?—I may have.

16,584. Those experiments were referred to by Dr. Frankland in his evidence in the Cheltenham case, and you did not then take any exception to them?—I did not. I never found out their flaw really until the day before yesterday.

16,585. But you came and said you agreed with Dr. Frankland upon that occasion. Now let me ask you this, did you not in that case say that it required a very long flow of a river to dispose of sewage?—If you will give me the question and answer, I can tell you. I do not remember it otherwise. My experience and my belief is that it does not require a very long flow.

16,586. Do you remember Dr. Frankland repeating what he had said before, that no river in England was long enough to dispose of sewage?—I do not know whether he said that, if he did, I do not agree with him.

(*Chairman.*) Did not somebody cross-examine Dr. Tidy for the purpose of showing that he had said that in a very short course the river ran itself pure.

(*Mr. Michael.*) Yes.

(*Chairman.*) The result of this cross-examination is to show that Dr. Odling has said something upon a former occasion inconsistent with what he says now. Surely we may rely upon Dr. Tidy's evidence upon this matter, that the water would purify itself.

(*Witness.*) I have never said anything inconsistent with that.

(*Mr. Michael.*) The question in the Cheltenham case was taking the River Severn into Cheltenham to supplement the supply which was then given to Tewkesbury from Cheltenham; and the question was whether it could be taken into Tewkesbury in a fit state.

15,587. (*Chairman.*) Did you say it was not fit?—I do not remember.

(*Mr. Balfour Browne.*) Dr. Odling distinctly said it was not fit. The whole question turned upon this, whether the river in running down from Tewkesbury, where it took the sewage to Cheltenham, where they took the water from it, had not disposed in the interval of all the sewage.

(*Chairman.*) I cannot help reminding you of what was said by Professor Abel. I asked him whether he thought the water would be fit to drink after it had run 20 miles, and he said, no, I can say that the offensive smells would be done away with, but I cannot say the water would be fit to drink.

(*Mr. Balfour Browne.*) I was not asking whether the water would be fit to drink, but whether in a certain flow it would be purified to a certain degree.

(*Chairman.*) The evidence is not that the sewage is annihilated altogether, but that the offensive parts are rendered inoffensive by conversion into different substances.

(*Mr. Michael.*) The whole matter turned upon this, not as to the chemical destruction, but as to the survival of certain germs which have a tendency to create disease.

(*Mr. Balfour Browne.*) I beg your pardon, it had to do with the chemical destruction by oxidisation.

(*Colonel Ewart.*) And the conditions of one river would differ from the conditions of another as to the width, and whether there were weirs, and also as to the vegetation upon the banks.

16,588. (*Mr. Balfour Browne to the witness.*) Do you think that a running river such as the Severn, with vegetation in it, and which is ærated by weirs and other matters of that sort, would be more likely to dispose of the sewage than a tidal river such as the Thames?—I do.

Cross-examined by Mr. Beaumont Morice.

16,589. You stated that you could not tell how far the sewage smell extended; how far did you go down for the purpose?—I have been there repeatedly in the last year or two, and also some years ago in 1868 and 1869, and my experience certainly is that you cannot recognise the smell from the sewage a quarter of a mile off.

(*Chairman.*) I think we are fairly entitled to say we can only allow one cross-examination as to the same matter. I rather think you represent Erith more particularly.

(*Mr. Beaumont Morice.*) I do.

(*Chairman.*) If there were anything relating relating to Erith particularly, you will be entitled to ask as to it, but not to cross-examine as to the question generally.

Examined by the COMMISSION.

16,590. (*Dr. Stevenson.*) I think we have had it stated, I do not know whether in evidence or not, that the discharge of sewage into salt water creates a greater smell or nuisance than if it is discharged into fresh river water; do you know anything about that?—I do not know anything about it definitely, but if sewage is discharged into sea water in sufficient quantity to be putrefactive, I should think it probable that the nuisance would be greater in sea water than in fresh water.

16,591. Do you think that the large amount of salt in the water at Barking and Crossness, where there is from half sea water to a sixth or a third, would retard the putrefaction?—I think it would retard the putrefaction, but I see no evidence to think that it would retard the oxidation. At the same time I do not call to mind any definite experiments upon which I should form that opinion. I only speak from a general impression.

*Dr. W. Odling, F.R.S.*

26 June 1883.

The witness withdrew.

Mr. HENRY CLIFTON SORBY, LL.D., F.R.S., called in; examined by Mr. MICHAEL.

*Mr. H. C. Sorby, LL.D., F.R.S.*

(*Mr. Michael.*) I propose to put in a report made by Dr. Sorby which contains his evidence, and I then can take his evidence very much more shortly than I could otherwise. (*Copies of the report were handed in. See Appendix CB.*) I propose only to give you a summary of the mode he has adopted, and the results he has arrived at.

(*Chairman.*) It is the only mode in my opinion in which to give this class of evidence to us, and as a justification of these details for it is impossible to carry in our minds all the details.

16,592. You are a Fellow of the Royal Society and of a great many other Societies, and you have devoted a great deal of attention, have you not, to microscopic inquiries?—Yes, for more than 25 years; and I may say that I believe I am acknowledged as being the first person who applied the microscope to the definite structure of rocks, and to the structure of loose deposits, like sand and mud, for geological and other purposes.

16,593. When did you undertake an inquiry into the mud, and the deposits which are to be found in the water of the River Thames?—I think it is three years ago, at the time of the inquiry into the origin of the Crossness banks.

16,594. You have devoted a considerable amount of attention to the subject, have you not?—Yes, as much as my time would permit.

16,595. Since that time, in 1882, I think you have lived for many months upon the river, investigating the matter?—A number of specimens were supplied to me by the Metropolitan Board of Works, about the middle of March, and I studied them until about the first week in July, when I came to the conclusion that it was very unwise indeed to rely upon the study of specimens, which I had not collected myself. There were certain questions I could not at all understand, and I thought it would be far more satisfactory to come up in my yacht, in which I live for a great part of the summer up the Thames, and carry on my investigations in my own way.

16,596. And day and night during the warm part of the year you lived off Erith?—I lived for a month off Greenhithe, and studied the river there, and I then came up to Erith and stayed there a month, never sleeping on shore a single night, but carrying out my investigations in the yacht or in a boat.

16,597. This year have you done the same thing?—I have been a fortnight at Erith, and a fortnight at Greenhithe.

16,598. I am glad to see you are not destroyed; did living at those places injure your health in any way?—Not in the least; there is not one of my crew who has the slightest fault to find with the river.

16,599. Do you use the water of the Thames at Erith?—We do not use it to cook with.

16,600. But for any purposes?—Yes, for washing the decks and other purposes; the only objection is when we are close to the tide edge, where there is the sort of scum which always comes down the river; we use the water at other times for washing the decks.

16,601. Will you tell the Commission, shortly, what was the problem which you addressed yourself to solve, what was the object of your inquiries, what did you endeavour to do first?—In the first instance, I examined a series of specimens collected from Hammersmith, right away to Gravesend.

16,602. What sort of specimens were they?—They were specimens of mud deposited from the water. I have not in any way studied the soluble materials of the river.

16,603. Do you mean that you took water, and allowed it to deposit?—Yes, I took water and allowed it to deposit, and then that mud was investigated by the microscope.

16,604. Have you an apparatus by which you are enabled, through very small meshes, about 120 to the inch, to pass 50 gallons of water, and catch the whole of the suspended matter in that 50 gallons?—Yes, but that apparatus was not used until within the last six weeks, my investigations last year were conducted by another method altogether.

16,605. You endeavoured to find all the matters which are held in suspension in the water?—Yes.

16,606. And also you directed your attention, did you not, to the various muds which are found at various sites all the way down the river?—My principal inquiry has had reference to muds held in suspension. I examined some mud at the side of the river, but I was very soon convinced that an examination of those muds could not be carried on unless you collected the specimens for yourself; because the character of the mud upon the surface is entirely different to what it is half an inch or an inch below the surface, and you require to know exactly where it comes from.

16,607. What is the difference as regards the surface of the mud, and what does it arise from?—In some cases the surface of the mud is old material which has been exposed and oxidized, and that I think we need not regard. But the mud I have especially studied is that which has been recently deposited upon the surface; and I found by studying that, that it is materially different from what you meet with one or two inches below.

16,608. In what does it differ; is there any vegetation upon the surface?—It is a very complicated question; but at Erith I have remarked very commonly upon the surface that you have a very large number of desmids and diatoms.

16,609. What are they?—Desmids are as it were diatoms which have not silicious coverings. Those desmids and diatoms and conferva, which abound in the river, are well-recognized plants, about which there can be no kind of doubt.

16,610. Either maritime or fresh water?—Yes, living in fresh or brackish water.

16,611. Have you found a large number of those in your observations?—I may say the brown colour of the mud upon the surface (the Commission will remember that the mud has been described as being of a disagreeable black or dark brown colour) is due to the countless thousands of desmids and diatoms. I may say I have collected the mud and kept it in glass beakers, and you can see that those little plants do not like to be below the surface; they wriggle up to the top, and there they multiply. I find clearly that the brown material you get upon the surface of the mud is entirely composed of desmids and diatoms.

*Mr. H. C. Sorby, LL.D., F.R.S.*

26 June 1883.

16,612. Those little matters, though they are plants, have means of motion; they attach themselves to the surface, which better suits their habits?—Yes.

16,613. Have they any influence upon the oxygen of the water?—Yes, they contain a large amount of chlorophyll. I have for many years paid attention to the colouring matter of animals and plants by means of the spectrum-microscope, and I find that those desmids and diatoms contain colouring matter of certain groups of algæ. Although they do not look green in their natural condition, you can dissolve out the yellow colouring matter, and then leave the diatoms as green as any plant you could wish to see. The number of those upon the mud and in the river is enormous at particular times of the year, and algæ and all plants, when exposed to the sunlight, give off a considerable amount of oxygen.

16,614. You have directed your attention, have you not, to ascertain whether you could discover by the microscope the quantity of sewage matter which was in the suspended matter of the water or in the mud?—The plan I have adopted is to a very large extent new. I do not know that the microscope has ever been employed in a definite manner for quantitative work of that kind until I employed it in the case of the Crossness Bank; and I may say that by employing that method, in the course of a few days I came to almost exactly the same conclusion with regard to the origin of the Crossness Bank as that which the arbitrators came to after holding their inquiry.

16,615. Will you explain the mode you adopted in order to determine what were the characteristics of the suspended matter in the water?—Do you mean with regard to the mineral or with regard to the sewage matter?

16,616. I refer to the sewage matter?—The plan I have adopted is very simple, though, strange to say, as far as I am aware, it has not been adopted before; it was to ascertain what might be looked upon as the characteristic materials of the sewage, that is to say, substances which are not found in the mud of rivers, which are in no way contaminated by sewage. I have drawn a few diagrams just roughly to illustrate my meaning (*a coloured diagram was exhibited*). That is a diagram to illustrate what I will assume to be pure mud, with no sewage contamination whatever. In that we have a number of objects, but none of those which are specially characteristic of sewage. I suppose that to be entirely mud, and nothing else. I will explain the method I have pursued, in which I adopted manipulations which I need not, perhaps, explain in detail, because it would occupy too much time. I may say, that I have the means of determining, by counting the number of different objects, in an equal volume of different material. I know, by suitable experiments, the density of those different materials, and therefore I am able to calculate what would be the number of those different objects in a given weight, which I call "the unit by weight." I then find the most characteristic objects in sewage matter, which are, in the first place, those which are characteristic of the road drift, and the materials derived from the droppings of horses.

(*Chairman.*) Must we not give Dr. Sorby credit for investigating the thing properly unless he is cross-examined to it, and let him tell us his results without giving us the details of his process.

16,617. (*Mr. Michael.*) It is an entirely new mode of investigation, and I tell your Lordship I will take it as shortly as possible, to enable the Commission to understand his method. (*To the witness.*) What are the special matters you have looked for in sewage?—I have taken first, as being characteristic of sewage, the road drift, and the material derived from the droppings of horses, and the most characteristic features that I find are the hairs of oats. I show in this report that the character of the road drift in London can be very well expressed in terms of the washing of the droppings of horses and the ordinary mud, that is derived from the disintegration of the road. I have found upon the average that the horse droppings contain a great number of the characteristic objects which are given by sewage.

16,618. With regard to the sewage matter, that contains a certain amount of human excrement necessarily?—Undoubtedly, and I have directed special attention to the determination quantitatively of the amount of detritus of human fœces. I have described in this report the manner in which I have studied human fœces, and I would say that what I call a unit of human fœces, contains a large portion of undigested muscular tissue, from the meat consumed, for example; and with regard to that I may point out what is important, viz., that the undigested muscular tissue which is found in that human fœces is not in the condition in which it is found in roasted flesh, it has undergone such a process that you cannot digest it successfully by a warm acid solution of pepsine in which you can easily digest cooked meat. Those fibres which form a part of the human fœces are not to be acted upon by that, and they resist also the action of dilute caustic potash.

(*Chairman.*) Is this witness going to show that there is, or is not, any sewage is mud.

16,619. (*Mr. Michael.*) The witness is going to show, according to his process, the nature of the mud all the way from Teddington to Southend, but I will take it shortly. (*To the witness.*) You adopted a certain microscopical mode, taking as the basis the quantity of fœces apparent under the microscope, and the droppings from the horses in the street?—Yes.

16,620. Did you make a series of investigations to determine what was the percentage of those substances to be found all the way down the river?—Yes.

16,621. Will you give the results of what you ascertained?—This is a diagram illustrative of the mud in Erith (*exhibiting the same*). You will notice in the pure mud which you get in the Essex rivers you get none of these objects.

(*Chairman.*) We should prefer to have your results, and not your processes.

16,622. (*Mr. Michael.*) Will you tell us what are the results you obtained, beginning at Teddington and going down?—I applied this method which is described in the report, to the whole length of the river, and I found that the results varied according as I took into consideration the mud itself, or the amount of this material present in the water. If I took the mud itself, to my great surprise I found that the amount per cent. of the detritus of human fœces was much greater in the mud above the weir at Teddington than in any part of the river below. It will be seen that it is greatest at Teddington and gradually decreases. On the contrary, the amount per cent. of the washings of horse excrement decreases till you come towards London, that it runs up to its great maximum at London Bridge, then it runs down again, and again runs up to a small maximum off Barking Creek, and then decreases down to the sea, that is the quantity per cent. in the mud.

16,623. Now what is the quantity found in the water?—If you refer to the diagram No. 5, you find that the amount of detritus of human fœces in a given quantity of water, increases till you get to London Bridge, then it decreases, and again runs up to another maximum between Erith and Barking Creek, and then decreases to the sea.

16,624. (*Chairman.*) It decreases from London Bridge?—It decreases between London Bridge and lower down. Then with regard to the amount per gallon of the washings of horse excrement, it increases to a very large maximum at London Bridge, it drops sharply to Blackwall and then decreases regularly to Sheerness, so that if you take into consideration the quality of the mud alone, you find it really worse above London Bridge than below, but if you take into consideration the quantity per gallon of water, the maximum point is at London Bridge.

16,625. (*Mr. Michael.*) Have you made investigations also as to any destructive influence which was exercised upon the sewage matter by microscopic animals which you found in the water?—I may say

I was very much struck with the enormous number of the excrements of minute crustaceans, entomostraca mainly. I have carefully examined that question, and at page 13 I give the number of those excrements which can be counted in a given unit weight of the mud. At Hammersmith it is sometimes as much as 1,100 in the one-twentieth part of a grain, and the average number of such excrements in the surface water of the river is 166. But at Erith, taking into consideration the entire depth of the river, in August the average number in the one-twentieth part of a grain of the mud is 360, but in May it was only 240. I may say I found there was an inverse proportion between the amount of detritus of human fœces at Erith and the number of those excrements. I found that in summer when there was a large number of those excrements of minute crustaceans there was a much smaller quantity of the detritus of human fœces, but in winter when those animals live to a very small extent, the detritus of human fœces existed to a much larger amount. It would appear that in summer three-fourths of the detritus of human fœces are removed before they get to Erith, and the conclusion I came to from my observations was this, that these minute animals live upon the organic matter which is contained in the mud. As far as I could ascertain from the microscopic structure of their fœces, I have come to the conclusion that sometimes they have an imperfect digestion. I could see portions of the finely granulated matter into which human fœces decompose, but as I was not satisfied with the theory I was desirous of ascertaining the facts by actual experiment, so at Greenhithe six weeks ago I collected a number of these entomostraca and put in with them a small portion of human fœces, and directly it was in they attacked it; they evidently knew perfectly well what it was, you could see them at it. I have kept a number of them for six weeks, and you could see that they are healthy and happy and in good spirits; you could see them eating the human excrement all the time.

16,626. (*Chairman.*) What is the size of these things?—They are very small, but then they are very numerous. This (*showing a tube*) shows about 100, found in the quantity that I collected upon one occasion.

16,627. (*Mr. Michael.*) What are those?—Those are Cyclops, and these (*producing another tube*) are Daphne; they were twice as numerous at Erith as at Crossness.

16,628. You would say that they exist in such enormous quantity as to exercise a large influence in destroying the fœces contained in the water?—The enormous amount of them is so surprising that I almost hesitate to convey any idea of it. I find taking the whole depth of mud at Erith the total number of the excrements of these small crustaceans would be about 6,000 per grain of mud.

16,629. (*Prof. Williamson.*) And how many would there be of these little beasts?—That varies according to the condition of the tide, but the conclusion I have come to is this, that the maximum number at Erith in the summer, and later on in the year, would be about 25 per gallon, and that the amount of human excrement at the time present in the water for their food would be less than $\frac{6}{1000}$ths of a grain, and it must be recollected that this $\frac{6}{1000}$ths of a grain of human excrement would include parts which they could not possibly eat or digest, they would only feed upon certain portions; in fact, there would certainly not be more than $\frac{1}{200}$th of a grain per gallon as food for 25 of them. So I feel sure that these little creatures must, although they are small, play a very important part, and be in number fairly comparable to the material they have to deal with.

16,630. (*Mr. Michael.*) Have you also found that anellids, and other mud worms, perform a very important part in disposing of the animal matter that may be found in the mud?—I have no doubt whatever that the small worms which you find in the mud play a most important part in the destruction of the sewage.

16,631. How have you arrived at that conclusion?—I have not made any actual experiment, but they are very numerous. Mr. Charles Darwin has shown what a very important part the earth worms play in the production of vegetable earth, and in the same way these anellids perform the same function in the water as the earth worms do upon the land.

16,632. Have you collected samples of the mud?—I have collected the mud in a glass beaker, and have observed the worms wriggle through it in making their countless holes, and I have not the slightest doubt that their nutriment is the mud which, like the earth worms, they swallow and eject, utilizing the organic matter present. That is the only source of food which they could have, and I think that is the principal cause of difference between the character of the mud at the surface and a little way down. At the surface you find it contains a vast number of the excrements of small animals, but if you go a little way down you find they are all decomposed and gone, and that there is no trace of the characteristic components of sewage, and I take that as very much due to the action of these worms.

16,633. Do you find a difference with regard to the amount of suspended matter upon the surface, and at the bottom of the stream?—That depends upon the condition of the tide. My experiments were made at half-ebb and half-flood. In some cases the current runs so extremely strong at spring tide, that there is occasionally as much mud held in suspension at the surface as at the bottom; but as a general rule there is much more mud held in suspension near the bottom, and there is a different distribution of the constituents, as I have shown in my report.

16,634. Is there a great deal of difference in the action of these animals, in your experience, in the summer and in the winter time?—I think there can be no doubt about that, because the number of excrements in a given quantity of mud varies greatly, and varies in an inverse proportion to the amount of human fœces contained in the mud.

16,635. (*Chairman.*) Do you mean that you find the excrements of these creatures?—You can see them perfectly, but I did not like to make a drawing of them, because everybody would laugh. They are so exactly like what we are familiar with upon a very small scale.

16,636. (*Mr. Michael.*) You produce, I believe, a sample of the mud which you collected by means of a small strainer?—I do (*showing the same*). I may, perhaps, state the conclusion I came to, and which is given in one of my tables here. The plan I adopted was to collect the material at mid-stream, at half-ebb, and half-flood. I collected the material at the surface, half-way down, and at the bottom. I determined the amount of the material, and by the microscope I determined the percentage of sewage matter, and by multiplying the two together I obtained the amount of material that is derived from sewage. By staying on the spot for a month I was able to ascertain the laws of the variation of this material. I found the main factors were the tide and the rainfall, but that on the average the amount of the sewage material carried up by the flood tide was 40 per cent. of that carried down by the ebb tide, but that that varied according to the tide, and that at spring tides the amount of sewage material carried up was only 24 per cent. of that carried down. Those two bottles contain the amount of material that will not pass through a sieve with apertures of a two-hundredth of an inch in diameter. All the normal mud of the river passes through the meshes. You have here portions of straw and hairs, and other matters, and other not truly river particles, that will not pass through. (*The witness exhibited two sample bottles.*) One of those bottles shows the total amount of material more than $\frac{1}{200}$ of an inch in diameter contained in 50 gallons at half-ebb, and the other the same amount at half-flood, at spring tide.

*Mr. H. C. Sorby, LL.D., F.R.S.*

26 June 1883.

16,637. In order to make a determination, have you not also taken out, and will you explain to the Commission, the sand of the sewage and the sand occurring in the banks of the river under the various conditions you have dealt with?—The method I have employed now is pretty nearly the same as I employed in the Crossness Inquiry. That was founded upon the difference between the amount of flint sand and quartz sand, and in order to show how those can be distinguished I have prepared this diagram (*showing a coloured diagram*). In using polarised light and rotating the glass round, you get it either light or dark, as the case may be, and that shows quartz. Now flint, on the contrary, has a compound optical structure, and exhibits light at all times.

16,638. So that you are at all times able to determine between quartz sand and flint sand?—Yes.

16,639. And is that of importance in determining this question of the description of sand found in the banks?—I find in the road drift there is a very large amount of flint as compared to quartz. The sand of the sewage I found contained about 14 per cent. of flint. I counted a large number of the grains, so as to enable me to ascertain the ratio, but you will find that the normal sand of the river far below London, the old sand that was deposited to form the saltings, contains only 1 per cent. of the flint, and that enables you to determine approximately the amount of sand derivable from sewage, which is now contained in the mud deposited at Erith. That is the sand from the drift (*showing a sample*), and that is the sand from the sewage (*showing another sample*); that is the sand from Coalhouse Point (*showing a third sample*). I also exhibit samples of the sand from the saltings, and of the sand from the banks at Erith. (*The same were exhibited.*)

16,640. (*Chairman.*) Has the road drift been brought down by the sewage?—The sample you have before you is from the road drift found in the sewage.

16,641. (*Mr. Michael.*) Your object in showing these four specimens is this, is it not: You begin with the road drift, and then you come to the sewage; do you find the same kind of sand as is characteristic of road drift in the sewage?—Yes.

16,642. Then do you take as a specimen what is the natural condition of sand in the saltings?—Yes.

16,643. Then do you take the mud banks complained of at Erith, and do you find in the mud banks exactly the same sand as that which is found in the old saltings in the bed of the river?—Yes.

16,644. And considerably differing from the sand you find in the sewage?—Decidedly.

16,645. Now I will ask you as to the general conclusions at which you arrive?—May I beg to be allowed to make one remark first. By studying the quartz the conclusion I come to is that the amount of sand derived from the sewage at Erith is 3·24 per cent., that is to say, sand of sewage origin. By studying the mud by the other method, that is to say, by the hairs of the oats, the average percentage was 3·29; so that you have 3·24 by one method, and 3·29 by the other.

16,646. That is so close an agreement as to give you considerable confidence in the results you obtained?—Yes, but I may say that that refers not to the objectionable constituents of sewage, but to the mineral matter.

16,647. Have you found that the quantitative method you have employed may be relied upon?—I find it is far more accurate than is requisite for the purpose before us.

16,648. Has it enabled you to obtain an idea of the character of the contamination in various parts of the river as set out in this report?—Yes.

16,649. Have you arrived at the conclusion from the mode you have adopted that a large portion of the more objectionable ingredients of the sewage are removed, especially in summer, by the action of minute animals?—Yes.

16,650. And that there is a very large biological influence exercised?—Yes.

16,651. Your fourth conclusion is, that the combined effect of these, and of the large volume of the river near the outfall, is to rapidly reduce the percentage of sewage in the mud and in the water to considerably less than what it is above the outfalls?—I have here a diagram which shows the reduction in the amount of the detritus of human fœces and horse droppings from the streets; it shows an extremely rapid reduction in quantity, the one being due to dilution and the other to consumption by minute animals, and to decomposition.

16,652. Then you find, "That the unregulated "introduction of impurities from various sources "above the outfalls, where the volume of water is "relatively small, causes the river between London "Bridge and Blackwall to contain more impurity "per gallon of water than below the outfalls, where "there is a regulated discharge of a larger amount"?—The facts certainly show that.

16,653. Do you find, "That the greater amount of "impurity near London Bridge is not due to material "drifted up from the outfalls"?—You find the amount of impurity in the half ebb at London Bridge and at low water is very much greater than at half flood and at high water. Other facts show that that method can be relied upon.

16,654. (*Chairman.*) The other thing is that it diminishes between London Bridge and the outfalls? The detritus of human fœces does not materially decrease, but the road drift decreases very rapidly.

16,655. What strikes me is, how that can possibly be so?—I think it can be explained by the increased volume of water. There is a diagram here which shows that if the river were of uniform magnitude there would be an enormous increase off Barking Creek and Crossness; but when you take into account the increased volume of water, it is accounted for. If the river had remained at even volume this line (*pointing to the diagram*) would be the result; but the lower line is what it actually is, being due to dilution.

16,656. (*Mr. Michael.*) You say you believe that the greater amount of impurity near London Bridge is not due to material drifted up from the outfalls?—I think so, because you find that the water which comes up is much more pure than that which comes down. I have paid very great attention to that point, and my observations all bear it out in the most conclusive manner, both when you study the water upon the surface and in the whole depth of the river.

16,657. Can you explain why the effect of the discharge is so small, except over a limited area?—I think it must be due to the enormous dilution and to the destruction by chemical and vital action.

16,658. You have stated that the mud deposited at Erith, instead of being sewage mud, differs only by 3·29 per cent. from the ordinary saltings mud which you would find in other parts of the river if there were no sewage?—That is so.

16,659. Is it true that the results you have given apply to dry weather?—My experiments were carried out when there was hardly any rainfall, and I afterwards also examined samples collected at a time when there was a large rainfall, and I found the reduction of impurity was very great indeed. I found that off Woolwich and Barking Creek the reduction was to about one-third.

16,660. More than one half?—Yes.

16,661. And all those things have been the result of personal experiment upon the river for three months, and before that time?—Yes.

16,662. (*Chairman.*) What is the mud upon the banks of the river composed of, say at Erith; you say that sand (*exhibiting one of the sample bottles*) is a part of it?—Yes.

16,663. That can only be held in suspension, I suppose, if you put it in water; it will not be in solution, I suppose?—No, in suspension.

16,664. What are the other constituents of the mud?—The ordinary constituents of clay and shale

deposits; the material produced by the decomposition of feltspar and other material, associated with organic and other matter, and of course there are a number of other things, such as diatoms, and so on, contained in it.

16,665. I think you say that there is about one per cent. of sewage matter in the mud?—The mud at Erith in the summer now contains upon the average about 4 per cent. of the indestructible material of sewage, but three-fourths of the readily decomposed material has been decomposed before it gets to Erith.

16,666. But I am speaking of the mud at Erith; what is that composed of?—Four per cent. of the indestructible part of ordinary sewage and one per cent. of the destructible.

16,667. The indestructible being innocuous?—Yes.

16,668. That does not include the hairs of oats, does it?—Yes, it does.

16,669. That is indestructible?—You can detect them as far as Yantlet Creek; they are not dissolved by nitric acid, so I look upon them as comparatively indestructible.

16,670. What is the other one per cent.?—As far as my investigations go, the mud which is carried down the river contains in summer about one per cent. of detritus from human fœces.

16,671. When you say "detritus," it has not been altered, not oxidised, or anything of the kind?—No, it is in the normal condition.

16,672. Only granulated or disintegrated?—Yes, quite so, and some are larger fragments.

16,673. Why would not that smell if it were exposed to the air?—You perceive the amount is very small. That is not the amount that is deposited; there is not so much as that deposited upon the side of the river.

16,674. But I am talking of the mud itself?—The mud deposited upon the shore contains considerably less than that; it contains from one third of a pound to half a pound per ton.

16,675. That would be about one forty-fifth per cent. or less, and that would not smell, you think?—That I am not prepared to say. I could not smell it; that is all I know. I lived at Erith six weeks, and I can say that the only nuisance we experienced there, was the coal dust from Messrs. Beadle Brothers' coal wharf.

*Mr. H. C. Sorby, LL.D., F.R.S.*

26 June 1883.

16,676. But you have been upon the shore of course?—Yes, I have.

16,677. Upon the mud?—I have not been very much upon the mud, because I am upon the river almost all the time, and I do not go upon the mud except when I go to collect material, but we never detected anything that was objectionable.

16,678. You do not know that it did not smell?—We did not smell it, at all events.

16,679. But you were not upon the mud?—We were upon the mud collecting materials. My men all laughed at the smell of the river, but they do complain of the smell of the factories.

16,680. (*Sir John Coode.*) Where you said 1 per cent. of detritus (I think you said 1 per cent.), you did not mean detritus in the sense of deposit from the road washings, but you meant 1 per cent. of solids in the sewage?—I meant 1 per cent. of the detritus of human fœces, the insoluble portions, and 4 per cent. of the material that is of an indestructible character.

16,681. (*Prof. Williamson.*) You mentioned the circumstance that you found a considerable quantity of the excrement of these small animals, the entomostraca, and that you ascribed that to the transformation of the human fœces which they had consumed, so that those represented a smaller quantity than the substance they eat; now does this excrement represent organic matter which might become offensive?—I am unable to say that; one knows necessarily that if they live upon the material they must consume a considerable portion of it, and that their excrements do not contain the whole of what they eat. No doubt they must digest some portion of what they eat, but they do not completely digest it all, and their excrements might possibly be the source in large quantities of disagreeable results.

*Mr. Beaumont Morice* applied for leave to postpone his cross-examination, upon the ground of the amount of evidence put in by the witness in the form of a report.

Adjourned to to-morrow at half-past 12 o'clock.

# FORTY-FOURTH DAY.

## Wednesday, 27th June 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S. IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

(*Mr. Webster.*) My Lord, as the evidence is drawing to a close, might I mention one matter upon which I would ask for information. Mr. Law suggested on the 26th May that, though there had been a continuous rainfall, there had been no overflow. I put it to him upon instructions that upon that day which he mentioned, the 26th May, the Blackfriars sewer had run strong with sewage during the whole day; and your Lordship was good enough to say that I was perfectly right in pointing that out to him, and requested that inquiries might be made to ascertain whether that was the fact. I would ask my learned friend, Mr. Norman Bazalgette, whether he is able to state that as a fact; if not, I must get the pierman at Blackfriars to attend here to prove it.

(*Mr. Norman Bazalgette.*) Mr. Law is not here, but I will send for him.

27 June 1883.

(*Mr. Webster.*) I merely do not wish it to be lost sight of.

(*Chairman.*) Was that the day upon which he took the samples?

(*Mr. Webster.*) It was the day upon which he spoke of a quantity of rain having fallen to the extent of one-third of an inch in 9½ hours; and that, although they had only two sewers out of three at work, no overflow, as he stated, occurred at any part of the system. I have information from the pier-master at Blackfriars that there was an overflow during the greater part of the day.

(*Chairman.*) I really cannot see the relevancy of it

27 June 1883.

to this inquiry. What we really are engaged in inquiring about now, and I think I speak with the approbation of my brother Commissioners, is as to the condition of the river from Greenwich to below Greenhithe.

(*Mr. Webster.*) I am quite prepared for that; but I submit that if it be taken as the datum upon which the condition of the river below is to be ascertained; that upon a particular day when there was a great pressure of rain there was no overflow; and if Mr. Law has argued upon that basis,——

(*Chairman.*) Would you allow me. The quantity of sewage discharge is known; it is agreed; the discharging capacity of the sewers is known. If upon this particular day, in spite of these two known things which show that the Blackfriars sewer ought not to have discharged, it still did discharge, that indicates that there was something wrong or irregular with respect to this particular sewer.

(*Mr. Webster.*) Your Lordship does not quite follow me. I am not the least anxious to enter into an argument upon it; but if my learned friend, Mr. Bidder, should afterwards refer to this discharging capacity—

(*Chairman.*) If Mr. Bidder should say so, I, as at present advised, should make the same remark to him as I now make to you.

(*Sir John Coode.*) But Mr. Law is not here.

(*Chairman.*) Though I do not, if I may say so, care for Mr. Law, I care for what he proves.

(*Mr. Michael.*) I will send for Sir Joseph Bazalgette, and he shall give the information. I will undertake that it shall be given.

Mr. Henry Clifton Sorby, LL.D., F.R.S, called again; cross-examined by Mr. Webster.

*Mr. H. C. Sorby, LL.D., F.R.S.*

16,682. With regard to this very learned book which you have written, I will tell you at once I have not mastered a quarter of it, and therefore I will only ask you a few questions in cross-examination. In the first place, will you tell me what you include under the head of algæ?—There are a vast number of divisions of algæ but those to which I have specially referred are the confervoid algæ, the desmid algæ, and the diatoms.

16,683. Are those three classes sufficient in the percentage of the algæ to base your calculations upon?—Are you referring to the tables that I give at page 13?

16,684. I am referring to the blue line of algæ which appears upon diagram No. 1. In order that I may follow you, I should be glad if you would give me the generic names of the classes of algæ that you have taken?—I have united together the confervoid algæ and the desmid algæ and the diatoms.

16,685. And those may be taken to be what you have included under the name of "algæ"?—That blue line refers only to the relative amount.

16,686. But, in determining the relative amount, it refers to these three things that you have added together?—It does.

16,687. I have examined your tables to a certain extent. Am I right in saying that, except in certain cases, the proportion of road detritus to fæcal matter is about 4 to 1?—It varies in different parts. I allude to it in one particular case at one particular part of the year. I took it at Erith, but it varies at particular times of the year and according to circumstances.

16,688. Take page 17, where you say, "Taking "then as our standard for reference 100 muscle fragments and 100 oat hairs and spirals, we have as "follows for this mud at Erith: 1·08 per cent. of "the detritus of fæces in sewage and 4·11 per cent. "of the road drift." That is approximately 4 to 1?—That applies to the month when I was at Erith, and nothing more.

16,689. What I want o know is this,—Given any sample of water in which there is polluting matter, have you been able to determine what is the proportion of pollution due to road detritus as distinguished from sewage matter?—I think so.

16,690. What do you say is the general proportion?—In some cases there is a considerably larger proportion of detritus of human fæces to road drift; in other cases there is no trace whatever of detritus of fœces, and nothing but road drift. It is simply a question of time and of circumstances.

16,691. I have not made my question clear. In the sewage as discharged at the outfall, what do you take as the proportion of road detritus to sewage?—The calculations you are referring to refer to four per cent. and one per cent. of the amount which is present in the average sewage.

16,692. I may take it, may I not, that taking that to be something which represents approximately sewage mud, it would be 4 to 1?—At Erith at that time; at other parts of the river it differs enormously.

16,693. But I am taking Erith as representing something which is near the outfall. Now to pass to another matter (and I will take you as nearly as I can in the order of your pages). I will call your attention to page 5. The whole value of your theory depends upon the value of your quantitative process, does it not?—I will not say the whole, but to a large extent.

16,694. I do not say entirely, but do you substantially depend upon that?—I am willing to put it upon that basis.

16,695. Now I will call your attention to a statement made at the bottom of page 5. You say, speaking of certain things, "They often show the "microscopical structure of muscle to such marvellous perfection that they could not be confounded "with any other objects. Many of the fragments, "however, have no such form or structure as to "*completely prove* that they are derived from muscle, "though there can be no reasonable doubt. In "estimating the number in an unit volume of "material, *all* the former are counted, but *only half* "the latter. In other words *double value* is accorded "to those cases about which there can be no sort of "doubt." I want to understand how you got at this theory of counting only one half?—I thought it was the most accurate and the fairest way of dealing with the subject. Supposing you are studying this material derived from human fæces, there are a certain number about which you cannot doubt for a moment. About others there is no reasonable doubt, but there is no absolute proof. To leave those out altogether would be wrong, and to take them in altogether would be wrong; so I thought the fairest system would be to give half value to those. The same system has been carried out through the whole of my researches; so I think it is upon the whole the fairest and the most accurate way of dealing with it.

16,696. Now I will ask you this,—If you had followed the same system throughout, as you are only dealing with relative proportions, the relative proportions would probably have been the same?—I have no doubt about it.

16,697. Except what you have told us, have you any ground for taking the one-half?—I have no special reason, except that, if you were to take the whole, you would certainly be wrong, and if you had taken none you would also certainly be wrong.

16,698. So you thought that the fairest mode was to take half?—Yes; but, if you take one-third and apply it uniformly throughout the observations, you will get a very fair result.

16,699. It is upon the principle of getting the fairest approximation that you roughly can?—It is. As I have said, this method is to a large extent novel, and one must do the best one can; and I think I have adopted the best and, upon the whole, the fairest and most satisfactory way.

16,700. When you speak of its being "novel," a similar system has been used for counting the corpuscles in blood, has it not?—Yes, a similar principle.

16,701. Now, how do you get your figures for these minute things upon page 13?—When one has done the same operation a great many times, he is pretty well versed in it. The method I have adopted is, that I have the mud in a small test tube, with about two to three times its volume of water. Then I have a pipette of a different kind to what is usually employed. It is a glass tube open throughout, and of even diameter throughout, and with a small india-rubber ball at the top. The mud settles at the bottom, and the most important thing is to take out a certain portion of a perfectly uniform character. Then I put the pipette into the water, and take up a small portion. By this method I scarcely ever fail to get a proper amount upon the glass, and I get a perfectly uniform spread of material. If I get too much, I give the thin glass cover a slight squeeze and press a little out. Six observations of that sort are made, and if in one case I find I have taken too small a quantity, I take another dip and get a little more the next time, so that, upon the whole, I get a fair sample.

16,702. But how do you get at the $\frac{1}{20}$th of a grain?—I find that, by taking a considerable number of specimens of that kind, and washing the material off and weighing it. The quantity that I have adopted for the unit of observation weighs the $\frac{1}{20}$th of a grain.

16,703. It depends upon the accuracy of your taking up your given quantity each time?—No doubt it depends upon the skill of the operator.

16,704. The quantity you take up is divided into a number of fields, and then examined under the microscope; is that so?—No. You sweep over the whole. If that (*indicating a small surface*) were the entire surface of the glass, I have a mechanical stage, and I sweep up and down, so that I can look over the whole without missing any part of it.

16,705. Your quantity would depend upon the thickness of the field you were examining, would it not?—You can judge from the spread of the material. It depends partly upon the thickness and partly upon the closeness of the material; but by the large practice I have had, I think the results show that this method can be carried out with an abundant accuracy for the purpose of this inquiry.

16,706. You will agree with me, that I have not put it incorrectly, upon the instructions given to me, that the accuracy of this quantitative analysis would depend upon the closeness of the particles and the thickness of the field?—Yes, no doubt.

16,707. Would not a grain of sand separate the two glass surfaces so far as quite to upset the thickness of the field?—All the large grains are carefully washed away as I have described, because the large grains of sand would undoubtedly interfere with accuracy of observation.

16,708. All your experiments depends upon the fact that the grains of sand are carefully washed away?—Very often I find that the grains of sand have escaped, and in that case I should put the experiments aside; or if it were any other small object I should press the surface down I may confess that the success of the method does depend upon the skill of the operator. If you were to give anyone totally inexperienced with the method that observation to make, he would make, in nine times out of ten, a mistake. I used to make a great many blunders, but by practice I have been able to do it in a manner which, I may say, now astonishes myself.

16,709. Now will you look at page 7, where you give the ultimate per-centage at 13. Do you use that per-centage afterwards in your tables?—No, it is not used at all; it is merely to show that you may express the character of the road drift in these terms; it is not used at all afterwards.

16,710. I want to get clearly from you that you do not use in the tables the per-centage thereby arrived at?—No; that is only to show that the relative number of spiral vessels and hairs of oats, upon the average, corresponds with that in the excrement of horses; it is only showing the relation between the road drift and the excrement of horses.

16,711. Because I call attention to the fact that it would be scarcely a correct method of arriving at the average, to add these numbers up and divide them?—Yes, it would; because I show that in the excrement of horses there are 13 per cent. of the spiral vessels and hairs of oats, and it is the same in the road drift.

16,712. Now what year does "Barking, May 4th and 26th," upon page 9, refer to?—The whole of that table relates to 1882.

16,713. All that table?—All the specimens described in this Report were specimens collected last year.

16,714. You mean 1882?—Yes, all those specimens were supplied to me by Mr. Dibdin for the Metropolitan Board of Works. I had nothing to do with the collecting of those specimens.

16,715. It is suggested to me that that cannot be so with regard to the specimens collected in March?—It is so, because I examined them in March, and I can guarantee they were not collected afterwards.

16,716. Will you turn, if you please, to diagram No. 5, showing the relative amounts of detritus of fæces, and of the residue of horse excrements in equal quantities of water; the red line is the fæces, and the blue line the horse excrement?—Yes.

16,717. According to this diagram, if I rightly understand it, there is more of fæces and excrement at London Bridge than there is at Barking, and just below the outfall at Erith?—Yes, per gallon of water.

16,718. Is there more in the sewage itself? I do not understand it; do you say the sewage which is turned out at Barking has more or less in it per gallon than the water into which it is turned?—A very great deal more; that is shown in another diagram. That diagram refers to the mid-stream, and not to the sewage flow.

16,719. Will you just explain to me. Is this diagram to show that the water at London Bridge is worse than the water at Barking Creek, when the sewage is turned into it, or not?—I think so, decidedly, per gallon.

16,720. If it is per gallon it is per river, I should have thought.

(*Chairman.*) No, because there are more gallons at Erith.

(*Mr. Webster.*) Suppose there are 10,000 gallons at London Bridge, and 10,000,000 gallons at Erith, if it is worse per gallon I should be justified in thinking that it is worse per river.

(*Chairman.*) No, I do not think so. Suppose there are half a dozen persons with two sixpences upon them, and there are two persons with six sixpences upon them, which of them has got the most sixpences upon them?

16,721. (*Mr. Webster to the witness.*) Gallon per gallon, you say the river is worse at London Bridge than it is at Erith?—I do say so. The very first day I devoted to this subject I came to that conclusion, and the more I worked at it the more the facts justified me in thinking so.

16,722. That, you think, is the result which the diagram shows?—That applies more especially to the residue of road detritus, and that, no doubt, is to a large extent due to the fact that this is material that does not decompose, and that has been gradually increasing down the river, while the river has not increased in magnitude in proportion.

16,723. That table is based, is it not, upon the accuracy of this quantitative system?—Quite so.

16,724. Will you kindly turn, if you please, to page 6 for a moment. I want to get this clearly from you. On page 6 you refer to the effect of spirals as being developed from green vegetable food, and the other matters you referred to; have you read Dr. Tidy's evidence upon that head?—Yes, I have.

16,725. I think you say you agree with him as to

*Mr. H. C. Sorby, LL.D., F.R.S.*

27 June 1883.

what spirals show, do you not?—Yes; only you have a large number of spiral vessels in the road drift which have come from the excrements of horses.

16,726. Then you say on page 12, "Another most "important constituent of the mud all down the "river is the excrements of minute crustaceans and "other small animals. The nature of these admits of "no sort of doubt, since they can be seen *inside* the "small transparent creatures, and are rapidly voided "when the minute shrimps, which occasionally occur "in such vast numbers in the lower part of the river, "are kept for a short time in water. In the upper "part of the river, where the water is fresh, the "common forms are Cyclops, Cypris, and Daphne. "Having kept tame shrimps for months which fed "out of my hand, I have no sort of doubt as to their "carnivorous habits, and do not hesitate to conclude "that the whole class feeds on the muscle fragments "suspended in the river water, and on the finer "grained mud containing much organic matter." Do not you know that a large number of these same animals, or whatever you call them, have been found to abound in water in which there is neither muscle nor sewage matter?—That is quite probable; they occur in great numbers in the sea.

16,727. And not only there, but in river streams in which there is neither sewage matter nor muscle?—That is so.

16,728. I do not know how you can base any argument to the effect that these are principally carnivorous animals which feed upon muscle fragments?—Crustaceans are most voracious; they will eat almost anything that can be looked upon as of animal nature; they eat one another, and they eat anything they can get.

16,729. If they only eat one another, they would come to an end very quickly?—They will eat any dead one as soon as they can get him.

16,730. If it be the fact that these animals are found in as large proportion in streams which have not got muscle in them, and have not got sewage matter in them, is your deduction quite sound?

16,731. (*Chairman.*) Did you say that? Is it the case that they are found in rivers where there is no sewage matter in as large a proportion as in sewage rivers?—I am not prepared to say that, because I am not aware that anyone has hitherto adopted the quantitative method with respect to them. As far as I have been able to examine at other times of the year, the circumstances being the same, there are not the same quantity in the pure water as in the impure.

16,732. (*Mr. Webster.*) What you say here is that you "have no doubt as to their carnivorous habits, "and do not hesitate to conclude that the whole class "feeds on the muscle fragments suspended in the "river water"?—I do not mean to say that they do not eat anything else, but that they do eat the muscular fragments suspended in the river water. As soon as I got to Greenhithe I collected a number of those Cyclops, and I thought it was very important to ascertain whether they would eat this material; and having got some of them in a glass beaker, I added some portions of human excrement and they immediately attacked it. I have kept them alive for six weeks, and there they are as healthy and hearty as they were to begin with, and they have nothing else to eat.

16,733. But I should think there was very good vegetable matter in human excrement to eat; I do not see why it follows that they eat only muscle?—But there is no evidence that crustaceans eat vegetable matter.

16,734. (*Dr. de Chaumont.*) Is it not the fact that entomostraca are present in considerable quantity in well water?—I think it is quite possible, and in that case my impression is that they would feed on any polygastric animalculæ they could get hold of. All I contend is, that these entomostraca must eat a large quantity of this material; they will eat it, as I know. The number of their excrements down the river is enormous, and that must be accounted for by something they have eaten.

16,735. (*Sir John Coode.*) Would you consider the excrements of the entomostraca are innocuous?—That I am not prepared to say.

16,736. I ask the question because it might be only a change of size in the excreta?—With this qualification, an animal eats a certain amount of food; the amount of the excrement is not equal to the amount of food consumed. For instance, we eat a large quantity of food, but nobody imagines for a moment that the whole of that passes out in our excrement. A certain portion does pass out, but by the life process a large amount is absolutely consumed and oxidized; the rest passes in the excrement.

16,737. (*Mr. Webster.*) A member of the Commission has put questions upon that point which render any further examination by me upon it unnecessary. Now I will call attention to Table 5, page 13. "Barking Creek means 21,000 algæ; sewage flow "after 1½ miles, August 11th, 22,000." Is that 1½ miles below Barking?—Yes, a number of specimens were collected at half a mile, a mile, and a mile and a half.

16,738. But does the 1½ miles mean below Barking?—Yes, in the line of the sewage flow.

16,739. Did you take it below Crossness as well?—No, those specimens were not collected for this special purpose but for another purpose.

16,740. Where do the algæ come from, out of the sewage?—Certainly not; there are very few in the sewage.

16,741. This is per $\frac{1}{20}$th of a grain per unit?—Yes.

16,742. To what do you attribute the enormous increase of algæ at Barking as distinguished from Woolwich, and in the 1½ miles as distinguished from Woolwich?—Diagram No. 1 will show that.

16,743. If this quantitative analysis is reliable, and you say they did not come out of the sewage, where can they have come from to have increased in this extraordinary manner between Woolwich and Barking?—It is an enormously rapid growth. Those that are met with at London Bridge are small, and as you get down the river you find them greatly increase in size and in number. I was, myself, astonished at the facts, but I cannot doubt the facts for a moment, because they are so patent.

16,744. But this is number and not size?

(*Chairman.*) Would you allow me to suggest that the difference amounts to 5 per cent.?

(*Mr. Webster.*) Not between the 9,000 and the 22,000. I am taking it as between Woolwich and Barking first.

(*Witness.*) It may partly be due to the fact that they are a species which live best in brackish water.

(*Chairman.*) It may be that they find more food.

(*Witness.*) I think it may be partly due to the fact that those are algæ and diatoms, which live better in brackish water. They are of a kind which do not occur higher up the river except in small quantity, and this species that are met with at London Bridge are small; they appear not to be growing in favourable conditions. At the outfalls they increase in size and in number, and when you get further down still, they get into too salt water conditions to enable them to develop. My impression is, that the carbonic acid in the river water near the outfalls enables them to grow more rapidly than they can do in pure water; if there were no carbonic acid they would not grow at all.

16,745. (*Mr. Webster.*) But where does the carbonic acid come from that is down there?—If you have sewage thrown into the river, and oxidation takes place, the carbonic acid must be produced.

16,746. You say the oxidation of the sewage frees the carbonic acid, and that enables these creatures to multiply and grow?—It must. I take it that the greater number is the test of the fact and of the partial saltness of the water.

16,747. I want to call attention to page 18 of your report with regard to the term "Sewage flow 1½ miles below outfall"; is that below Barking?—Yes.

16,748. Has it not been observed below Crossness?

—No; these were collected for a particular purpose apart from this.

16,749. Nowhere in your tables do you seem to have regarded the Crossness outfall; is that a mere accident?—The Crossness outfall has been studied quite as much as the Barking outfall.

16,750. But I do not find that any of these tables, either No. 5 or No. 6 or No. 7, deals with the sewage below Crossness anywhere?—We collected that sewage at Barking because the Barking sewage is stronger; it is a richer and a stronger sewage than at Crossness.

16,751. You mean the sewage which comes out of the northern outfall?—Yes; we thought it best to take the very worst we could get, but Crossness has not been omitted at all.

16,752. Now I will take page 19, "Teddington above weir." I want to call your attention to a remarkable fact that Teddington above weir is shown to contain 32·0 of oat hairs and 28·0 muscle fibres. Where were those taken?—I do not know; they were not collected by myself. I am informed they were collected in mid-stream immediately above the weir.

16,753. Immediately below the weir it sinks to 10 of muscle fibres directly?—Because it is diluted with a larger amount of mineral matter; there was a larger amount of mud per gallon, that mud being stirred up by the fall over the weir, I think.

16,754. Is the result of this Table 8 to show that the water at Teddington is worse than the water at Barking Creek?—The mud itself is worse, but the water itself is not.

16,755. This is suspended in the water, you know?—No; that is the amount in an equal weight of mud.

16,756. I will call your attention to the heading "Showing the number of muscle fibres, &c., &c., in "various samples of the mud suspended near the "surface in mid-stream"; that is the mud floating in the water or stirred up in the water?—Yes, and those are per-centages by weight of the mud not of the water. If you will refer to Table 13 you will see the whole thing plainly; you will see that the total amount per gallon of water is very small. I must confess I was exceedingly astonished to find that amount of human fæces in the water at that part, but I had only one specimen for examination.

16,757. What I put to you is this: do you think that was an examination upon which you could rely for the water above Teddington Weir, when you found such a result as you did on the 28th of August, that is to say, contrasting Teddington with Barking?—The reason such a few specimens were collected there was that it was not thought necessary for the purpose of the inquiry, and it was too late to collect others when the importance of it was known.

16,758. Do you think that could be relied upon?—I think sometimes it might be twice as bad and sometimes not so bad.

16,759. If you will observe the oat hairs they do not seem to corroborate you at all?—There is no definite connexion between the two.

16,760. But when I asked you how it fell so much immediately below the weir, you said that was due to so much more mud being stirred up by the water tumbling over the weir. If that were so, that would apply as much to the oat hairs as to the muscle fibres, would it not?—I quite admit that to some extent; but, considering there were only two specimens taken, such a thing might easily happen. And, again, you must bear in mind that there is a possibility that a certain portion of muscle fibre might be destroyed; the muscle fibre is a materal which would be much more readily destroyed than the oat hairs.

16,761. We will look at the general conclusion in a minute or two. I will first call your attention to page 30, where you say, "This amount of material "brought back varies much according to the state of "the tide. Dividing my observations into two periods, "one of slack and the other of strong tide, we have "as follows: from August 12th to 16th and 22nd to "28th inclusive, being periods of weak tides, 66 per "cent. brought back; and from August 17th to 21st "and 29th to September 3rd, being periods of strong "tides, 24 per cent. brought back." Is it not the fact that during both those earlier periods the tides were making, and that during both the latter periods the tides were taking off?—No; those are divided into periods equally on each side of the minimum tide and the maximum tide, as far as I could it.

16,762. We can get it from a tide table?—The whole of the data during that period are given on page 29.

16,763. Do you know the difference between the spring tides making up and taking off?—I certainly do, seeing that I live on the water five months in the year.

16,764. I am told that the first two periods, when the larger quantity is brought back, are periods when the flood tides were making; that is to say, the flood tides were getting stronger every tide, and that in the other two periods the flood tides were taking off—going down to the neap?—I do not fairly understand you. They are taken at even times. From August 12th to the 16th you will find that is the period of the weak tide.

16,765. They were making then?—Yes.

16,766. And then in the second period, from the 22nd to the 28th, they were making, were they not?—No. On the 22nd 14·6 was the range, and it came on the 24th to 13·7.

(*Sir John Coode.*) From the 13th to the 22nd of August they were falling, and from the 22nd to the 28th they were rising.

16,767. (*Mr. Webster.*) It follows from that, that the balance in both those cases is in favour of taking off, as they were making two days and taking off four days. Now, upon the last of the two periods, from August 17th to the 21st, and from the 29th August to the 3rd September, were they making?—They were the periods of strong tide.

16,768–78. Were not they taking off at that time?—They were partly taking off; they were first increasing and then taking off.

(*Sir John Coode.*) It is quite clear from the table.

(*Witness.*) This diagram, No. 10, shows it perfectly well; that shows the range of the tide, and you find the maximum point exactly corresponds with the maximum range of the tide; the secondary maximum is due to the rainfall which is marked upon the table.

16,779. (*Mr. Webster.*) Now I want to call your attention to the results shown upon your tables on pages 28 and 29, taking especially the observations of the 21st of August. I call your attention to the table upon page 29, when there was an impulse or extra quantity of 601,000,000 gallons?—Those results are not from my own observations.

16,780. But, assuming them to be accurate, and you have put them in, it is the fact, is it not, that contemporaneously with the increase of water upon the 21st, there was an increase of solid matter in the sewage at Erith? I call your attention to your own deduction upon page 28, where you say, "The "maximum of residue carried down on September 2nd "is a day later than the maximum tide, and appears "to have been caused by the extra rainfall on "September 1st?"—Yes.

16,781. The deduction you draw is that the effect of the impulse of the increased upland water is to increase the quantity of solid matter which appears in the sewage?—It is the solid matter carried down the river.

16,782. Then I will say the solid matter at Erith in 24 hours?—All I can say is this, that there is a rainfall taking place there. You will find that at that time there is a considerable rainfall at Erith, and the rain falling upon the mud banks washes the mud into the river.

16,783. Now I will call your attention to this: the secondary maximum on August 24th clearly corresponds with the well marked maximum of upland water upon that day.

(*Chairman.*) I thought the best thing I could do to

*Mr. H. C. Sorby, LL.D., F.R.S.*

27 June 1883.

get at an opinion upon this matter was to look at the general conclusions.

(*To Mr. Webster.*) Do you dispute them?

(*Mr. Webster.*) I do.

(*Chairman.*) Do you dispute the large quantity of the more objectionable constituents removed by minute animals?

(*Mr. Webster.*) Yes.

(*Chairman.*) Do you deny that the minute animals destroy any portion of the sewage?

(*Mr. Webster.*) Not as to "any portion."

(*Chairman.*) Do you deny that a large part is so destroyed?

16,784. (*Mr. Webster.*) I am instructed to ask a question as to that conclusion not being supported by scientific facts. (*To the witness.*) I will ask you to complete your answer?—It is merely that the extra amount of rain that was gauged at Seething Wells does not mean that; it was merely a guide to the amount of rain that was falling in other parts.

16,785. Now I will go to what Lord Bramwell referred to just now, that is, the conclusion stated at the end of the report. In the first conclusion I see you say in effect that the value of the quantitative method depends upon the accuracy of the observer?—It does so; only I would premise, that carried out in the way I have carried it out, it is proved to be accurate by the results I have obtained.

16,786. Now, you say that "a large part of the "more objectionable constituents of sewage are re- "moved in summer by the unobjectionable action of "minute animals." Now, I want you to tell me, as shortly as you can, with the facts you have before you, upon what you base that deduction?—Of course you cannot watch them eating it; it is a matter of inference. But what I contend is this, that when we find, in the winter time, a very few of these excrements as described in this report, compared to what we do in the summer, and at the time when there are very few of those excrements, you find that there is a large amount of debritus of human fæces, that is to say, comparatively large; and when you bear in mind the enormous number of these excrements, especially down the river, and that these excrements represent material which has been consumed; what I contend, I say, is that the large amount of these excrements, and the considerable number of these animals present in the river (which I have proved do feed upon these things), is proof that a large portion of the objectionable constituents of the sewage is so removed.

(*Chairman.*) I suppose the quantity of objectionable matter found in the water and in the mud is ascertainable by analysis and by examination. If a quantity of the sewage is gone it is gone by some means or another; by what means is perfectly immaterial; and this witness comes and corroborates the notion by saying there is something which takes away such and such portions of it.

(*Mr. Webster.*) I quite appreciate the crisp way in which your Lordship puts it; but I object to Dr. Sorby's conclusion, that it is removed in summer by minute animals, and not by being taken out to sea.

(*Chairman.*) But, supposing he is wrong, and that it is taken out to sea, what then; the question is, whether it is gone.

(*Mr. Webster.*) If it is a question of the tide taking it out, one would inquire why the algæ have not disappeared also.

(*Chairman.*) The witness gives *à priori* evidence to show that it would be gone, but the direct evidence is that it is gone.

(*Mr. Michael.*) And, besides, Dr. Sorby does not say that other means are not in operation.

(*Witness.*) As far as the tides are concerned, I have shown in my own tables that 60 per cent. of it is carried away.

(*Chairman to Mr. Webster.*) You cannot fail to have seen what has happened. We leave this room; the evidence given by the witnesses is handed to half a dozen people to pick all the holes that can be picked in it, and they come and instruct you upon it; what can you do except act upon those instructions.

(*Mr. Webster.*) I am perfectly incompetent myself to act in the matter without instructions.

(*Chairman.*) I can quite understand that, but I put it to you that it is immaterial.

16,787, (*Mr. Webster.*) If your Lordship thinks that it is immaterial, I will use my own judgment upon it, and not pursue it further. (*To the witness*). I will only put this one more question to you. Would you kindly tell me whether you have any fact upon which you base your deduction that a large part, I say distinctly "a large part," of the more objectionable constituents are removed in the summer by the unobjectionable action of minute animals?—What I put forward is, that the chemical gentlemen who have given evidence have altogether overlooked this large action; and when we find this enormous amount of excrement which undoubtedly comes from entomostraca, or something of the kind, which do eat these substances, and when you find 6,000 of them in a grain at Erith, that shows the immense number there must be of them, and the work they must do. Of course they are small. When you come to have 6,000 in a grain, you cannot expect them to be very large. A number of the statements made in this report have been substantiated by the experiments I have made lately. I have been following out quantitatively this analysis, showing how many of these things there are per gallon; and we know they rapidly increase, because it is stated that one of these cyclops can in a year, if they all survive, give rise to 4,000,000,000.

17,788. (*Chairman.*) Do you mean one of them does?—I do not say it does; it could, provided they all lived; they will increase to that extent if the conditions are favourable and they have abundance of food. Now those are rapidly growing, and my friend, Dr. Murie, of the Linnean Society, who came to see me at Erith, said, "You will find the number of them much greater later on in the year."

Re-examined by Mr. Michael.

16,789. Would you kindly explain to the Commission the meaning, on page 17, of the 1·08 per cent. and of the 4·11 per cent.; does that mean the constitution of the sewage or of the mud at Erith?—Of the mud at Erith.

Examined by the Commission.

16,790. (*Chairman.*) Is that cyclops visible to the naked eye?—Yes, readily; they are about one-sixteenth of an inch in length, and some are larger considerably; at Crossness you have a greater number of the Daphnes, which are larger than the Cyclops.

16,791. Is that their fæces (*pointing to a diagram*)?—Yes; that is greatly magnified.

16,792. How is it ascertained that they multiply to anything like the extent you mention?—I am not responsible for that, that is merely asserted in a work on crustaceans; but you will see they carry two bags of ova; it is known how long it is from the hatching until they can breed, and then it is only a question of calculation as to how rapidly they breed.

16,793. Then you have seen them feeding, you say?—Yes.

16,794. With the naked eye?—I used a pocket lens.

16,795. (*Dr. de Chaumont.*) You have spoken of the number of these animals in the mud; what becomes of them?—I find the principal source of their death is their being drifted out to where the water is too salt for them; the numbers of deaths depend upon the spring tides; the spring tides bring up more salt

water than is good for them, and they die; but in the meantime, when there is not so much salt water brought up, they live.

16,796. Do the carapaces remain?—Yes; you find the remains of them in the mud, but no doubt they are largely carried down and washed away with the other material.

16,797. (*Sir John Coode.*) If you turn to diagram No. 5, you have told us already that you were struck with the large relative amount of the detritus of human fæces near London Bridge?—Quite so.

16,798. It was very striking; but have you formed any conclusion as to how that large quantity is found in that part of the river?—I think a good deal must come from the shipping; but the difficulty to a large extent disappears when we take into account the large volume of the river further down.

*Mr. H. C. Sorby, LL.D., F.R.S.*

27 June 1883.

16,799. (*Chairman.*) Sir John Coode suggests to me that these creatures devour excrement, but that they leave their own excreta, and that their own excreta may be as noisome as what they devour?—I think it exceedingly probable that their excrement might be objectionable; but at the same time in the life process of the animals a very much larger amount of material would have been consumed than is given off in the excrement.

The witness withdrew.

(*Mr. Michael.*) There are two matters which we promised to put in, namely, extract from Dr. Collingridge affecting the West Ham pumping station at Bow Creek, and a return of the hand and steam dredging licenses from 1863 to 1882. (*The same were delivered in. See Appendices BS. and BT.*)

(*Mr. Beaumont Morice.*) Would you allow me to mention a matter, with regard to the evidence, which I brought forward in the early part of the Commission. Your Lordship knows that, on behalf of the memorialists, I brought forward a number of witnesses in November, when Sir Benson Maxwell was in the chair, and he intimated to me, on behalf of the Commission, that he thought it would be advisable not to call any more witnesses until my case had been seriously contested or attacked by the Metropolitan Board of Works. I have the passage, at page 43 of your Minutes, in which he stated, "I think that the "feeling of the Commission is that you, Mr. Morice, "have started a sufficient *primâ facie* case. If it "should be shown that your witnesses are really "mistaken, or that they are misleading us, we shall "give you the opportunity of calling any further "evidence that you may think necessary." I stated, in consequence of the statement by the Chairman, that I should not trouble the Commission at that time with any further evidence. That being so, I have only to say now, that having heard the evidence brought forward on behalf of the Metropolitan Board of Works, I have, and I beg to mention it to your Lordship, a number of witnesses, residents and others in Erith, whom I wish formally to tender on behalf of the memorialists and the Local Board of Erith, in order to show that the statements which have been made on behalf of the Metropolitan Board of Works have no foundation.

(*Chairman.*) I think Sir Peter Benson Maxwell's view was in conformity with one which I had mentioned.

(*Mr. Beaumont Morice.*) Yes, your Lordship did hint it previously.

(*Chairman.*) It has been familiar to counsel in cases of rights of way, and things of that description; that you have, say, 20 people, who will come and give you particular evidence, and it is quite possible that you would find 20 more who would come and do the same thing on the other side; that is to say, there would be 20 people who would give you a different character of evidence, showing that their passage had been interrupted, or that they had not exercised the right. What you may call the two twenties show the case upon either side as much as though you were to call two forties. To my mind, therefore, I cannot help thinking that it is no use duplicating the evidence.

(*Mr. Webster.*) My learned friend Mr. Beaumont Morice's point is, that there having been a general statement as to facts, there has been certain evidence given by the Board not upon the question of theory, but upon the question of fact; and if your Lordship thought that the evidence of the Erith witnesses was discredited at all by the evidence upon the question of fact, my learned friend would like to tender those further witnesses.

(*Chairman.*) The question of fact is the question of nuisance, and we have had the evidence of witnesses of undeniable and unimpeachable authority as to the subject of the nuisance. We have had the evidence of Captain Burstal as to the nuisance at Woolwich, that sometimes the smell was intolerable.

(*Mr. Beaumont Morice.*) I fully felt the force of your Lordship's suggestion with regard to the undesirability of calling a great many witnesses at the time to repeat what others had said; but upon the question of fact, with regard to the nuisance, it is a feeling which is so widespread, that it is a matter of some difficulty to limit the number of witnesses that one could bring before your Lordship.

(*Chairman.*) I suppose you could occupy another month at it.

(*Mr. Beaumont Morice.*) I could certainly bring forward a number of witnesses, including residents.

(*Chairman.*) The best way would be for us to keep this matter over after the case for the defence is concluded, and if we think it right that you should call other witnesses, we will let you know before we next meet.

(*Mr. Webster.*) May I beg to say that if your Lordship and the Commission will give us a fortnight it would be a great convenience. I cannot help your Lordship much in this matter, but I will help you as much as I can.

(*Chairman.*) I do not agree with that. I think the assistance of counsel will be of very great use to us.

Mr. Hugh Herbert Mason called; examined by Mr. Norman Bazalgette.

16,800. You live at East Street, Barking, and you are a member of the Royal College of Surgeons, and a licentiate of the Society of Apothecaries, and holder of Sanitary Science certificate, Cambridge?—Yes.

16,801. Have you, since the formation of the East Ham Local Board in 1877, occupied the position of Medical Officer of Health for East Ham?—Yes.

16,802. What does the district of East Ham include?—The parish of East Ham includes a portion of the town of North Woolwich, and a district extending back for about three miles.

16,803. (*Chairman.*) Does your district go to the river?—Yes, it goes to the river.

16,804. (*Mr. Norman Bazalgette.*) I think it includes that portion of North Woolwich which is not in the county of Kent?—Yes, it does.

*Mr. H. H. Mason.*

16,805. First of all, what do you say as to the health of the whole district, generally?—It is about the average of England.

16,806. Do you find any distinction between the health of that part which immediately adjoins the river and the rest of the district?—I find no distinction.

16,807. (*Chairman.*) Your district is above the outfall, is it not?—It is just above the outfall.

16,808. Is the outfall within it?—No, it is just outside.

16,809. (*Mr. Norman Bazalgette.*) Is your district

*Mr. H. H. Mason.*

27 June 1883.

specially subject to zymotic or other diseases, which might be attributed to emanations from the river?—No.

16,810. Where does your practice extend with regard to Barking Creek?—On both sides of it.

16,811. To its mouth?—Yes.

16,812. (*Chairman.*) Do you say you are upon both sides of Barking Creek?—Yes; my official district is only on the east side of Barking Creek, but I reside on the other side of it.

16,813. (*Mr. Norman Bazalgette.*) Your private practice is in a different area from your official practice?—Yes, it is.

16,814. At the mouth of the creek there are, I believe, 50 cottages, inhabited by the employés of Lawes' chemical works?—Yes, there are.

16,815. I believe those employés have a club, to which you are the doctor?—Yes, they have.

16,816. I presume those men are principally employed upon the banks of the river?—They are entirely.

16,817. What population do those cottages accommodate?—About 200 to 250.

16,818. What do you say as to their health?—It is about the average.

16,819. Do you find zymotic diseases have been more prevalent amongst them than in the rest of your neighbourhood?—No.

16,820. Have you met with any typhoid fever amongst them?—No, I have never seen typhoid fever there.

16,821. I believe in 1881 there was an epidemic of scarlet fever in East Ham?—Yes, there was.

16,822. Did that epidemic extend more beyond the district bordering upon the river than in other parts of the district?—No.

16,823. Have you met with any diphtheria at the cottages?—No.

16,824. Have you met with any illnesses which you could attribute generally to emanations from the river?—No.

16,825. Could they have occurred without your knowing of them?—No, they could not.

16,826. Just to localise Lawes' Chemical Works more nearly; they are exactly opposite the outfall, are they not?—They are about 300 yards below.

16,827. Referring to the cottages, would you say, upon the whole, they are as healthy as the cottages in other places?—They are quite as healthy.

16,828. Barking Creek is tidal as far as Ilford, is it not?—Yes.

16,829. What class of population have you living upon each side of the creek?—It is cottage property.

16,830. Are they of a low class or a high class of population?—A low class of labouring population.

16,831. Do you find they are more or less healthy than people of a similar class living in similar places?—They are not more unhealthy; they are much about the same.

16,832. Have you been able, with regard to Barking Creek, to trace any illnesses there to emanations from the creek?—No.

16,833. Have you ever noticed any smell from the sewage in the river?—I have not noticed any smell at Barking nor at East Ham.

16,834. Have you noticed smells from other sources?—Yes, we have various smells from factories in that neighbourhood.

16,835. (*Chairman.*) Your answer imported rather that you had smelt the river?—By Lawes' factory, close to the outfall, of course you can smell it there when the sewage is coming out.

16,836. That is to say, at Lawes' factory?—Yes, when you are close to the outfall, but not at Barking.

16,837. Have you ever noticed the water at Barking at high water to see whether it indicated the presence of sewage?—I have never noticed any such indication.

16,838. (*Mr. Norman Bazalgette.*) Do you remember upon the night of the "Princess Alice" accident a number of bodies being brought ashore at Lawes' works?—Yes.

16,839. Were you there at the time?—I was there about an hour afterwards.

16,840. Did you see the bodies as they were brought ashore?—I saw a number of them.

16,841. Did you observe anything unusual about them?—No, I did not.

16,842. Had you in the course of your practice seen drowned bodies previously to having seen those?—Yes.

16,843. Did these present a different appearance from bodies which you had seen upon other occasions?—No.

16,844. (*Chairman.*) Did their clothes look different from the clothes in the ordinary way upon drowned people?—I did not notice anything different.

16,845. (*Mr. Norman Bazalgette.*) I believe you know that a certain number who were brought ashore upon that occasion recovered?—Yes, I do.

16,846. Can you tell us from your experience as a doctor what they were apparently suffering from; whether it was from the effects of immersion or from anything else?—They were suffering from the immersion or accident.

16,847. How many did you see of them?—I saw about 30.

16,848. (*Chairman.*) Who recovered?—They were landed alive at the creek.

(*Mr. Norman Bazalgette.*) And they seemed to be suffering only from the effects of immersion?

(*Chairman.*) I do not see what else they could have been suffering from, because the fish are suffocated from the want of oxygen, but the human beings were not suffocated in that way.

16,849. (*Mr. Norman Bazalgette.*) Where they apparently suffering from sewage poisoning?—No.

16,850. (*Chairman.*) Did you ever see any symptoms of sewage poisoning in anyone under those circumstances?—No.

16,851. What sewage poisoning have you seen?—I have seen zymotic diseases caused by sewer gas, and I have seen poisoning by sulphuretted hydrogen.

16,852. Would that produce sudden death?—No, a comatose condition previous to death or recovery.

16,853. But it would be within a few hours?—Yes.

Cross-examined by Mr. Beaumont Morice.

16,854. How close to the river do you live?—I live about a mile and a half from the Thames.

16,855. And your district extends along the river, does it not?—Yes.

16,856. What is the number of persons you have in your district?—Do you refer to East Ham?

16,857. Yes?—9,000.

16,858. You say you have not had much zymotic disease?—Not much.

16,859. Did you have an outbreak in 1872?—I was not in the district in 1872.

16,860. Up to how far back do you go?—1874.

16,861. In 1875, do you remember an outbreak then in East Ham?—There was some scarlet fever about that year.

16,862. Was there much?—I cannot give you the details, but I remember there was a good deal of scarlet fever about then.

16,863. (*Chairman.*) In what part of East Ham was that?—All over the district. I knew nothing of the river portion at that time.

16,864. (*Mr. Beaumont Morice.*) Within what distance from the river was this outbreak?—The scarlet fever I saw was all in the upper part of the district.

16,865. How far was that from the river?—The nearest portion I knew anything of was about half a mile from the river.

16,866. (*Chairman.*) Did you hear that that extended to the river?—It would naturally.

16,867. (*Mr. Beaumont Morice.*) You did not know anything about it at that time?—No.

16,868. But it might have been there?—It might have been there.

16,869. Was there any outbreak in Barking town in 1875?—That was at the same time; the epidemic extended over the whole of the district.

16,870. May I take it that there was a very high zymotic death rate in Barking town at the time?—Yes, there was in the town.

16,871. (*Chairman.*) Was it confined to the town?—No, it extended over the whole district of West Ham and into the country.

16,872. Do you know where it first appeared?—I think it came down to Barking from London, if I remember rightly.

(*Chairman.*) I have lived for nearly 22 years in a very sparsely populated part of Kent, where we have no sewage happily, at least no public sewage; each gets rid of his own as best he can, and, upon my word, I think I hear every three or four years of an outbreak of scarlet fever.

(*Mr. Beaumont Morice.*) It differs in degree, I think.

(*Chairman.*) I believe it is amongst children principally, and that they do not die of it very much, but still it exists.

16,873. (*Mr. Beaumont Morice to the witness.*) I was putting to you the high death rate; now do you remember another outbreak in Barking Town in 1879?—There was an outbreak about that time, but I thought it was rather later than that.

16,874. The zymotic death rate was high in 1879 and 1880; may I take both years?—Yes, you may take both years.

16,875. Do you remember what particular diseases were prevalent then?—Scarlet fever and diarrhœa.

16,876. Did that extend to East Ham as well?—It extended to East Ham as well.

16,877. Did you have any outbreak at all last year?—No.

16,878. I may take it that a large portion of your district is from half a mile to a mile from the river; is that so?—The greater portion of it is much more than that.

16,879. But a large portion of it is about that?—50 of those houses are close to the river; the rest are a mile away or so.

16,880. You mentioned about the smell at Lawes' factory; do you go near the river in the course of your duties, except in that particular part?—Not very often.

16,881. Have you been able to distinguish the smell of the sewage from other smells?—Yes, I have once or twice; it is not a thing I have paid much attention to.

16,882. But, residing in the district, would you be able, if you smelt the sewage, to distinguish it from other smells?—I think so.

16,883. With regard to those bodies which came ashore from the "Princess Alice," you say happily 30 persons recovered; how soon after the accident did you see them?—A little over an hour; perhaps an hour and a quarter.

16,884. They had been at once taken out, and brought over?—Yes.

16,885. Do you say you have never known or heard of a case of death being caused by sewage in the river?—By drowning in sewage, do you mean?

16,886. I mean death accelerated by being in the sewage of the river?—I do not know of any such case, and I have never seen one.

16,887. May I ask you, as a medical man, whether, if a person were immersed in a river in which sewage were prevalent, it would tend to accelerate his death, that is to say, diminish his chance of recovery. The reason I ask that question is that at the time of the "Princess Alice" accident there was a large amount of medical evidence that death was accelerated in consequence of the sewage fouled in the river. I ask you, as a medical gentleman, what is your opinion?—Death would be more readily induced by drowning in sewage than by drowning in water.

(*Sir John Coode.*) But the question means by drowning in the Thames, and its then condition, not by drowning in sewage.

(*Witness.*) I should not think so; there was no active gas being given off at the time, as far as I know.

16,888. (*Mr. Beaumont Morice.*) You remember the "Princess Alice" inquest, do you remember it was seriously contended then by medical persons that it would have that effect?—Yes.

16,889. (*Chairman.*) Which side called them?—I do not know. I was not present at the inquest.

(*Sir John Coode.*) The friends of the drowned persons produced the evidence.

(*Chairman.*) If the "Princess Alice" people called them to show they were killed by the sewage and not by drowning, that is one thing.

(*Mr. Beaumont Morice.*) No; those witnesses were called by the friends at the latter part of the inquiry.

(*Chairman.*) With what object?

(*Mr. Beaumont Morice.*) To show the state of the river, for one reason.

(*Chairman.*) To make a claim against the Metropolitan Board of Works?

(*Mr. Beaumont Morice.*) I do not know that.

Examined by the Commission.

16,890. (*Chairman.*) You say 30 recovered of those who were rescued?—Yes, they did.

16,891. A great many, unhappily, did not recover, and were killed?—Yes.

16,892. What was the cause of their death; drowning?—There were about 18 bodies brought ashore dead at the works, and two only of those who were landed alive died afterwards; one was the case of the fracture of the breast bone, and one was the case of an old lady who had been immersed in the water some time, and never recovered from the shock.

16,893. Those two people were not drowned properly; but were the other 18 people drowned; drowning, as I understand, is suffocation?—Yes.

16,894. But it differs from other suffocations, I think I am right in saying, in one symptom, viz., that there is always a frothy appearance. I forget whether it is of the mouth or of the lungs?—At the mouth it exudes a little.

16,895. Were those people drowned?—Upon the bodies that I saw, that were landed dead, I noticed the froth about the mouth and nose.

16,896. Then they were drowned?—I believe so.

16,897. Just as much as if they had been immersed in pure water?—I think so.

16,898. It is difficult for you to answer a question as to whether sewage in the water would facilitate drowning; I should think very likely it would in this way, that a man, instead of swimming efficaciously to save himself, might be so affected by the filthy smell that he could not do his best to save himself; but did you see any symptoms to show, except so far as that might be the case, that the sewage in the water had specifically affected the people's lives?—I did not.

16,899. *Mr. Beaumont Morice* (*through the Chairman*). May I ask whether you saw any bodies some considerable time after they had been in the water; that is to say, after this accident?—Yes, I did.

16,900. In what condition were they?—About as you would expect from the length of time after death. I did not notice that they decomposed more rapidly than I have seen to be the case in other bodies which have been drowned.

16,901. Was there any difference between those and what you would find in an ordinary river, a pure river?—Not that I could notice.

*Mr. H. H. Mason.*
27 June 1883.

16,902. (*Chairman.*) Have you seen many drowned persons besides those drowned at the time of the "Princess Alice" accident?—Occasionally I do; three or four in the year perhaps.

16,903. In the river?—Yes, in the river or in the Creek.

16,904. (*Dr. Stevenson.*) In the case of such an accident, would not the existence of sewage in the water rather manifest itself in those who recovered than in those who were drowned?—Yes; I should say so, if there were any deleterious matters given off from the sewage.

16,905. Did you observe any such cases of what I might call retarded recovery?—I did not.

16,906. Does your district abut directly upon the river for the whole of its extent, or does a part of Kent intervene?—There is a part of Kent intervenes in which the outfall is situated.

16,907. That would cut out a large portion of your district from the river, from the Woolwich ferry up to the Creek almost?—Yes.

16,908. Therefore yours is not a riverine district altogether, it does not abut upon the river directly?—Yes, it does, except for this small portion of Kent.

16,909. (*Colonel Ewart.*) With regard to your evidence about sickness at Barking, is Barking a sewered town?—There is a sewer there.

16,910. But are there not a large number of cess-pools there?—There are a good many.

16,911. And there were at the time of the sickness of which you have spoken?—Yes, more than there are now.

16,912. What water supplies Barking?—The Grays works: the chalk water.

16,913. Do the people all, or generally speaking, get their supply from that source?—They nearly all do now, but they did not at that time.

16,914. (*Sir John Coode.*) Are you aware that at the time of the "Princess Alice" disaster a great deal of discussion arose about the extent to which the deaths were caused by reason of the sewage; was your attention directed particularly to the symptoms exhibited by the bodies that were found; I gather that it was?—It was.

16,915. I gather that, though your attention was particularly directed to the subject, you saw no different symptoms from what you would have expected to find in bodies drowned in pure water?—I am clear as to that.

16,916. Are the Beckton Gas Works within your district?—Yes.

16,917. Are the men there healthy, up to the average?—Yes, for the class of men, and the way in which they live.

16,918. You said that the 200 men at Lawes' works were living upon the banks of the river, you did not mean that literally, did you?—The factory is situated upon the bank of the river, or a little way back, and the houses are situated about 20 yards from the river wall.

16,919. How far does the factory extend back?—I should say the extreme point of the factory goes about 150 yards from the river bank.

16,920. Then both the factory and the dwellings are very close, really, to the sewage margin, are they?—Yes, and I ought to say that the population of 200 includes men, women, and children.

The witness withdrew.

(*Mr. Michael.*) That is our case, my Lord.

Adjourned to Monday, 9th July, at half past 12 o'clock.

# FORTY-FIFTH DAY.

## Monday, 9th July 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
JAMES ABERNETHY, Esq., F.R.S.E., Mem. Inst. C.E.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

9 *July* 1883.

(*Mr. Bidder.*) I am told there was some inquiry made at the last meeting of the Commission, and that Sir Joseph Bazalgette was to inform the Commission as to whether there was or was not an overflow upon the 26th of May at the Blackfriars storm overflow, and Sir Joseph Bazalgette has written a letter to Mr. Ward, which perhaps I may read, giving all the information he has in his possession. "I had made "inquiry and found that there was no overflow on the "26th of May last at any of the five storm outlets at "which records are kept, viz., the River Lee, Western "Pumping Station, Deptford Creek, Office Outlet, "and Falcon Brook Outlet, and my assistant stated "that he believed there had been none at any of the "other outlets. I have, however, since ascertained "that there was a discharge at the Fleet storm over-"flow, Blackfriars, on that day for 1½ hours, between "11.30 a.m. and 1 p.m., and again for a short time "after 8 o'clock in the evening."

(*Chairman.*) I can only repeat that I am utterly at a loss to see what bearing it has upon the question; it only shows that there must have been some specialty with that particular overflow.

(*Mr. Bidder.*) Now, my Lord, in addressing the Commission, and undertaking what I confess seems to me to be rather an onerous task in attempting to do anything in the way of summing up this gigantic pile of evidence that you have before you, it seems to me that it would be perfectly hopeless for me, and utterly wearisome and useless for you, if I were to endeavour to analyse that mass of evidence in detail. The question, as I understand it, which the Commission have to consider is, whether the outfalls of the Metropolitan Board of Works cause a nuisance of such a character as to warrant your recommending a change of system, and it seems to me, in discussing that question, that there is a great deal which has been put upon the notes by way of evidence which I may fairly put aside, and which I cannot help thinking the Commission may put aside, as being irrelevant to the real question that you have to determine. For instance, there was a certain amount of evidence as to

sewage being at times let out upon the flood before high water, and floating up above the outlets. I do not deny that that has been done from time to time: you know why. Because of the insufficient reservoir power upon certain occasions when there has been a rainfall; but inasmuch as you also know that plans are already prepared and have been penned up, only pending the resolution at which this Commission may arrive, I think that may also be put aside. I say it is the intention of the Metropolitan Board of Works to execute works there which would prevent its happening in the future. Then I may put aside also, I fancy, the question of any effect produced by the occasional overflows from the storm outlets—in the first place, because their action is rare; it is a very exceptional thing; and although Mr. Baldwin Latham produced a great many reasons to lead you to conclude that they must overflow when any appreciable amount of rain fell, in point of fact, the evidence shows that his conclusions are mistaken. Sir Joseph Bazalgette has given you the records taken at the principal outfalls, which show you that about 20 times in the year these overflows do occur; they are manifestly occurrences of a very exceptional character, and besides that, *ex hypothesi*, when they do occur, that which overflows is not ordinary sewage, but is matter in a very dilute condition. Further than that, the expenditure which would be requisite in order to abolish these overflows would be something gigantic. I think Sir Joseph Bazalgette has put it at 7,000,000*l.* or 8,000,000*l.*, altogether out of the question in proportion to the damage alleged to be done by them. And then, more than that, the removal of the sewage to the Maplin Sands would not get rid of the storm overflows at all. Then, again, I think I may also put aside a great deal of what was given in evidence by Mr. Baldwin Latham as regards what were the views, ideas, and intentions of those who matured this scheme and antecedent schemes some 30 years ago, as to whether at that time they contemplated the population which is now existing in London or not. It does seem to me that Mr. Baldwin Latham is altogether wrong, because Sir Joseph Bazalgette has completely shown that those points which were made by Mr. Baldwin Latham were fully foreseen, discussed, and considered; but whether that was so or not, the question is whether the sewers being where they are and what they are, they are in fact a nuisance. It seems to me, therefore, that that question is irrelevant, and rather partakes of the character of microscopic criticisms which one may fairly and reasonably decline to join issue upon.

Now, coming to the question as to whether there is such a substantial nuisance caused by the sewers of the Board as to warrant this Commission in making a change of system, I think it is very important to notice, in the first place, with the present state of scientific knowledge, that change of system means one thing, and one thing only; that is, carrying the sewage further down the river or else further out to sea. What may be invented in the future, heaven knows, but I think I am justified in saying that nobody at present can point to any mode of dealing with the sewage of such a gigantic city as London in any other way than that of taking it out to sea. Therefore the question narrows itself into leaving the sewers where they are, or recommending that they should be carried somewhere else

(*Chairman.*) I think we ought to tell you that we have not gone into the question of a remedy. We have had no witnesses upon that subject; we have no trustworthy facts before us. The question is, whether it is a nuisance. I have felt myself a difficulty which you will probably feel. You would not deny that there are things it would be desirable to get rid of if it could be done with the wave of a wand. Then the difficulty is to state the extent of the nuisance. We are now dealing with the first question: is there any, and if so what, quantity of nuisance? It is extremely difficult to define it. Is it "very very bad," or only "very bad," or "all bad," or what?

(*Mr. Bidder.*) Or "rather bad"—quite so, my Lord. I do not want to discuss at all the former question. I am quite aware that in the present stage of the Commission you have not entertained the question of an alternative; but I think it bears upon the discussion of the present case to keep in view the fact which I think I am entitled to put forward as a proposition, namely, that having regard to London and London sewage, nobody will venture to say that it can do anything but go either into the river or into the sea; that is to say, supposing the nuisance were ever so bad, you cannot by a wand either abolish the population of London or make them cease to produce sewage; and I venture to say that nobody under the present state of knowledge can point to any other way of getting rid of it. And I refer to that for this reason, because I want to repeat, if you will forgive me doing so, one point to which I drew your attention in my remarks at the outset of the case, and that is this:—to ask you to distinguish between what I call, immediate local effect of the pouring out of the sewage, and its general effect upon the river. When I use the phrase, the "immediate local effect," I mean its effect within a quarter of a mile or half a mile of the place where it is poured into the river, and I make that distinction, because I say it is manifest, however you pour the sewage in, an immediate local effect, whatever it is, must be produced—there is no help for it. Then people may say it would be very much better that the sewage were down at Gravesend or anywhere else; but if it were down below Gravesend, wherever you went, I venture to say it is clear you would produce that immediate local effect, and there is good reason to apprehend, judging from the evidence of the chemists, that it would be worse there rather than better, because there appears to be reason to gather from the evidence that when the proportion of the sea water is larger than it is at the outfalls, the nuisance would be worse than it is.

(*Chairman.*) Has that been stated by the witnesses?

(*Sir John Coode.*) I think it is well recognised.

(*Mr. Bidder.*) I think it is a well recognised fact that the more salt the water into which you pour the sewage the more offensive the result. Now your Lordship sees why I make the distinction between the two classes of effect. Whatever importance is attached to the immediate local effect, it is not to be supposed that by moving the sewage to another place you would get rid of it—you would only move it to another place, and by moving it to another place you would probably make it rather worse than it is at present.

Now it becomes important to notice what one might guess, and what one knows from what one has been told by Sir Joseph Bazalgette, that at the time these outfalls were designed, these very sites at Barking and Crossness were specially selected after a very great deal of anxious consideration, and surveys of the river, by engineers and others, for the very reason that they appeared to be pre-eminently places suitable for such a purpose, because they were places already devoted to stinks and evil odours and manufactories that could not be tolerated in any other neighbourhood; and I think we have it in evidence here that, in point of fact, for very many miles around—anywhere—I should say, up and down the river, it would be difficult to find a place so suitable in that respect—so free from population to be affected by the immediate nuisance, if nuisance it be, as this.

Now, speaking first with regard to that immediate local nuisance or local effect, what does it amount to? Nobody denies, in fact, I presume, the Commission saw for themselves, when they saw the sewage coming out, that that is a nasty offensive black stream, and that stream can be traced by the eye a certain distance, some people say as far as half a mile, others go as far as to say a mile, there is a very nasty smell which you can trace by the nose, but which many of the witnesses I have called before you say confines

9 July 1883.

itself to about 100 or 200 yards; at any rate, as a rule, it is very limited in its area, and though I shall have to discuss evidence which will be of a different bearing presently, I cannot help thinking that the result of it all comes to this—that really the perceptible and immediate effect of the sewage is confined to a very limited area; it may be taken to be from half to three-quarters of a mile from the point of outfall. There has been a great deal of discrepancy in the evidence I know, but fortunately it has not been a discrepancy of evidence like that in running down cases in which your Lordship has had considerable experience, in which there is always, and always must be, a considerable difference of opinion; but here is a case in which your Lordship and the Commission can go for yourselves and judge by the effect upon your own senses what is the effect of the sewage, and whether it is immediate or not.

Now, therefore, I pass from that to go to that which appears to me to be more important, and to the attempt to prove which the great strength of my learned friends has been directed, namely, the great pollution of the river, not only at Crossness and Barking immediately, but for many miles up and down, creating a state of things which is prejudicial to the health of the inhabitants, and prejudicial to their comfort and enjoyment of life. Now there are two classes of evidence before your Lordship: there is scientific evidence and there is non-scientific evidence; there is scientific evidence of a theoretical character and scientific evidence of the results of observation. You have had engineers; you have had chemists; you have had microscopists; you have had doctors and sanitary witnesses; and I think, perhaps, it will be convenient if I take them separately. I am not going to attempt to weary your Lordship and the Commission by, as I said, discussing that evidence in detail, but discussing the general considerations, and drawing one or two inferences from them. Now, taking the engineering evidence first, which has been directed, firstly, to the pollution of the water, and, secondly, of the mud. It is convenient to distinguish them in that way. You have had four gentlemen, I think, called by the City, Mr. Baldwin Latham, Mr. Mansergh, Professor Unwin, and Mr. Birch. They have laid before you certain tables which I venture to say are purely speculative and theoretical and based, upon assumptions which I think it is not difficult to show are purely fallacious. It is a curious thing to notice, to begin with, that all these gentlemen having erected their edifices upon the same foundation and of the same materials have arrived at results which are discordant amongst themselves to the extent of 27 per cent., and even 44 per cent. of the total, representing the amount of sewage and the amount of pollution in the river.

It is a little startling from what one would imagine was an exact science to find such descrepant results, but I do not think it is so startling as the unsubstantiality of the bases when you come to examine them. Now take the results of the tables put in by those gentlemen; they are all based upon one principle. Their object is to show, viewing it from an engineer's point of view as a purely mechanical question, what is the condition of the river and what is the amount of sewage in the river at different parts of its length; and the principle upon which they arrive at their conclusion is based upon certain observations of a thing which I am almost afraid to name in your Lordship's presence; viz., chlorine from which they deduce all these results. Put shortly it is this. We know the amount of water in each section of the river at high and at low water; I think one may assume that they do know that approximately. We can estimate, say they, the amount of that which is salt; that it is to say, the proportion of that which is sea water as distinguished from fresh water and sewage mixed together, by arguing from Professors Way's chlorine test. The argument is a very simple one, and I am not going to say that if the premises were correct, the result would not be correct. Sea water contains, say they, about 1961 parts in 100,000, fresh water an infinitesimal quantity, and sewage a little more, but still, as compared to sea water, an infinitesimal quantity. If you get, say they, at a certain part of the river a thousand parts of chlorine, you may at once conclude with very approximate accuracy that nearly half of that is sea water, because nothing else would produce that amount of chlorine, and I am not prepared to deny for a minute that, if you get the amount of percentage of chlorine in sea water, and that result, that that would not be correct. The first thing is the percentage of sea water in the mixture, the next thing is either fresh water or sewage—that is obvious; the next thing is to find, of that quantity, how much is fresh water, and how much is sewage or polluting matter, and that is arrived at in this way: We know, say they, the number of gallons of sewage you are discharging from the outfalls on any given day, and we know the amount of water that goes over Teddington Weir and from the other tributaries upon any given day; the proportion between those two represents the proportion in which the mixture in any part of the river is made up of fresh water and sewage; and therefore, that being a known proportion, we can divide the remainder, which is not sea water, into fresh water and sewage, and we can put these figures down upon the table and tell the Commission that there is that quantity of sewage in any particular part of the river. But that is not all we know; they say there is an immense amount of water going down every tide, and much of that returning. To put it shortly, half the water above Southend at high water has gone out at low water; they assume also a rather startling assumption, that the water which goes out to sea beyond Southend always comes back again, not other water, but the same water. Now just let me say a word or two with regard to these two assumptions.

First, very shortly, with regard to chlorine, all I have to say is this, that it is manifest, upon the face of the analyses and tables which they have put in themselves, that nothing is more uncertain and more variable from hour to hour and minute to minute than the result of any attempt to ascertain the amount of chlorine in the river; the results are uncertain to an enormous extent. I will only refer to one table to show you that, and it is quite enough. I will ask you to look to Table No. 15, put in by Dr. Tidy, which is headed "Analysis of samples of Thames water collected "at All Hallows Pier," on a certain day in August last year, and taken at consecutive hours. Now, of course, what you ought to have, if the chlorine followed a regular law, would be that at high water you ought to have the most chlorine, and at low water you ought to have the least chlorine, and there ought to be a gradual diminution of the chlorine from one to the other, and a gradual increase from low to high water. Now, if you look at the table at between 3 and 5, it being high water at half past 3, there are two analyses which give 151 parts of chlorine per 100,000. Then there is a sample taken at 7, and the chlorine has dropped to 64·8; that is right enough, because the tide is falling. Then there is a sample taken at 9 o'clock, when it was dead low water; the chlorine, instead of dropping, as it ought to do, has jumped up to 144, or nearly what it was at high water; and then at 11 o'clock, two hours afterwards, when it ought to be getting rather bigger, it has dropped down to 5. There is another at Crossness, which is equally startling, it shows similar eccentricities. I will refer to Table No. 7, samples of sewage water collected at Crossness outfall.

(*Chairman.*) Just let me ask you this—does this bear upon the great question of below bridge?

(*Mr. Bidder.*) It bears upon all the engineers' tables. I only want to show the Commission that it is impossible to trust to the analysis of chlorine, that it fluctuates in such a wild manner, whether it is owing to the or not I do not know, but it is perfectly hopeless to base anything upon it. And remember that it is the sub-structure of the whole of the evidence

of the engineers. I have no doubt for a moment that these samples are taken with perfect fairness and care and properly analysed, and that they really represent what was the case at that spot, at that particular moment.

(*Chairman.*) How on earth does it prove anything? I suppose the size of the river would tell you what quantity of water would flow in, and what flows down is known by gauging Teddington Weir, and the quantity of sewage is known.

(*Mr. Bidder.*) I am showing you that their system is a fallacious one—there is a certain volume of water in a certain reach, and these gentlemen profess to be able to tell you how many days' sewage there are in each block.

(*Chairman.*) They surmise that the water which has come back into the river has been already polluted, and that therefore there would not be such a dilution as if it were all fresh sea water which came in.

(*Mr. Bidder.*) I am upon a step before that; take any part of the river; we know there are three things: that there is a certain amount of fresh water which is coming over Teddington Weir; there is certainly sea water, but it is brackish; and there is sewage, and they want to know the proportion of the sewage. Now, to begin with, they ascertain that a portion of sea water will contain, say, 2,000 parts of chlorine. The river water and the sewage have so little that you may say that they have practically none compared to sea water. If you found a water at Erith which contained 1000 parts of chlorine, you could say unhesitatingly that that water is half sea water, whether it has fresh come from the sea, or whether it has been in the river a month; it must be a mixture which must be half sea water; and that is a statement I do not find any fault with whatever, if their figures are right. From that, they profess to show that the residue must be sewage and fresh water mixed together, and though I admit that Professor Way and the gentlemen who made the analyses are perfectly right in the analyses and figures upon which they based their superstructure, yet, whether it is that the salt water comes up in streaks or is unequally diffused, or that at times it is more salt and at times more brackish, I do not know; but, as a matter of fact, you cannot trust to one specimen of the river to represent the condition of the water at that spot five minutes afterwards. Therefore, to argue over a five mile reach, as they do, from a single sample, or a couple of samples, is perfectly illusory, as I submit.

Now I have Table 7 of Dr. Tidy's before me; it refers to All Hallows Pier, at high water; you recollect it is the saltest, it has most chlorine in it, and it is lowest at low water, when there is the least chlorine. That table contains a series of samples of sewage water collected at Crossness, taken hourly; evidently it is not the sewage taken at the outfall, but water in the river, because the outfall never contains chlorine to this extent; it contains scarcely any. Now you are told that it was high water at about half past eleven, therefore the samples, as you will see, began after high water, when the chlorine ought to diminish as the tide ebbs, because the water gets fresher. Now, beginning at half an hour after mid-day, you find 208–80; an hour later, and you find nearly double, 367; an hour later, you find 151; an hour later, and it has jumped up to 266. Now, without going further, these, I have no doubt, are perfectly fairly taken samples, you have the chlorine jumping about, doubling where it ought to diminish, and diminishing where it ought to be double. I merely mention that to show what a flimsy thing that is upon which to base such a superstructure as these tables profess to show.

Now I pass from that to show the assumption the other side seem to adopt, which seems to me to be equally erroneous, and that is the strength of the sea water. Now if, as your Lordship put it, supposing sea water contains 2000 parts, and that your mixture contains only 1000, your conclusion is that it is only one-half sea water; but if it is 1500, your mixture is two-thirds sea water. Now there is no doubt in my mind that they have given you sea water as much too strong. Dr. Tidy has given his analysis of sea water all over the world, and this astonishing result that they have given is that the Southend water, which they have gone by, appears to be stronger than the water in any other part of the world, with the exception of the Dead Sea; much salter than the Mid-Atlantic; that is to say, taking the standard which they have taken. But that is not all; upon certain of the days upon which the calculations were made we have given us by Professor Way, what was the actual standard of the water, not only at Southend, but at Margate; and it is very far below the figure which they have assumed. Upon one day, when they assume the proportion of chlorine to be 1961, it actually was at Margate 1770, which very materially alters the conclusions to which they have come. I know what the other side will say, that at Margate it was 1770 because that had been after a fresh which had diluted it. That clearly shows that the Thames is diluted with fresh water, for the North Sea has a great number of rivers running into it, and it therefore is not likely to have as much salt in it as the Atlantic, which has less rivers running into it in proportion; but, whatever it is, that which feeds the Thames is the sea water outside it, whether it be weak or strong.

Now the next hypothesis is a most astounding one, and, I venture to say, the most fallacious of all, and that is, having cometo the conclusion that there is a certain residuum which is made up of fresh water and sewage, in order to arrive at the proportion of that which is fresh water and the proportion which is sewage, they say we have only to look at the amount of sewage that you were pouring into the river upon that day, and the amount of fresh water which was coming over Teddington Weir upon that day, and, whatever is the proportion between those two, that represents the proportion of those constituents, fresh water and sewage, in that residuum,a most astounding proposition to arrive at. The sewage to a certain extent varies every day in amount and extent, and so does the water in Teddington Weir vary in amount and extent every day. We are not talking of the amount of sewage which has been found upon any particular day; there is upon their assumption something like 40 days' sewage in the river, yet all the way down to Southend, although the sewage was shot into the river a month before, and the amount of fresh water that is passing out at Southend had come in a month before, yet the proportions in the river upon that particular day are determined by them by the quantity coming in at Teddington Weir and from the outfalls upon that particular day. One witness went as far as to say that, if you put in a quart of fresh water at Teddington, another quart was pushed out at the other end immediately.

Now the facts are that, though eventually it flows out at the other end, yet it has to perform a certain number of oscillations up and down; and another thing is that, when you are talking of the lower reaches (assuming you have affected the amount of fresh water pushed down into the lower reaches of the river), that which you have pushed down is not the thing which you have put in above; and I ventured to illustrate that by saying that, if you had a long passage full of people, though you might push a man in at one end, it does not follow that a man will come out at the other, it might be a woman.

Now the case is capable of *reductio ad absurdum* in this way. Suppose the quantity of sewage flowing into the river is constant, and that you have twenty times the amount of water coming over Teddington Weir to that of the sewage, then they say that upon that day, all the way down to the sea, whatever is no sea water, is 20 parts fresh water and one part sewage Now suppose to-morrow the flood is over, and the fresh water has dropped to 10, then they say that all the way down the river the water in each block is 10 parts fresh water and one part sewage. If, for instance,

9 July 1883.

to-day there is 20 times as much water coming over Teddington Weir as sewage, and from that they deduce that in the tidal estuary there are 30 days' sewage, and that to-morrow it falls to half, they would say there are 60 days' sewage in the river and if the next day it fell to a quarter, they would tell you there were 120 days' sewage in the river. It is absurd to say that the proportion of the sewage in the river is determined by its momentary relation to the two sources of supply.

Then there is another thing equally fallacious, as it seems to me, the assumption that the same water which goes to sea past Southend comes back. As they told your Lordship, of all the water that is above Southend at high water half goes seaward of Southend at low water, and with it, of course, half of the sewage in the river. Upon the next high water there comes back water which fills the tidal area again, and they assume that that comes back with exactly the same mixture as it went out; but, in point of fact, although they admit the mixing action all the way down the river, which they admit is accelerating the motion of the sewage seaward to Southend, they assume that that stops at Southend, and that whatever had passed to Southend would come back again.

(*Chairman.*) As I understand, the effect of that argument would be that ultimately the river would be filled with Teddington water and sewage with no salt water in it.

(*Mr. Bidder.*) I really think it would come to that. Southend Pier seems to be the arbitrary point that they take; but if that is so, it would have been good at any other point, if they had taken Margate, for instance. But the strange thing is, when they were arguing to support the excessive saltness of the river at Southend, they took exactly the opposite view, because, I recollect, in answer to a question from Sir P. Benson Maxwell, I suggested that it was not likely that the water at Southend would be such very salt water; but I was told, "Yes, because the high "water at Southend comes in from the north; it is "fresh sea water; you must not assume that it is the "fresh water coming back again." Perhaps I had better give the Commission the reference to that. I was cross-examining Dr. Tidy as to how on earth he made out that the water was so salt, and Mr. Abernethy asked the question at 10,153,—"You see it is a very "large funnel-shaped mouth, and that the tide comes "in from the North Sea; would you expect to find "much fresh water?" To which the witness replied, "No, I should not. As a matter of fact, I should "expect to find very little.' That is rather inconsistent with the hypothesis that all the polluted mixture that comes out is carefully preserved in some mysterious way beyond Southend, and comes back as it went out. Therefore it does seem to me that every one of these hypotheses is open to the most serious objection, the fundamental one of all, the chlorine test, being, as I have shown, whatever the accuracy of doing it, utterly unreliable.

But there is one hypothesis which I must not lose sight of, which is, perhaps, the most important of all in considering what practical value to give to the engineers' evidence; that is, once sewage always sewage. Everybody round the table admits that there is a constant destruction going on, and that the sewage is completely destroyed whereas the gentlemen here say that, once sewage, always sewage; that no particle of it is ever lost; no particle is ever decomposed; that it is always sewage, and is always unaltered; that is their hypothesis. Now that is so obviously entirely ignoring one of the principal factors in this case, admitted on both sides, that it seems to me to dispose of the engineering evidence altogether.

Now, my Lord, there is only one other question, I think, touched upon by the engineers, which I need deal with before I pass to the chemical evidence, a sort of suggestion which was made—I do not think it was relied upon much—that we might be doing mischief by contaminating the chalk wells, because it was argued with perfect truth that wells near the river do fluctuate in their level with the tides, a perfectly true principle in hydraulics; and Mr. Baldwin Latham pointed to the chalk well at Grays, as to which he seemed to draw the inference that the chlorine found in it must have been derived from the river. Now Mr. Law has shown you that, so far from that amount of chlorine being unusual, there are numbers of chalk wells given in the Rivers Pollution Commission Report which contain abundantly more, and that it is not an exceptional amount; and furthermore I may point out that there was not a particle of evidence to suggest the slightest trace of sewage contamination in any of them.

Now, my Lord, I pass to the chemical evidence, and I confess I approach it with a great deal of diffidence. I do not pretend to master all the propositions which chemists put before you, I gather from themselves that no man in the present state of science is in a position to give absolute and positive results, or to draw positive deductions as to the amount of sewage present. I think it is admitted on all hands that such results as you do draw must be and can only be relative. You have three tests which have been taken by the chemists who have been called by the Metropolitan Board of Works, all of whom are very eminent men and as well qualified as anybody could be, to speak upon the question. We have three different ways in which we have dealt with the chemical question; one by ascertaining what they call the albuminoid ammonia present in the water. Professor Tidy says that albuminoid ammonia, in his judgment, is not, in a case like this, a trustworthy guide. Sir Frederick Abel and Dr. Dupré say, "as regards the absolute amount of sewage, per-"haps not," but if you conduct your analysis carefully, it is a guide as to the relative amount; so do Dr. Odling and Dr. Voelcker say. The second process which they have adopted is to ascertain, or to infer rather, the amount of putrescible or polluting matter by the amount of oxygen which is required to oxidise it by using permanganate of potash. That also, they say, and I think it is admitted on all hands, if applied under proper circumstances, is as good a test as you could have for relative pollution. Dr. Tidy seems to have some hesitation as to applying it in salt water; but I think I shall be able to show in a minute that it cannot be less reliable than what he has adopted as the test in salt water. But again, I say it is shown to be as good a test as you can have. It would be absurd for one personally to express an opinion upon it, but I will content myself with drawing attention to the evidence. The third process they have adopted is to observe the amount of free oxygen in the river, and to argue from that because there is a certain fairly ascertainable normal amount of free oxygen which the water should have; and, as I understand, when you find that defective it is a distinct indication that what is wanting has been used in burning up some nitrogenous or other organic matter.

Now it is a remarkable thing, and adds greatly to the weight, as it seems to me, to be derived from these observations (I am not going to trouble you with them in detail), that the results arrived at by dealing with the case in these different ways confirm each other remarkably, and, put shortly and generally, for I will not attempt to do more, amount to this. There is a certain amount of impurity in the water even at Teddington though it may be good enough for us; Londoners to drink, as you come down the river, the amount of impurity, gauged by either of those three modes, increases. It arrives at its maximum, they say, pretty nearly at the outfalls (and I will say so too); there it is from $2\frac{1}{2}$ to 3 times as great as it was at Teddington; the amount of impurity then gradually diminishes again until you approach to near Southend, when it has fallen, not only down to, but below what it was at Teddington, and the water is purer than it was when it started at the top of the tidal section.

Now if that be right, I cannot help saying that a total impurity which is only three times that which we consider to be consistent with a good potable water is not a very alarming thing. Of course we are

not speaking of the samples taken at the actual sewage stations, everybody knows that the sewage is far more foul than that; and that, if you went and dipped a can into the river within a few yards of the outfalls, you would get a far more concentrated mixture. I am speaking, not of the particular sewage stream, but of the area of the river down to and beyond the outfalls. Now it does not seem to me that anything like 2½ or 3 times the impurity of the Teddington water is a very terrible thing, not of course for a potable water, because nobody thinks of drinking it, but to live by the side of, and even to bathe in.

Now I will deal with the chemical evidence which was given upon the other side, and here I can only pretend to deal with it in a very general way. But I take Dr. Tidy, who has gone into the matter with the greatest care upon the part of the City, and he does not profess great confidence in two out of the three tests that we have taken, but he is confident in certain other things. I say I think that our tests are strongly confirmed by the fact that they seem to give very nearly identical results with theirs, notwithstanding Dr. Tidy has that doubt. But when you find by one process (which at any rate eminent chemists consider a reliable one) that you get this result: impurity rising from one to three, and then falling to one; and that, when you have a second result which gives you a rise from one to three and then falling to one, and again a third process which gives you a rise of impurity from one to three, and then again a fall to one, I say it seems to me that these are confirmed very strikingly. But Dr. Tidy says, "I prefer to take it "from the amount of organic carbon and organic "nitrogen which I find in the samples," and also he says, not only the "amount," but the "proportion" in which they are present, or, as he calls it, the ratio of the nitrogen to the carbon, because, as he says, "in "the river water as it comes over Teddington Weir "the proportion of nitrogen to carbon is very small; "I think it is only 1 to 8. In sewage the proportion "is very high, and if I find the proportion rises, I "draw the inference of the presence of sewage." Now what vitiates that, and what I see, in looking over the evidence, induced Dr. Frankland to say he gives it up as totally worthless, is this, which Dr. Tidy said he had regard to, but which he did not consider as having affected his results. But there is another thing first which we know to affect the presence of nitrogen, and that is sea water; that the ratio of nitrogen to carbon in sea water is greater than in sewage, so much so that in sea water Dr. Tidy tells us that the nitrogen is actually equal to the carbon in many samples. I took the trouble to trace the subject in this sort of way, and I will just mention, in order that it may be upon the notes, that those members of the Commission who care to test it may do so afterwards. It will be found that Dr. Tidy has given his analysis of sea water. I hope the Commission do not think I am going into too great detail upon this point.

(*Chairman.*) I am afraid I do not appreciate the value of it. I trust you are not troubling yourself with anything above Greenwich.

(*Mr. Bidder.*) No, it is general.

(*Chairman.*) Your drift is to show that the proportion of sewage to actual water in any place which you take is less than the other side would make it.

(*Mr. Bidder.*) That the polluting matter, not that which contains the sewage, but that which would be recognised as contamination, is very minute.

(*Chairman.*) After all, the question is whether it is more or whether it is less, and what does it do when it gets there? If it were double what it is, or if, somehow or other, its evil effects were annihilated, is not what it does the great question we have to consider?

(*Mr. Bidder.*) No doubt; but the two do bear upon each other.

(*Chairman.*) The other side give *a priori* evidence to show that it ought to smell.

(*Mr. Bidder.*) And my evidence goes to show that it would be a miracle if it did smell, except, of course, in the neighbourhood of the outfalls.

(*Chairman.*) After all, we shall have to ascertain whether it does smell, or no.

(*Mr. Bidder.*) There is an analysis given in No. 1 of Dr. Tidy's tables of sea water at Southend, showing that practically the nitrogen and the carbon are equal; each of them is ·3 grains in a gallon, and if you go back to his big table of analyses of samples collected all the way down the river, if you look at the amount of chlorine in any one of the samples and apply the proportion of nitrogen to the carbon, assuming that the chlorine comes up from the sea, and apply that to the chlorine as shown by the sample, that wonderfully modifies his results. But I will not weary the Commission by going into the figures.

Now I should like to refer your Lordship to the first table of Dr. Tidy's, upon which there are one or two remarks that I wish to make; I am endeavouring to avoid detail as far as possible, and one reason is this: because it bears upon the question in this way. We have heard a good deal about stench and offensive appearances and smells in the neighbourhood of Greenwich and Woolwich, in the upper parts of the river. Now if you recollect, Dr. Sorby told you, as the result of his microscopic analyses, that he had discovered a considerable maximum in the neighbourhood of London Bridge, and it becomes a material question whether what is observed in the part of the river above the point of the outfalls is not caused by sources of pollution for which we are not responsible at all. Now I know you were very much startled when Dr. Sorby told you that the water at London Bridge was more polluted than it was at the outfalls; that, gallon for gallon, it was more polluted; that was shown also by Dr. Dupré and Mr. Dibdin; but more than that, it is actually confirmed by Dr. Tidy. I will not weary you by calculating it now: but it was challenged weeks ago, and I say it has never been denied; and therefore may be taken to be absolutely correct. If you take these samples from No. 27, which is at Lambeth, down to No. 35, which is at Deptford, they have far more organic matter in suspension than the samples taken at the outfalls below or above, they are the worst of the whole lot. If you multiply the number of grains of suspended matter by the percentage of organic matter, you would get the number of grains of organic matter. Now take it from me that, if you do that in the case of these samples between Lambeth and Deptford, you get something over four grains of organic matter in suspension per gallon, whereas when you go to the outfalls it is something under two, and in the neighbourhood of Erith it is about one-and a-half, and if you go above, it is under two; in point of fact, the amount of suspended organic matter in that part of the river, from Lambeth to Deptford———

(*Chairman.*) I do not quite follow that; take the sample No. 27 at Doulton's.

(*Mr. Bidder.*) That contains 8·54 grains of suspended matter, of which 66 per cent. are organic matter. Now two-thirds of 8·5 are 5½ grains. Now take No. 45 at Barking outfalls, there are, in that sample, 4 grains of suspended matter to the gallon, of which 31 per cent. are organic. Now some of them are better, and some of them are worse; but, averaging them in that part of the river, you find it is under two grains, and in the part above Deptford it is over four grains.

(*Chairman.*) 5½ you have got it at, at Doulton's.

(*Mr. Bidder.*) Yes, but I do not pretend that that is a fair specimen—that is an exceptionally bad one. There is one as high as six grains of organic matter, that is at the Globe Wharf, No 32.

(*Chairman.*) I confess I do not understand this sort of thing—Putney is 4, and Wandworth is 1·4.

(*Mr. Bidder.*) Putney is 4 grains of suspended matter, of which ⅕th per cent. is organic, which is a little less than a grain.

(*Chairman.*) Below it is one-third of that.

(*Sir John Coode.*) And above, it is three times that.

9 July 1883.

(*Mr. Bidder.*) Therefore it is not fair to take an isolated sample. I take the whole group, and the remarkable thing is that at that very place where Dr. Sorby says he found the maximum of impurity in suspended matter Dr. Tidy says he found the same thing, and you will find the same thing in the diagrams of Mr. Dibdin and Dr. Dupré. The important thing is that that establishes in this inquiry as to whether these things which the gentlemen at the East and West India Docks, and at Woolwich, and at other places, have complained of, have not been caused by things other than the outfalls, that there are impurities above which, gallon for gallon, are worse than the state of things below the outfalls. And let me here notice an observation of Mr. Dibdin's that in 13 out of 20 observations the high water was better than the low, that is to say, that which had come up from the neighbourhood of the outfalls was better than that which had come down from the London Bridge direction. And it is not merely London Bridge: because we know there is the large West Ham sewage in the river Lea, and that is the Bow Creek. There is a very large floating population, which is very important. In some of the evidence to which I shall draw your attention there is shown to be a very large discharge of sewage at North Woolwich, just opposite to the pier. You will find some of the witnesses localise the stench and the offensiveness upon that very shore at North Woolwich, and close to that pier.

But now, my Lord, I will not trouble you with any more detailed figures. After all, what do these analyses show in the way of nuisance? Dr. Tidy himself, when I put the question to him whether, having the advantage of his analyses and having seen the river, he was prepared to say that the river Thames was in any way injurious to health, said he was not prepared to say that it was injurious to health. I put it also to other chemists with the same result, and I may just as well turn to some of the evidence. Neither could he say whether the more objectionable substances were referable to the outfalls.

Now there is a very important point, in fact, the most important question in this cause, which arises upon or is suggested by these analyses; and that is the question of free oxygen, because everybody agrees that the diminution of the oxygen is produced by the burning up of the sewage, and, as Dr. Tidy says, the fact of the diminution of the oxygen is a sure sign that the sewage has been burnt up. And he goes further; he says, all that does not sink must eventually be burnt up.

Now the question is, How far are we justified in saying, as we do, that that is an efficient cause which deals with the bulk of the sewage, and prevents it being anything of a nuisance, except the immediate local nuisance that I spoke of? Now nobody has gone into the question more clearly than Dr. Tidy, and as your Lordship was absent when he was examined, I will take the liberty of reading one or two of his answers, not only given in this inquiry, but also in his books written upon this subject.

(*Chairman.*) I think I know what Dr. Tidy said here, and what he had said before, that, if you turn sewage into a river flowing, in course of time it will become all right.

(*Mr. Bidder.*) He says a great deal more than that—he condescends to state the extent and the amount of the purification. He says, if you put one part of sewage into 20 parts of water, and let it flow for 14 miles, it will in the course of that distance have vanished as sewage. But there are one or two paragraphs in his evidence which are well worth reading, because they bear so entirely upon this question before you. In answer to Question 10491, Dr. Tidy quotes from his pamphlet on river water, and he says, "Let me briefly state my case and then "proceed to call my evidence:—(1.) If sewage be "discharged into running water, the organic impurities "will, I contend, after a flow of a few miles, be entirely "destroyed or got rid of, the water once again "assuming its normal condition of purity. (2.) That "this power of self-purification depends upon three "things: (*a.*) On the *subsidence* of the suspended "impurities brought down by the sewage. Thus in "the course of the river flow the grosser suspended "matters will be left behind. (*b.*) On the presence "of *animal life* in the river. After the water has "assumed a certain degree of purity (for it is not till "then that animal life thrives) the fish in the river "act as river scavengers, and so as general purifying "agents. (7.) On the *oxidation of the organic* "*matter.*" Then he goes on to describe the appearance of sewage in a river where sewage is poured in, which is wonderfully applicable to what we see in the Thames. He says, "The sewage at the outfalls is "probably offensive, very turbid, and more or less "brown, the exact colour and degree of offensiveness "being dependent partly on the character of the "sewage, but chiefly on the distance it has travelled "along the mains before its discharge into the river, "and the extent of exposure it has undergone. "Tracing the sewage stream down the river, it will be "seen to assume a black colour from the formation of "sulphide of iron. A further short distance, and the "black colour perceptibly decreases, and, as we watch "the flow, the blackness, I had almost written yard "by yard, disappears, until at last the river water "exhibits no signs of colour, turbidity, or smell. Once "again, very soon after sewage has been turned into "a river, the sewage fungus, that most absolute "indication of the presence of sewage in any quantity, "makes its appearance in the river. Excepting this, "however, all signs of vegetable life, barring possibly "a few straggling weeds, disappear; no fish, or fish "only of a certain kind, are to be seen. The banks "and river bed become black, and branches of any "trees that by chance dip into the water will be "seen covered with a black flocculent deposit. "A short distance further down the river (and "sometimes a very short distance indeed) the "sewage fungus cannot be found, vegetation "becomes clean and luxuriant, fish are abundant, "and the river banks and the river bed, "seen through the now clean water, show no signs "whatsoever of that black deposit." Now he says that does not apply to the river Thames, but I venture to say it is a most striking description of a great deal of what you see down at the outfalls. I will not trouble you by reading all that he said; but I must read one other paragraph, because it really is so very much in point; he says further on, in answer to Question 10,500, still quoting from his pamphlet, "There is first of all a remarkable fact to be noted in "the analyses of Thames water. The water at "Lechlade may be regarded as having assumed as "nearly as possible the character of river water. "Up to this point it will be conceded that practically "no sewage has found its way into the river. "Between Lechlade and Hampton, a distance of "110 miles, the river received (I am speaking of a "few years ago) the sewage of nearly a million "people. At certain places it is admitted that a "larger quantity of organic matter than was present "at Lechlade could be detected in the water. For "instance, one mile below Reading I have found a "quantity of organic matter at least double that "indicated at Lechlade, but four miles further on the "water was again found to have become normal, "whilst the organic carbon and nitrogen at Hampton, "notwithstanding the sewage of this million of people, "was rather less than at Lechlade. What, I ask, "had become of the sewage of this million people "if it had not been oxidised during the flow of the "river." Mind you, oxidised to such an extent that it was drank. Now it is said that the sewage of that million of people does not go into the river now, but that does not touch the question. Here is the fact that this very water above the locks had received the sewage of a million of people, and that after a short flow it had become sufficiently purified for people to drink. That is the principle upon

which Dr. Tidy has proceeded all his life, and he has summed up his views by saying that, if you take 1 in 20 parts and let it run 14 miles, it will be destroyed. I am quite aware that Dr. Tidy says you must not apply the proportion here, because what you are dealing with is not unpolluted water. But with regard to this particular case Dr. Tidy very frankly does acknowledge: By the time the sewage has arrived at Southend, I am bound to say that I think a great deal of it is mastered. He adds to that: When I say "mastered," I mean "burnt up." I recollect putting it to him at Question 10,568, and I see I quoted it to him from a former inquiry, and it touches it a little more nearly: "Given the state "of the Thames and the brackish water, there "being two hundred volumes of water to one "day's sewage, it will be burnt up, and your "answer was 'yes.'" Then it is curious to note that Dr. Letheby, in his report, which Sir Joseph Bazalgette quoted to the Commission, gives almost precisely the same views. He is speaking of the water at Blackwall, and he says, in answer to Question 12,907, quoting from the report of Dr. Letheby, "It is not "that the proportion of the organic matter decreases, "as will be seen by the tables, but its condition is "altered. This is no doubt occasioned by the action "of the air, and by the agitation of the running "stream, and the fact is amply demonstrated in every "river in the kingdom, especially in those which "receive the sewage of large towns. Those, there-"fore, who have looked upon the soluble sewage of "London as an unchangeable log of wood floating up "and down the river with the movements of the tide "have taken a very erroneous view of the thing, for "so prone is the organic matter to undergo change "and to complete its course of putrefaction that it is "doubtful if it exists as a putrefying body a few "hours after its entrance into the river. In fact, "while it has been traversing the sewers, it has "generally been so much agitated and broken up by "the movements of the current as to be in a very "advanced state of putrefaction." You will recollect that Dr. Tidy says that, in point of fact, in the case of the outfalls, it has gone through its first stage of putrescence before it arrives at the Thames at all, consequently a good deal of what left London as sewage has been turned into gas. Then Dr. Letheby's report goes on, "Almost the whole of the nitrogen has "become changed into ammonia and its sulphur into "sulphuretted hydrogen, and then when it reaches the "Thames it finishes the last stage of its putrefactive "career by the rapid absorption of oxygen and the for-"mation of compounds that are comparatively inert, so "that, partly by means of dilution and partly by the "destructive powers of oxidation, the Thames possesses "the means of self-purification, which is fully equal to "the contaminating injury to which it is at present "exposed." He adds, "I am even of opinion that the "discharge of the sewage into the river in such a way "that it would be diluted with not less than 200 or "300 times its bulk of water during each tide, and in such a manner that the insoluble portions would not "be deposited on the banks, would be a safe and "sufficient means of disposing of it." That is entirely in accordance with Dr. Tidy's views now.

Now, my Lords, Dr. Tidy says that is all very well; if you have got unpolluted river water, you may put in one part in 20, and in 14 miles it would be gone; but yours is not unpolluted water, you have put other sewage into it before. That of course is perfectly true; but instead of putting one part in 20, it has been shown you by the engineers that we put in one part in 260, that is to say, a thirteenth part of that which Dr. Tidy would admit is efficient; and consequently, according to Dr. Tidy's rule, supposing we were to put six and a half days in at once, supposing the water were unpolluted, it would not be too much, and that 6½ days' sewage would be disposed of in the course of that 14 miles. I need not say that it would be disposed of before the 6½ days were gone, because it would have gone in that time over some 300 miles.

Now test it in another way: after all, the agent which Dr. Tidy and Dr. Letheby relied upon for the burning up of sewage is the amount of free oxygen in the river. Professor Way ventured to say it would take 150 tons of oxygen to oxidise the stuff that we put into the water.

Now, upon that, when the figures are given you by Mr. Law and Dr. Dupré, it turns out that you have pretty well double that amount of free oxygen in the water when the water is at its worst. So that, tested in that way, it is true that the water is not unpolluted; but that, tested by the quantity of this purifying ingredient, you have far more than sufficient; and then, more than that, the fact is not disputed. I cannot argue it from Dr. Tidy's table, because it does not go far enough, but I will take you down the river, and when you get to Purfleet you find the water has been sufficient for its work, the purification is completed; and not only that, you have not only the amount of oxygen which is shown to exist in the water, but everybody agrees in saying that the affinity of water for oxygen, when deprived of its normal quantity, is remarkable, so much so that Dr. Tidy says that it is almost impossible, if you do not do your analyses at once, to get accurate analyses, because the water is absorbing and drawing in oxygen on all hands. If I might use a manifestly inappropriate expression, it is a sort of vacuum of oxygen in the river, the more it is short of oxygen, the more greedily it takes it up when it has the opportunity. Professor Way puts that very pointedly, he says there is no doubt that the river does take up oxygen from the air and from every source very rapidly.

(*Chairman.*) It is impossible not to believe what both sides agree to, that is to say, there is a purifying power in the water which, in some proportion, and at some time, will annihilate the sewage; but it is also certain that there is some smell. What we have got to deal with is what is the quantity of nuisance. What you are saying is very relevant for the purpose of showing that, if your clients say it does not smell, that is the reason why it should not; but we all know that. I suppose we are all possessed of that. Then the question is really reduced to this: knowing that there is that cause, to what extent does it operate, is there a nuisance in the river?

(*Mr. Bidder.*) That is the very point I want to make if you will forgive me; it is not enough for my purpose to have it admitted that there is a purifying influence which will do its work at some time or other; but that there is a purifying influence which is sufficient, and which does its work in a very short time indeed; and then, instead of there being many days' sewage in the form of sewage in the river, there is never more than a tide and a half, or a couple of tides, or something of that kind. I try to avoid wearying you with details in reference to figures and analyses, or even with references.

(*Chairman.*) That I understand, but I do not know that I explained myself clearly. Everybody admits that sewage poured into the river will, sooner or later, I suppose, in proportion to the volume of water into which it falls, or the rapidity of the flow of the water, become purified of the sewage; everybody seems to admit that some day it will go a little faster than others; what we have to see is, what does it do at Crossness and Barking; is not that so?

(*Mr. Bidder.*) That is really what I have in my mind, and that is why I venture to say that in this case Dr. Tidy's rule applies, and that practically at the end of, it may be, 14 miles, or a little more or less, the sewage has disappeared.

(*Chairman.*) What do you say to the men who say they smell it fearfully and dreadfully at Woolwich, and fearfully and dreadfully at Purfleet, and that, all the way between, the river is fouled and polluted, and that fish cannot live there?

(*Mr. Bidder.*) I have something to say to that evidence in a very few minutes, if you will let me get rid of this higher atmosphere, in which I confess I am by no means happily at home; but I will draw your

9 July 1883.

attention to this, which I will put as shortly as I can. I merely say that the universal opinion, at all events, the opinion of those best qualified to form a judgment upon this subject, is practically summed up by that statement of Dr. Tidy's that the 1 in 20 proportion for a 14 miles run destroys the sewage altogether.

(*Chairman.*) Let me make a remark to you which I think will show the reasonableness of what I am saying. If I were to pour a quantity of sewage from a watering pot into the river, that would be one thing; every particle of it would be mixed with the purifying water; but if you take the case of a large quantity of sewage going down in a stream and not being touched by the water upon either side of it, that is another thing.

(*Mr. Bidder.*) If it does not mix, it does not get the benefit of the water.

(*Chairman.*) If you were to pour out this sewage into the Gulf Stream or in the Mid-Atlantic, it might smell for a time, but if you were to spread it out by pipes, it would not smell at all. What we have really to deal with is the question of fact. Is it a nuisance to smell and sight, and health and fish, and everything else?

(*Mr. Bidder.*) Of course I am very glad to narrow it down, because I have had in my mind that what has been brought against us is a much wider charge than that. My learned friends have not merely relied upon the old fishermen who have come and said that they smelt a smell, and that it was nasty, but they have suggested injury to health from the water containing contaminating influences which were provocative of disease in places upon the banks of the river both above and below.

(*Chairman.*) I think we may say, as at present advised, that there is no evidence of any kind to that effect. (*After consulting with the other members of the Commission.*) I should not say this unless I had informed myself beforehand. We think that there is no trustworthy evidence that the health of the people is affected by this sewage. Just understand this: you know I do not mean to say that if a man is dredging, and is made sick by this smell, his health may not be indirectly affected; that no one could say. But we are all of opinion that the general health of the people on shore, or the people who go up and down the river, or the lads on board the training ships, or things of that sort, is not affected by it.

(*Mr. Bidder.*) That enables me to curtail this part of my remarks very much. I can put it in this general way that the proportion in which we put the sewage into the river is very far below the purifying power of the river, and that, whether you test it by oxygen, or whether you test it, as Dr. Sorby has done, by the microscope, the actual results obtained confirm the view that the destruction of the sewage is very rapid indeed. Recollect that Dr. Sorby showed you that of what went past him on the ebb only 40 per cent. came back again upon the flood.

Now there is another allegation that, though it may not be very bad now, it is growing worse every year. Now what I have to remark upon that is this. I do not think Dr. Tidy says so, but Dr. Frankland undoubtedly did say so. Now Dr. Frankland had only made one series of analyses, and I suggested to him that, in order to establish progress, you required to be able to compare one period with another; he had not got those means, but his observation was limited to what he could see when going from Charing Cross to Cannon Street across the river by the railway bridge, which he was in the habit of doing daily.

Then I think I could pass by Dr. Frankland's tables of the amount of detritus he supposed to come down the river. I do not think that I need occupy time to show how fallacious these tables are. They are tables based upon this sort of hypothesis, that, whenever $\frac{1}{100}$th of an inch of rain fell in London, that proportion of rain went into the sewers, and with it its due proportion of road side matter and sweepings. If anything turns upon Dr. Frankland's tables, there was this inaccuracy in them that they were based upon old observations of the amount of road sweepings which used to go down through the outfalls by certain old sewers in the old days before the catch-pit system was in general operation in London, and, in fact, upon circumstances totally inapplicable to the present day. When you take those two things together, and the third, namely, that he found the maximum amount observed at a particular time of the day, and calculated that it obtained through the whole of the day, I think I may take it that these tables do not show any reliable results. On the other hand, you have given you, both by Mr. Dibdin and by Dr. Dupré, a comparison of the analyses of the present day with those of six years ago, which shows most distinctly that the fact is that any change, though it is very slight, is rather for the better than otherwise.

Now, after what your Lordship has said upon that point, I think I may pass away from the chemical question with great satisfaction to myself, and probably to your Lordship. I will only notice, in passing, the very striking confirmation of our views and of the views of the chemists whom we have called, which is afforded by Dr. Sorby's observations, which have confirmed themselves in one or two ways, but which fit in remarkably with the observations of the chemists, and give and derive additional value to and from them.

Now, the next thing I ought to touch upon is the question of mud deposits. It is charged against us generally, and more particularly with regard to Erith Bight, that the result of the sewers has been to accumulate a large mass of what they hardly dignify with the name of mud, but describe as sewage filth, which is choking up the channel, and rendering the district uninhabitable on land and inaccessible by water. That is one of the most important things the Erith people rely upon, and I hope your Lordship will bear with me when I make a few observations upon that, for it really seems to be an entire misconception of what a mud bank is, and how it is formed. Of course it is obvious to everybody that a mud deposit is formed by matter that was in suspension in the water, which has been carried by the water, and must have been dropped in that place. It must have been in general suspension in the river before, and the reason why it drops at any particular place is that in that particular place the velocity is less, and that it has consequently an opportunity of settlement. That is the history of every sedimentary deposit, whatever it is made of, and in the particular case of Erith Bight, if the velocity in the place where that mud accumulates were greater, it would not deposit, and if it were less, more would deposit. Consequently, to talk of the sewers being the cause of the mud bank is an absurdity. It may be that a portion of the material of the mud bank is sewage. I want to distinguish between the two things: the fact of the bank being there, and what it is made of; I say that to talk of the sewers being the cause of the mud bank is absurd, it is simply dependent upon whether the force of the current containing the matter in suspension is more or less. In each case, in the last inquiry, we showed a diminution of velocity upon the part of the river, because, by certain dredging operations, the tide had been drawn to the other side of the river, and by the diminution of the velocity an absolutely necessary deposit occurred. And you have it proved here that contemporaneously, or just before the commencement and formation of the growth of that bank,—for I do not dispute for a moment that it has been growing, and growing lately,—that contemporaneously with that, I say, there were large dredging operations which have increased the sectional area upon the north side of the river, which consequently encouraged the tide there, and gave there, as you will find by the evidence, an actual eddy in Erith Bight, with the consequence that whatever was in the Thames water in suspension was there allowed to deposit. Now, it is given in Dr. Sorby's Report, and it was proved in the last inquiry, that the usual amount of suspended matter in

Thames water, or anywhere, is about 12 grains per gallon.

(*Chairman.*) Do you mean 12 grains in weight?

(*Mr. Bidder.*) Twelve grains in weight per gallon. Now that which we discharge with the sewage upon the tide, if you divide it by the water, is only one tenth of a grain, and it is divided into 250 times its volume of water, therefore only a very minute proportion of that is of sewage origin. That alone would lead you to the conclusion that where you do get a mud deposit a very small proportion of it would be sewage matter. But there is another fact, and that is this, which, I think, Dr. Sorby refers to in his Report, that the sewage mud is of lighter specific gravity than the general Thames mud. Now of course you would expect the heaviest particles to fall first, and that that which is lightest would probably be found in lesser proportion where you get the mud deposit than the other. Those two things taken together will lead us to expect a very small percentage of mud in any part of the river. Seeing that the percentage of mud in the river is very small, and is light, you would expect a small percentage. When you come to a chemical analysis of the mud, you have some witnesses who said some of it was black, others that it was black filthy stuff, and others that it was reeking, and various opprobrious terms were used, but none of them had analysed it to show that it was sewage. Dr. Tidy had not analysed it to show that it was sewage, he said, on the contrary, that it was very much like all other muds, but I think you have a table before you, showing a large series of muds in all parts of the river, and showing most distinctly that the worst muds are rather inclined to be found at the top of the river than down in these regions; and that is what your Lordship finds when you come to test these muds, particularly if you submit them to microscopical examination. You have had Dr. Tidy, who gives you descriptions of striated muscular tissue and yellow amorphous matter, and other things that he could not exactly recognise, but he detected those in the mud; but he says, very fairly, my method of examination is not quantitative. All I can tell you is that they are there, whether 1 part in 10, or 1 part in 10,000, I cannot say by the method I have adopted. Now Mr. Lionel Beale who had examined also microscopically, and who was called by my learned friends as a witness, went further; he said, "My observation "is that the remains of fœcal matter will not be the "$\frac{1}{1000}$th part of the bulk, something even less than "that, and the rest of it is all made up of sand." And not only did he go further, but Sir John Coode asked him this question, "The sand would not surely "be in the proportion of 999 to 1000?" and he said, "I have not examined it with that view, but I have "been astonished at the small amount of organic "matter in proportion to the amount of mineral "matter." Now this is the "reeking sewage mud" which they have reported upon.

Now, Dr. Sorby, when he examined it, tells you he has gone still more minutely into it, and he makes the fœcal matter in the sewage $\frac{1}{40}$th of a per cent. or 1 part in 4,500, so that there is, I may say, a concord of opinion that those uneducated persons who judged by the eye and gave vent to their feelings in their evidence (somewhat, I think I must say, prone to exaggeration) were entirely wrong when they called this sewage, or described it as anything like sewage.

And another observation of Dr. Tidy's I must call attention to, in which he agrees with our witnesses, namely, as regards the absence of smell in the mud. It is a remarkable thing, but you have many of the other witnesses who come and tell you the same thing. Now, Dr. Tidy was asked at Question No. 10,267, "You have yourself told me that you "were very much struck, in examining the muds "in this part of the river, with the absence of "smell"; to which he replied, "Very often that "is so, but at the same time I do not say I have not "smelt a smell over and over again." I knew it was on the Mud Inquiry that he stated that he had been very much struck with the absence of smell. Now let me remind you that Sir Frederick Abel, who was examined, stated that he put a rod into the mud and stirred it about and brought it up and smelt it. It is a matter upon which you can have very little doubt. When you try it for yourselves and examine it, and see whether it is offensive mud, you will find that it has no smell, excepting, as all muds smell, of mud; still I quite admit that you have had a good deal of evidence of some people residing and working in Erith and its neighbourhood, fastening upon that mud particularly, and telling you of offensive smells and nausea, and that in some cases men have been obliged to go away from their work. Now I do venture to think that all the evidence disproves the sewers as being the cause of it; and inasmuch as there is now made manifest another and a very proximate cause, a very palpable and sufficient cause, in the shockingly bad sanitary arrangements of Erith itself, I do not see why it should be suggested that the metropolitan sewage is connected with it. Because, what do you find admitted? That all along that mud bank there are local outfalls; I think it is four or five. I am not sure of the precise number, but they are described by Mr. Egerton, the surveyor, as sewers which discharge the sewage of a considerable portion of Erith. Dr. Jessell said the greater part of Erith proper was drained into these sewers; a very much smaller amount of course than what we discharge at our outfalls, but it is a question of the manner in which it is discharged. It is not discharged into the body of the river, where it would be fairly distributed, but it is allowed to dribble over the banks; it is allowed to lie festering in the sun; but you will read the description of what was seen by Mr. Chatterton and the others of our witnesses who went down there and found that there was a collection of slaughter-house garbage and other filthy refuse described by them, well calculated to make a most abominable nuisance. Now a couple of men named Harling and Clarke were called, who gave evidence of this kind, that they worked at the Erith Ballast Wharf, and that upon one occasion when they worked they were very ill. I do not know whether they did not say they had to go to the doctor; and there were some cases which Mr. Saunders gave of certain men who worked in the mud at Mr. Beadel's Wharf, their occupation being to clear away the mud which collected on the bank there, so as to keep the barge bed clear, and those men were said frequently to suffer from nausea. They were working within 80 yards according to Mr. Egerton, and according to Mr. Chatterton less than that, from the place where these sewers are pouring out their filth upon the shore. Is not that sufficient to account for the symptoms described? There is another man who is said to have been washing out his boat upon the bank of the river, and was obliged to go away and get some brandy and water at a public-house. Then Dr. Voelcker, you will find, says in answer to Question No. 16,368, "All I can say is that there was an abominable "nuisance arising from the refuse of the slaughter-"houses. The smell was most disgusting. We "counted no less than 14 sewers or sewage pipes "that discharged their contents upon the foreshore. "There were also entrails, bits of skin, and similar "animal matters all scattered about the shore;" and then he was asked, "Was what you saw at "Erith sufficient in your judgment to account "for the complaints of nuisance from the people who "work in the mud and along the foreshore there," and his answer was, "Yes, quite so. The fact is, it "was such an abomination that Sir Frederick Bram-"well who walked with us would not venture to go "very far." When you have palpable and immediate sources of nuisance like that, and on the other hand the fact proved, both by chemical analysis and microscopic evidence, that there is not a trace practically of sewage matter in the composition of the mud bank itself, excepting that which lies in this way festering upon the surface, and which is distinctly Erith

9 July 1883.

sewage, I say it is impossible to come to any other conclusion than that this is a nuisance arising distinctly from local causes, and that the Metropolitan Board of Works sewage has nothing to do with it. It is impossible to attribute what is felt and observed there to the less than the $\frac{1}{10000}$th proportion of organic matter which is formed in the mud of the river itself.

But now Erith seems to be particularly unhappy with regard to its sanitary arrangements, because they seem to be victims of bad smells of all kinds. In the first place, I notice, that Mr. Egerton tells us that they have a large dung wharf at Erith, at which, I do not know whether it is natural or artificial manure, is loaded or unloaded, but which at times has been so offensive that they have actually had to prosecute the lessee; and, in the second place, you have had described to you, and have seen, and probably smelt, the series of factories that there are between the outfalls and Erith,—factories which produce every kind of abomination conceivable on both sides of the river, which, curiously enough, we find from the documents which have been produced and put in, have been the subject of continual reports upon the part of the Erith people themselves, although, until the subject of this present agitation came forward, the sewage itself was never alluded to in their reports. It is a curious thing, on the other hand, to notice that, if it were true that the great nuisance and the bad smells that the Erith people complain of come from the river, it is a particularly favourite place, as we hear, for pleasure yachts; and, if you recollect, Dr. Sorby conducted his experiments there for a couple of months, and lived on the water, and never found anything offensive; that he washed the decks of his yacht with the water; and it is worth while noticing, *en passant*, though it is not of course conclusive, that the health of the inhabitants of Erith is admitted to be exceptionally good, in fact, astonishingly good. Dr. Jessell, the health officer, tells us that in 1880 the death rate was 14½ in 1,000, and in 1881 I think it had fallen to 11 in 1,000; in fact, from my knowledge of death rates, I may say it is almost unprecedented as far as indicating a very high state of health goes.

Another fact I should like to class with that is these training ships; no doubt, there have been one or two occasions in which there have been fevers and outbreaks of various kinds on board of them, but not traceable to the river. On the contrary, one of the worst of them, if I recollect right, turned out to be a case of measled pork or trichinosis, but it is a striking fact that you have a large number of boys living in what actually, according to the other side, is the sewage stream, and that their general health is admitted to be particularly good.

Still I know your Lordship has it in your mind that a large number of people have come and have given evidence with regard to actual smells that they have smelt, and offensive substances which they distinctly trace to the river. I have three observations to make with regard to them. In the first place, I think some of these statements are excessively exaggerated. The large bulk of these witnesses which my learned called were such witnesses (of whom he said he had 200 more) that I have no doubt at all you have only to go to the "Golden Anchor" again, and provide the necessary liquid refreshment which was provided upon that occasion, in order to get evidence, similar or stronger, if necessary. I put it in the first place that their statements are exaggerated and illusory; in the next place, I submit that they did not take pains to discriminate between what was due to the river and what was due to the factories or local abominations. Another observation I make is that the evidence is founded a great deal, in many cases it is distinctly said to be founded upon observations in the immediate neighbourhood of the outfalls. Now, nobody disputes that within a certain distance of the outfalls,—it is usually put at from 200 to 300 yards,—but no doubt, when the wind is blowing that way, you might smell it half a mile, and I have no doubt that the smell which these captains experienced, and which they have described, was a smell in the immediate neighbourhood of the outfalls. Take, for instance, Mr. Sandford,—it is somewhere about No. 600 in the evidence,—he said he had smelt the river between Jenningtree Point and Tripcock Point. Now that, if I do not mistake the map, just comprises the immediate neighbourhood of the outfalls. Practically, Tripcock Point, which is called Margaretness, is just above the Crossness outfall,—between the two outfalls,—Jenningtree Point is a little below between that and Erith.

Now you will find that Mr. Sandford said he smelt the river; that is where he smelt it, between Jenningtree Point and Tripcock Point. Then there is a gentleman of the name of Mr. Savory, a very appropriate name; he says, I smelt it principally in Halfway Reach; and then Mr. Shepherd, another witness, said he smelt it at Crossness. Those are witnesses who located their smell distinctly to the immediate neighbourhood of the outfalls, and it is worth while noticing that Mr. Savory, if you look at Question 1470, says he smells the factories at Erith, but he says he does not smell the Thames.

(*Chairman.*) There was a remarkable thing said by Captain Arthur Gillett, of the "Warspite," at Woolwich. He is asked at Question 811 "At what time of the tide do you notice it worst?" and he said, "At all times of the tide. I do not think it makes any difference." Now that cannot be, you know.

(*Mr. Bidder.*) I am going to make the same observation of a great deal of the evidence. To say it is just the same at all times of the tide is to say that the water which comes down from London Bridge is as bad as that which comes up from the outfalls. Now, Captain Gillett's ship is moored off Woolwich, and if he is near North Woolwich, it only confirms what I have suspected strongly from other evidence, that that is a special and local source of pollution which takes place in the discharge of the East Ham Local Board sewage, just by North Woolwich Pier.

(*Chairman.*) Upon my word, that is rather good; that the London sewage is not a nuisance, but the East Ham sewage is; that was a *lapsus*, was it not?

(*Mr. Bidder.*) No, not at all, my Lord; what I mean is this, that it depends upon how you discharge the sewage. At Erith the amount of sewage discharged is ridiculously small as compared with ours, but if you pour it upon the top of a mudbank, and leave it to ferment in the mud, you may make an intolerable nuisance. Half a dozen privies draining upon a bank of dry mud would probably make a greater nuisance than the sewage of the whole of London when properly put into the body of the river. What I say is that there is a very strong discharge of sewage at North Woolwich, which, as I gather from some of the witnesses, is discharged out upon a bank within a few yards of this spot.

(*Chairman.*) Have we any evidence of the manner in which the East Ham sewage is discharged?

(*Mr. Bidder.*) We have it in evidence that there is a sewer there that discharges through a reservoir, and the reservoir is discharged, I think, at low water. But whilst I am upon that point :. Question 3250 Sergeant Gillam was cross-examined by my learned friend, Mr. Michael; he was asked, "You said some-
"thing about the discharge from the penstocks at
"North Woolwich; is the river very bad when those
"penstocks are opened?" And he replied, "Yes,
"the water is discoloured for some considerable
"distance, and in warm weather it smells very badly.
"(*Q.*) How often does that occur? (*A.*) That I
"could not exactly say. I believe, once in every
"24 hours, but of that I am not positive." Now, if your Lordship will consider it, I am not so beside the mark. I admit, as regards the metropolitan sewage, that where it is discharged there is an offence. I do not pretend there is not, for a moment, and I say there is strong evidence that the same thing takes place at North Woolwich, and that, if

that were taken to our outfall, or discharged in the same manner as our sewage is, there would be no nuisance. Now, I was going to say, if you turned to Mr. Showell's evidence at Question 3421, you would find the same story. He was asked, "You have "spoken of the smell in the river. I understand that "the place which you identify as being that where "you have detected the most distinct and offensive "smell is on the north shore at North Woolwich," "and his reply was 'Yes.' (*Q.*) Was it near the "ferry pier? (*A.*) Close to the pier." I asked that witness if it was near the penstocks, and he said he did not know where it was. Now, at Question 4140 Mr. Naylor was examined by my learned friend Mr. Beaumont Morice, and he was asked in cross-examination, "Do you represent the sewage work at "North Woolwich as being offensive?" And he replied, "Yes, certainly. (*Q.*) And causing con-"siderable smell? (*A.*) Yes. I do not say it is all "caused from that one particular spot where the small "reservoir is, but from the larger one, the northern "outfall." He threw back the responsibility of it upon us, and then he was asked, "You represent that "one as causing a bad smell in the neighbourhood? "(*A.*) Yes. (*Q.*) And a sewage deposit on the "mud? (*A.*) That is so. (*Q.*) That you say from "your own knowledge? (*A.*) From my own know-"ledge. (*Q.*) And to a considerable extent? (*A.*) To "a considerable extent. I have occasion to cross "the water very frequently on business matters. "(*Q.*) By the Woolwich Ferry? (*A.*) Yes. (*Q.*) "That is where you principally notice the smell in "the river? (*A.*) Yes, because sometimes we have "occasion to wait upon the pier for a quarter of an "hour or 20 minutes." And I recollect another witness described the position of the outlets as being close to the pier. I cannot put my hand upon the name of the witness. All that seems to me to indicate that there is a local centre of offence there, just as much as our sewer, I admit, is a local centre of offence just at the point where the discharge takes place. Now, at Question 1470, Mr. Savory, who did not exaggerate so much as some of the other witnesses did, and who was examining officer of the Custom House officers at North Woolwich, was asked, "Have "you ever experienced any offensive smell from any "of the factories on either side of the river there?" And his reply was, "I have done so from the atmo-"sphere, but it did not appear to me to be from "the water. You can tell generally whether a smell "comes up from the water or whether it blows over "your head. For instance, we get that smell in our "houses at Erith; we do not get the smell of the "Thames. All these smells from the factories we "are favoured with in our dwelling-houses." Now, the question was asked, I think by your Lordship, whether anybody could be produced from Erith to say it did not smell. Now here is a witness produced from Erith who says most distinctly I have got the smell of the factories, but I never got the smell of the Thames at Erith in my house. Now what can you say, but that there is the grossest exaggeration on the part of a body of witnesses like Mr. McAlister, a clergyman of Plumstead, who smells it four or five miles inland, and that, when there is an east wind, it depresses his vital force. Now, it is not the first time that I have heard of the east wind depressing a man's vital force, and it is not necessary to pray in aid of the sewers of the Metropolitan Board of Works for that purpose.

Now, there are the fishermen. There come these fishermen and say, at least some of them do, that the proof of the pollution is that a number of little red worms used to be found in the river, but now we never find that there are any. But then you will observe that there comes another squad of fishermen to say that the proof of the pollution is that, whereas there never used to be any worms in the mud of the river, now it is swarming with them. This discrepancy is so noteworthy that my learned friend Mr. Bazalgette has kindly made me out a list of them on each side, and I find there are seven who prove the disappearance of the red worms, and four who speak to the presence of the worms.

Then there was another remarkable thing which we may recall; there was one witness who proved the existence of a new species of worm which fed on rope, but nothing else; he said they used to eat his ropes, and they were no use for bait, for nothing would eat them. Then there was another witness, Mr. Gatward, who said he smelt the sewage at Gravesend. I do not hesitate to characterise that as a gross exaggeration. There is another who said he smelt it all the year round. Now, when your Lordship and the Commission have been there, did you smell it; was there anything to smell? My learned friend says it was a cool day; all I can say is, if you have not been satisfied with that smell, go again and smell it for yourselves. If you go near enough to the outfall when the sewage is coming out, you will smell something very nasty, but if you get a reasonable distance further off, I venture to say you will confirm the evidence of all our witnesses, and mind you have a large number of them. You have Dr. Coleman, who resides at Woolwich, and he said he had never smelt the river until his attention had been drawn to the matter by this inquiry, since when he had smelt it once or twice. There was Dr. Rowarth, of the "Exmouth," who said he had never observed the smell. There was Dr. Wise, of Purfleet, who said he did not smell it. There was Captain Miller, of the "Castalia," who lives in it at Erith and bathes in it every morning, and there was Sir Frederick Abel; I should like to remind you of his evidence; it was not very long.

(*Chairman.*) That at 1,000 yards, I think he said, you might smell it when you were upon the river, but that after that, if you took it up and shook it in a bottle, you might still get the smell.

(*Mr. Bidder.*) Yes, but your Lordship will remember that persons travelling up and down the river are not bound to take it up and shake it in a bottle; if they do, they have themselves to thank for all they smell. Now he has lived at Woolwich for 30 years, not upon the North Woolwich side, but upon the south side, by the arsenal. At Question 16,271 he says that he has lived at Woolwich for the last 28 years, and that his house is within 250 yards of the river, and that his place of work is within 180 yards of the river; and then he is asked at Question 16,273, "Have you experienced any annoy-ance from the river," and his answer was, "I have "not. I may state that a walk upon the river wall, "and a breath of fresh air upon the T-pier at the "arsenal in the evening, has very often been my only "chance of getting anything like recreation and "fresh air; and I have never upon any occasion "experienced the least annoyance or inconvenience "from the river at that point;" and then my learned friend Mr. Bazalgette says, "You have given "your own experience. Now, of course, there are "many others employed at the arsenal amongst "whom you constantly move"; and his reply was, "I am surrounded by a small number of houses "occupied by official residents, with whom I am "more or less intimate, and I may state that we have "had during these 28 years the usual visitations of "sickness of one kind or another, but certainly in no "one instance has there been any case of sickness "which could be ascribed even remotely to the "outfalls. I say this not simply from my own "personal opinion, or as my own personal view, "but that is the view of medical men living in the "same place and attending upon the families." Then he says, "We are great sufferers from smells, "not only in the arsenal, but high up on Woolwich "Common, the smells extending as far as Blackheath, "all of which come from the large and increasing "number of factories surrounding the outfalls and "situated about the outfalls, and to a considerable "extent up the river as far as the Victoria Docks. I "believe there are as many as 14 manure works of

9 July 1883.

" one kind or other, large and small, and some of " them of the most offensive description." Now I cannot conceive a man more competent to judge of that than he is. Now, perhaps, I may read this further answer, because it has a bearing upon what he was cross-examined about. He was asked at Question 16,301, "Now, with regard to Woolwich " itself, is it not the fact that complaints have been " made by residents as to the sewage?" And his reply was, "Not to my own knowledge. I believe " that upon several occasions complaints have been " made of smells which, not unnaturally, have been " ascribed to sewage, because they have been due to " offensive odours something like, though much more " intolerable than, the odours evolved from sewage. I " refer especially to the odours coming from the fish " manure works, which are so disgusting that I trust " the Commission may have the chance of experienc- " ing them for a moment. I am not at all surprised " that they have been ascribed to emanations from " excreta, for I am convinced that in many instances, " and certainly at Woolwich, smells of this descrip- " tion have been mistaken for smells emanating from " the sewage outfalls. (*Q.*) However, you agree " with many of the witnesses that you can dis- " tinguish between the sewage outfalls and the " factory smells? (*A.*) The educated nose can; the " popular nose, when it is in the neighbourhood of " the sewage, would say, that is a sewage smell, when " it smells any smell."

My Lord, I cannot help thinking that that accounts for a great deal of the evidence which has been brought here; the neighbourhood abounds in smells, and that is the very reason why the outfalls were put down into that neighbourhood; but, taking Sir Frederick Abel's evidence, it seems entirely to negative any smell being traceable to the river when he lived there. If you think Sir Frederick Abel is right as regards Woolwich, then what am I to say as regards Greenwich, which is higher up? It is impossible the smell can skip Woolwich, and then reappear higher up at Greenwich from the outfalls. But there are smells traceable at Greenwich, and one gentleman said that when he went across the river he was always sick. I confess I cannot understand it. I suppose it is the same place at which one always lands when one goes on a summer evening to enjoy a fish dinner, and one must not quote one's own experience, but I might say I have never experienced it myself.

Now I will draw attention to this. Captain Gillett stated, not only that there was a smell, but that there were slate-coloured patches which came to the surface and floated up and down the river, more especially in the summer time.

(*Chairman.*) You are referring to No. 828.

(*Mr. Bidder.*) Yes, he says it came up in great masses of black stuff, sometimes as big as this room. Now there is another gentleman of the name of Lewis who, at Question No. 5020, also spoke to that, but he added another fact about it, which seemed to indicate that it was not the result of the outfall. He describes this matter floating about in black patches; " it seemed like floating mud, as it were, in black " stinking matter. As soon as you touched it, it " tumbled to pieces." And at Question 5018 he says that in the year 1880 "the river was very black " indeed during the summer, say, from Jenningtree " Point right up pretty well to the Cherry Garden " Pier."

(*Chairman.*) That is at Rotherhithe, is it not?

(*Mr. Bidder.*) Yes, at Rotherhithe. Then my learned friend Mr. Lumley Smith asked him this question, "Had that occurred before within your knowledge?" He had said that this occurred in July 1880, and he says that it had occurred in 1858.

(*Chairman.*) The water which was coming from the outfall might find its way up to Cherry Garden Pier, but according to the evidence that would be deodorized and destroyed.

(*Mr. Bidder.*) One must not say that it would not find its way, because according to the analysis some of the salt water comes up there; still Cherry Garden Pier is a good many miles from the outfall, and if any went up there it should be a very small proportion.

(*Chairman.*) One way in which it might be carried up would be by the mixing action.

(*Mr. Bidder.*) Yes, but what I want to show you is that the same phenomena happened in 1858; now that is before the outfalls, which were not opened until 1865. If you look at Question 5029 in the evidence of Mr. Lewis, who is the port sanitary inspector——

(*Mr. Webster.*) You will find he says it was much worse then.

(*Mr. Bidder.*) Be it so; but then at 5023 you will find he says that the patches might be about the size of the table, floating up and down; and then at the bottom of the page, when he is asked whether it had occurred before, he says it occurred in 1858; and then he is asked at Question No. 5032, "In 1858 " do you remember anything similar to what you " saw in 1880?" And his answer is, "There was a " greater amount, and it lasted a longer time."

(*Mr. Webster.*) He denies its being in patches, in answer to Question No. 5039.

(*Mr. Bidder.*) He says the same thing occurred.

(*Mr. Webster.*) That is your view of the "same thing."

(*Chairman.*) He says in 1858 it was a full black ditch. I do not quite understand that.

(*Mr. Bidder.*) Why I refer to that is for this reason: if he is right, it shows that that was produced by causes certainly other than the outfalls, or at all events might be produced. I do not say it entirely excludes the outfalls, but it is an extremely unlikely thing that up as high as Cherry Garden Pier you should have a concentration of filth produced from these outfalls in that way. And again, I have to remind you that there are a number of other sources of pollution distinctly identified as occurring in that very part of the river. The North Woolwich sewer I have spoken of—the West Ham sewer draining into the Lea, draining 120,000 persons, besides all that floating population of something like 20,000; and, connected with that fact, we have shown you by the evidence of Dr. Tidy that it is the matter in suspension that makes patches, not the matter in solution; and that as regards the matter in suspension that part of the river in the neighbourhood of London Bridge, and down as far as Deptford, is twice as bad as that in the neighbourhood of the outfalls. Now, patches must be made up of matter in suspension and of organic matter, and, seeing that you have twice as much of that in the upper part as in the lower part, it appears to me that you have a very adequate cause of these patches and this apparent pollution.

Now my learned friend Mr. Bazalgette reminds me, though it is probably in your mind, of a minor point in connexion with the mud. There has been a good deal said about its blackness as indicating its filthy character. Now Sir Frederick Abel has explained that, and he says that, in point of fact, the blackness is not any indication of putrescence, but that, in point of fact, it is caused by sulphide of iron. In answer to Question No. 16,244, he says, "If, by the putrefactive " decomposition of the nitrogenous organic matter " suspended in water, sulphuretted hydrogen be " evolved, this iron compound will fix the sulphur " from the sulphuretted hydrogen and will act " equally upon the other sulphur compounds, pro- " ducing sulphide of iron, which sulphide of iron " gives that black appearance to the mud, conveying " to the uneducated mind a notion of filth and im- " purity which is erroneous, inasmuch as it is an " indication of the purifying action of the mud " itself."

Now there are only one or two minor points which, it strikes me, are worthy of notice in that evidence produced by my learned friend Mr. Beaumont Morice. You have a great deal of evidence about the fish—

you know exactly what our view is about the fish question; there is not the slightest doubt about it, there has been a great disappearance of fish there, I believe, owing to the disappearance of the oxygen in burning up the sewage—the same thing as Dr. Tidy in his pamphlet pointed out was the inevitable consequence of putting sewage into a river and using up the oxygen.

Then there is only one other thing to which I will call your attention, viz., that Captain Miller of the "Castalia" was in Galleons Reach for a long time, and he declared he never smelt the smell there. And it is singular that that is between Woolwich and other places, so that you smell the smell at Woolwich, and you can smell the smell at the outlet, and you do not smell the smell at midway, which seems to confirm our evidence.

(*Chairman.*) Now what do you say to Captain Burstall; he is a witness of unimpeachable veracity, and, as it struck me, of very great sagacity; he is the captain of the Thames Conservancy boat.

(*Mr. Webster.*) And he has been so for 40 years.

(*Mr. Bidder.*) I have the greatest respect for Captain Burstall, but I confess I think his nerves have got the better of him. No doubt, he has smelt it near the outfalls, but I think his recollection or his imagination have carried the smell further than it extends. There is no question that anybody may go to-morrow or to-day and smell a filthy smell if they go near enough to the outfalls, and if the wind happens to be blowing in their direction it may go a little farther, but it only comes to this, if you are perplexed between two bodies of witnesses, why not go down again and satisfy yourselves, it is not like something that has happened and is past and cannot happen again.

(*Chairman.*) I think we have said that, if there never was any greater nuisance than we found when we went down there, it would not be worth mentioning, and I rather think Mr. Beadel, Mr. Beaumont Morice's client, said the same thing.

(*Mr. Beaumont Morice.*) It was a very cool day when you went down.

(*Chairman.*) It was a cool day and very high water, and plenty of fresh water over Teddington Weir, everything in the Board's favour.

(*Mr. Bidder.*) I am told now it begins to smell at 65 degrees, and that the temperature of the river water is now 68, so that you ought to find it smelling abominably.

(*Sir John Coode.*) I think you may safely leave that to the Commission.

(*Mr. Bidder.*) I say, wait until the warmest day you can find, and go down then and see whether you can find anything more than what I have admitted from first to last as being the immediate local effect. And, as I say, you cannot get rid of that; put the sewage where you will, you cannot find up and down the Thames a better place to put it; but as regards the general effect of the evidence, I venture to think the evidence upon the subject is all either exaggeration or misconception or want of discrimination between one source and another, or mistake as to what the source is altogether.

I am reminded that one consequence, if you were to put the sewage below Gravesend, would be that you would have no fish in the Thames at all. They are happy now that the sewage is put in where it is, but if you moved it below Gravesend, they would not come up the river at all.

Now I am very much obliged to your Lordship and the Commission for listening to me with such attention and patience in such a very dreary business. I do not think I have any further observations to make upon it. I think you had better trust to your own noses and eyes. Even if my learned friend Mr. Beaumont Morice is permitted to call up a second batch of witnesses, I have no doubt he can do so with perfect ease, but I think that neither your time nor ours will be profitably occupied in rehearsing that business again.

(*Chairman to Mr. Beaumont Morice.*) We do not know that we shall avail ourselves of any of the army of witnesses you are ready to call, but we really think you ought to give a copy of the names to the other side.

(*Mr. Webster.*) Of the names?

(*Chairman.*) I think I should say, of their statements, in candour and fairness.

(*Mr. Webster.*) I think my learned friend Mr. Beaumont Morice will be perfectly willing to do so, but a number of them are persons of superior position who expressed a wish not to be badgered by counsel, and perhaps their proofs have not been taken.

(*Chairman.*) I do not mean, of their proofs, but a list such as we have before us, because, even though we do not call any of them, we may be impressed by the number. And possibly (*to Mr. Bidder*) you might give us a list of another 500 upon your side.

(*Mr. Bidder.*) Sir Benson Maxwell gave us a pledge that we should have the same privilege reserved to us.

(*Mr. Webster.*) I shall be able to point out to you what the Board of Works have been able to do in the way of getting up witnesses. I think your Lordship has mentioned, incidentally, Captain Miller, who, except the medical officer, is about the only independent witness that the Board were able to get.

(*Chairman to Mr. Webster.*) We will not want you to commence to-day.

(*Mr. Beaumont Morice.*) I shall want to say something, considering it was in consequence of my memorialists' representation that this distinguished Commission has been appointed, and seeing that my learned friend Mr. Bidder has made a direct attack upon the drainage of Erith.

(*Chairman.*) But the Erith case and Mr. Webster's case are the same.

(*Mr. Beaumont Morice.*) But I have brought forward special evidence with regard to Erith.

(*Mr. Webster.*) If you begin at 12.30 on Wednesday, then I will undertake that my learned friend Mr. Beaumont Morice shall have an hour out of the day. I shall not occupy the whole day. But there is a table I wish to hand in with regard to the statement that it did not rain at the same time at Greenwich and Kew; the discrepancy arose from the fact of their having only taken over ·25 of an inch of rain in 24 hours.

(*Mr. Bidder.*) Does it always appear to rain at Greenwich when it does at Kew?

(*Mr. Webster.*) In this particular table it does.

*The document was handed in. See Appendix C.E.*

(*Mr. Bidder.*) As regards this further evidence, you will exercise your own discretion.

(*Chairman.*) We will consider it.

Adjourned to Wednesday next at half-past 12 o'clock.

# FORTY-SIXTH DAY.

## Wednesday, 11th July 1883.

PRESENT:

THE RIGHT HON. LORD BRAMWELL, F.R.S., IN THE CHAIR.

SIR JOHN COODE, Mem. Inst. C.E.
COLONEL C. B. EWART, C.B., R.E.
PROFESSOR WILLIAMSON, F.R.S.
FRANÇOIS DE CHAUMONT, Esq., M.D., F.R.S.
THOMAS STEVENSON, Esq., M.D.
WILLIAM POLE, Esq., F.R.S., *Secretary.*

11 July 1883.

(*Mr. Webster.*) My Lord, I have now to endeavour to make a few observations to your Lordship and the Commission upon this matter which is before you; and may I be allowed to make one preliminary observation, and to ask for your Lordship's indulgence; and more particularly for the indulgence of what I may call the scientific members of the Commission. I am vain enough to hope that in the old days upon matters of law I may have been of assistance to your Lordship, and in some scientific cases I might hope to be of some assistance even to scientific gentlemen, but this is not a case in which I could venture to hope to be of assistance to the scientific members of this Commission. Any observations I may have to make upon scientific points will be supplied to me by others, and I trust you will forgive me if I do not always use correct expressions upon the scientific points.

My Lord, I do not propose to attempt to argue the scientific question out at length; I think at the present stage of the inquiry it will not be my duty to do so, because I have to call your attention, I think, mainly to the question of whether there has been,—(I will not say a nuisance) but anything calling for substantial complaint. But I shall, incidentally, in connexion with that question, call attention to three or four leading scientific points for the purpose of seeing how far, when the Commission come to consider the evidence before them, the scientific evidence given bears upon the existence of anything which has been complained of, whether it is called a nuisance or not. I propose to comment very briefly in the course of my own observations to your Lordship and the Commission upon what my learned friend Mr. Bidder has said, and not to endeavour to deal seriatim with the points he has taken. What I propose to do is, first, to call your attention to the scientific matters upon which I ask the attention of the Commission, and then to ask attention to the matters of fact with which I feel more competent to deal, and which I think are of the greatest importance. I will ask you to notice one matter which was mentioned by my learned friend Mr. Bidder incidentally. It is quite true that the Commission at present have not gone into the question of any remedy or alternative scheme, or anything of that kind, but my learned friend Mr. Bidder, as part of his argument, indicated to your Lordship that any change must mean the change of going further down the river with the outfalls. Now, on behalf of the Corporation of the City of London, I ask the Commission distinctly to understand that at present they have expressed no such opinion, nor, so far as the evidence has gone, is there any ground for believing that they would ever suggest any such opinion if they were asked to assist. But what I am going to call your attention to as the principal fundamental cause of nuisance, if nuisance does exist, or is growing, is the turning out of solid matter into the river at this particular point. I have no intention of discussing before your Lordship whether the point is a right or a wrong point, but, assuming the point to be right, what I desire to say in answer to my learned friend Mr. Bidder's suggestion is, that we do not at all approach it from the same point of view. In the judgment of those who advise me, other questions would have to be considered, of as great or of greater importance, as to how far it would be right to send out the sewage bodily with its solids into the Thames at all. I may refer to the line of thought which has run through the deliberations of the Rivers Pollution Commission, which has been, as your Lordship and the other members of the Commission know, towards improving the effluent water which was sent out, as distinguished from sending it out in a whole stream. I mention that, because we wish it to be understood that the question is not only where the sewage should be sent out, but that there are other questions both of circumstance and degree, as to the way in which this question should be dealt with.

Now I want to make two or three criticisms as to the way in which this case has been dealt with scientifically; and they are rather in the nature of criticisms upon matters of principle, which I think the Commission will have to consider carefully if they deal at all with the scientific part of the case; and the first criticism is one which I venture to make upon the views presented by the two bodies as to the amount of solid matter which there is in sewage. Now I can very shortly put this before the Commission, and they will see why it is of importance when they come to examine the evidence for themselves. Dr. Tidy and Dr. Frankland consider about 50 grains a gallon is the average quantity. Dr. Duprè on behalf of the Metropolitan Board of Works, takes 25 grains as the average quantity; Mr. Dibdin says 27·39 grains is the average quantity of the suspended matter. Now, I ask the Commission to pause before they would adopt as the basis of any conclusions they may draw, or any recommendations they may make at the suggestion, that either 25 or 27 grains is anything like the right quantity. It is admitted that in every one of their analyses they have excluded all sewage, all effluent from the sewers coming down when there is anything like storm water, or anything like an excess of quantity, and I submit to the Commission that, upon their own tables and their own evidence, a large amount of solid polluting matter comes down in suspension at periods when the sewers are surcharged. I am not dealing with the storm overflows up the river, but I am dealing with sewage brought down which has in it more than the ordinary house sewage. I am dealing with the effect of a sudden storm of rain flushing the sewers out, and bringing down a large amount of road detritus and things of that kind. Dr. Tidy points to this, which I think should be brought to the notice of the Commission. Your Lordship may remember that Dr. Frankland himself found that Messrs. Hoffman and Witt recorded 103 grains per gallon. Dr. Frankland and Dr. Tidy found 119 grains, that is at Question No. 6256 of the evidence upon the Mud Inquiry, which my learned friend, Mr. Bidder, referred to. Mr. Keates, for the Metropolitan Board of Works, in the same inquiry found 95 grains per gallon, that is at Question 9980 of the same evidence; but it appears, I think, more strongly than ever when I give your Lordship and

the Commission the result of the present analyses. The Board have taken 229 samples; out of those there is only one sample, No. 177, which contains above 60 grains. There are only six between 56 and 60; the numbers are 92, 212, 303, 175, 106, and 114, and there are 21 samples containing between 40 and 50 grains; and the chemists who were examined for the Metropolitan Board of Works have stated that they have arrived at the conclusion of 25 grains, and 27·39 grains; and they have expressly said at Question No. 11,058 that whenever they have given details of suspended matter they have invariably omitted all samples taken during the time of storm. Now, we do consider that, as the matter has been put pointedly before the Commission, it might be a very misleading guide in the future, having regard to the experience of this Commission—as any incidental finding of theirs must have a very large effect upon anything which comes afterwards—we consider, I say, that it would be very dangerous if so low a standard were adopted as that of the Metropolitan Board of Works.

(*Chairman.*) Do you consider there is more matter in suspension at the time of the storm overflows?

(*Mr. Webster.*) Yes, we do, and more polluting matter.

(*Chairman.*) Have your people made their calculations upon the basis of taking the storm water?

(*Mr. Webster.*) They have included it.

(*Chairman.*) How do you account for the greater quantity of matter in suspension?

(*Mr. Webster.*) Because, in the first place, a scouring of the small drains takes place, that which sticks to the sides is brought down. In the next place, the heavier particles are removed by the greater flush of water; and, in the third place, the road, which will only dry up a lesser quantity of rain, is flushed and swept by the larger quantity of rain.

(*Chairman.*) The polluting particles are those that stick to the sides.

(*Mr. Webster.*) Those are among them, and upon this point I am only quoting the evidence of Mr. Keates, who has died since he gave his evidence. I find, in several samples, he took the storm water; that is stated at 9980 in the Mud Inquiry. I refer to that for this simple reason, that it is in accordance with experience which has been derived by numbers of chemists, both in England and abroad.

(*Mr. Norman Bazalgette.*) Pardon me for interrupting you, but you gave the Commission a reference to No. 11,058, to the effect that Mr. Keates carefully suspended his inquiry during flood times.

(*Mr. Webster.*) No, I gave the reference to the Mud Inquiry as 9980, which was on the storm outfalls.

(*Chairman.*) You did give a reference to Question 11,058.

(*Mr. Webster.*) That is in this inquiry.

(*Mr. Norman Bazalgette.*) It was Dr. Frankland who said that Mr. Keates carefully suspended his sampling.

(*Mr. Webster.*) Any correction as to matter of fact I shall be very delighted to have. I am only too anxious not to misrepresent anything, but I undertake to verify every reference.

(*Chairman to Mr. Bazalgette.*) What is your objection?

(*Mr. Norman Bazalgette.*) That 11,058 is the evidence given by one of my learned friend's own witnesses, who says that Mr. Keates suspended his sampling during flood time; it is not our evidence at all.

(*Mr. Webster.*) I will quote every answer I have given. I state that in 11,058 there is the statement made that the analyses were made from samples from which flood quantities were excluded, and I have quoted the answer to 9980 upon the Mud Inquiry, in which Mr. Keates then found 95 grains in the storm water, when it was subject to storm excess. I have also quoted the answer to Question 6256, in which Dr. Frankland and Dr. Tidy found 119 grains in the sample of water, and I have mentioned Messrs. Hoffman and Witt, who recorded 163. I am glad to be corrected upon a question of fact, but not upon an argumentative question.

(*Mr. Norman Bazalgette.*) You said that Dr. Frankland and Dr. Tidy gave 50 grains as the suspended matter per gallon. Dr. Frankland's evidence is from 23 to 25 grains, and he says, in times of storm, that is raised to 44 and 45.

(*Mr. Webster.*) I repeat again that the Commission shall judge when they come to consider the whole of the evidence.

(*Chairman.*) It would be better to set this right at once.

(*Mr. Norman Bazalgette.*) I refer your Lordship to Question 10,344, and after that to Question 10,346, it is Dr. Tidy cross-examined by my learned friend Mr. Bidder.

(*Mr. Webster.*) Dr. Tidy is asked at 10,346, "Now "I understand you to say that the increase during "the time of heavy rain and storm in your judgment "raises that, of course we know it must raise it, but "raises it until it is equal to 44 or 45 grains; what is "your ground for that statement?" To which he replied, "My first ground for that is the experiment "of Dr. Frankland. In the Report of the Rivers "Pollution Commission, page 29, Dr. Frankland gives "a series of analyses, and although I am quite aware "that you may take objection to one or two of the "high numbers, nevertheless it gives an average of "between 45 and 50 grains. Then, secondly, during "a storm our own experiments gave some very high "numbers, which numbers in the main (there was a "little discrepancy, owing, no doubt, to the different "times in which we obtained the sample, or the "different condition in which we obtained the sample) "were agreed to by Mr. Keates. And I would just "say that Dr. Frankland and myself, upon the 30th "of December, if you look at the answer to Question "No. 6227 upon the Mud Inquiry, found 119 grains "of suspended matter in a gallon, whilst Mr. Keates "admitted that he found even 95 grains." Now I am in the recollection of the Commission; have I misrepresented one word? The statement is distinct. My learned friend, Mr. Bidder, was cross-examining Dr. Tidy upon the statement of Dr. Frankland, and the point of his question was that it assumed that it was raised to a standard of 44 or 45 grains; and Dr. Tidy gives as part of his reason the fact I have brought to your notice.

(*Chairman.*) Dr. Tidy says, at No. 10,349, "But "the point I am trying to make clear at the moment "is that, though I admit 25 grains to be the normal "amount of suspended matter in a gallon, yet the "time when we get storm sewage is when we bring "up the average enormously," what does "enormously" mean?

(*Mr. Webster.*) It is explained in answer to Question 10,346, it is taken at 50.

(*Chairman.*) Does anybody say what the proportion of pollution is?

(*Mr. Webster.*) Not in this part of the evidence, but I will come to that directly. I am dealing with the solid matter for the moment. Now I mentioned, when the interruption took place——

(*Chairman.*) You must not blame Mr. Bazalgette for it. Even if he turns out to be wrong, he only undergoes the fate which we all undergo more or less.

(*Mr. Webster.*) But I will say here that every reference is given on my notes, and my learned friend shall see them if he likes, and write to the Commission, and point out any mistakes that I have made as to matters of fact afterwards.

(*Chairman.*) This is a most mysterious thing; one cannot fail to perceive that there may be an accumulation, that the first storm water brings it down, and the percentage is very considerably added to; but what if there is a storm every day for a month?

(*Mr. Webster.*) What I desire to bring to your notice is that to exclude all storm water samples, as Mr. Dibdin and Dr. Dupré have done in this case,

11 July 1883.

cannot be an accurate mode of proceeding. Now I will endeavour to supplement what I have to say, by saying that the Rivers Pollution Commission took as the average 48·5 grains of suspended matter in the London sewage, and the report of Mr. Keats to the Metropolitan Board of Works upon the working of the A, B, C experiment gave 57 grains; that you will find stated distinctly in Mr. Baldwin Latham's evidence in answer to Question No. 4734. I have brought before your Lordship sufficient to ask your Lordship and the scientific members of the Commission to pause before they adopt anything so low as 25 or 27 for the purpose of their consideration afterwards.

Now your Lordship asked me whether I could tell how many of those grains were actually polluting matter. I cannot do it in that way, but I am now about to address myself to that which is the next head about which I wish to say a word, and that is with regard to the polluting matter. I will ask your Lordship and the Commission to remember that at Question 9912 Dr. Tidy estimates it at 400 tons a day, and he referred to Röder and Eickhorn as having given valuable statistics with regard to the solid matter in ounces in fæces given as for a certain population; your Lordship will find statements with regard to that at Questions 9904 and 9909. Now I ask your Lordship and the Commission to observe that, although Dr. Tidy gave that evidence very early in the inquiry at Question 9912, we have nowhere had given to us, as far as I know, any estimate of the actual quantity of solid polluting matter sent into the Thames as against the 400 tons a day. I am aware that the 400 tons has been criticised, but we have had no alternative calculation; and I ought also to mention that the 400 tons do not include polluting matter from slaughter-houses, or cow-houses, or filth which might become noxious from kitchens, or laundries, or things of that kind; but it was entirely based upon sewage.

Now I know that Mr. Sorby did not go the full length to which I suggested that Dr. Tidy went; but I ask your Lordship to observe what the results of Mr. Sorby's analyses are, as given in his evidence commencing at page 23, where, in strong average sewage, he says, there are 1 per cent. of fæces, and of the solid residuals four times that amount, and you will also find a number of the results of examinations of samples in Mr. Sorby's microscopic examination, showing that there is a very large proportion of polluting matter in sewage which is not placed there, or does not get there simply by the human fæces, but gets there from some other source, partly from animals, and partly from other polluting things which take place, whether it be trades, or other things, which go on in houses, and which produce pollution.

Now I say again that nobody has pointed out the error which Dr. Tidy is supposed to have made, and nobody has put in upon the part of the Board an estimation of the actual quantities.

(*Mr. Norman Bazalgette.*) Would you kindly look at Questions 16,007 and 16,008, where Dr. Duprè puts it at 100 tons per annum? At Question 16,008 Dr. Duprè was asked, "There was some question of "that when Professor Way was here. I do not know "whether you greatly differ from him, but what "would be the amount of oxygen that you would "require to oxidise that?" and his answer was, "I "should say it is certainly less than 200 tons; we "get therefore only 100 tons a day against the "'400 tons of filth,' which Dr. Tidy calculated as "being discharged into the river."

(*Mr. Webster.*) I think that if my learned friend had observed more carefully he would have noticed that that is a reasoning back and not an argument based upon the actual production of sewage. I am aware of that, and I repeat that though it is criticised, and although the statement is made, yet there is no calculation which approaches the question in the same way as Dr. Tidy's does; nor is an error in Dr. Tidy's calculation pointed out anywhere. It is suggested to me, and I think it is properly suggested to me, that there is no calculation produced bringing out 100 tons, or anything like it; but I am aware that working back from the oxygen process a smaller quantity is mentioned. Sir John Coode says at Question 16,007, "I want to know at what particular "point the samples were taken which you say were "taken from the sewers." And Dr. Duprè's reply was, "They were taken either out of the main reser- "voir or out of the sewer which is discharging into "the river, so that the total amount of organic matter "out of the 1·68 ounces which actually goes into the "river and pollutes the river is only ·056 of an ounce "per head. From the one ounce of fæces about ·14 of "an ounce is also mineral matter, and I estimate that "the total amount of organic matter per head of "population which actually goes to pollute the river "is only ·916 of an ounce per head, which, taking "4,000,000 of people, comes to about 100 tons a day, "or 36,500 tons a year." I desire to say in connexion with this, that if the quantity of solids—polluting solids—be so much less (I at once say I do not accept, and those who advise me do not accept, Dr. Duprè's statement); but if it is so much less, so much easier would be the labour of anybody who had to consider how this amount of polluting matter had to be dealt with. We represent that it is greater; but still if it be so much less, as is pointed out, it would have a very great bearing upon the question which you will at some time or other have to consider as to the disposal of the sewage.

(*Mr. Bazalgette.*) If you will refer to Question 10,437 you will see that Dr. Tidy in cross-examination himself qualifies his 400 tons a day.

(*Mr. Webster.*) It is not a qualification of the estimate, but it is a suggestion that the calculation might be arranged in a different way; and if your Lordship will look at 10,433, Dr. Tidy says, "There- "fore, as far as that is concerned, if you like to take "it in that way, instead of putting it as 440 tons of "moist fæces, it is about 385 tons;" and although my learned friend Mr. Bazalgette says in one sense he qualifies it—he qualifies it upon the assumption put to him by my learned friend Mr. Bidder, upon some difference between German pounds and English pounds.

Now I pass from that, having, I trust and believe, made my meaning clear to the Commission, to the question of analysis, and I ask the scientific members of the Commission to observe the way in which this has been dealt with by the witnesses who have been called on behalf of the Metropolitan Works. Now, my Lord, there is a well-known process, the combustion process, which gives not only the relative, but I believe I state it correctly, the actual result as far as organic carbon and organic nitrogen are concerned. Dr. Tidy followed it, and so did Dr. Frankland—both of them. Dr. Odling admitted that it did give correct results; whether or not anything else might be afterwards determined is another thing, or whether or not, in addition to that, there might not have been room for supplemental experiment. But what I put as the fore front of our criticism upon the Metropolitan Board of Works dealing with this question by means either of the oxygen test or the albuminoid ammonia test is, that they have had under their hands that which would be for many purposes a much surer guide, at any rate, to check what they were doing, and they have not adopted it; and then I am justified, I think, in saying that if they have tried it, the results either do not conform to what they have found, or if they have not tried it, it was because possibly they said they thought their own process was better, or that the results would not agree.

Now, my Lord, ought they to have tried it? If the results shown by their processes have been consistent; if the results of their processes have really shown the same result, subject of course to little discrepancies, I agree that it would have been a strong argument in favour of the view that the albuminoid ammonia process and the oxygen process, though they

might not be actual positive tests of a particular sample of water, might be tests of relative purity. Take Teddington, for instance; if you analysed a sample of water by the albuminoid ammonia and the oxygen tests, Dr. Wanklin's method, and the other one,—and you found a certain standard; and you then took a water which you had every reason to expect to be worse than that, and you found it did come out worse by both tests—that to a certain extent would be taken to be a confirmation that the tests were reliable. It is, however, altogether the contrary. I hand in as part of my speech, and I ask you to allow it to be printed, a table showing, as far as they can be compared, the oxygen and the albuminoid ammonia tests taken by the Metropolitan Board of Works, and the results of Mr. Sorby's microscopic examinations. In every case the page is put, and the number of the sample; and I will ask you to consider what it shows.

*The Table was handed in, and was as follows:—*

*Put in by Mr. Webster, 11th July* 1883.

COMPARATIVE ANALYSIS of THAMES WATER as per EVIDENCE of METROPOLITAN BOARD.

The *italic* figures in the first and second columns refer to the pages in the Table of Analysis made by Sir F. Abel, W. J. Dibdin, Dr. Dupré, Professor Odling, and Dr. Voelcker; and in the third and fourth columns to the page in the report of microscopical investigation.

Taking the same water, it has been shown, in a variety of instances, to have improved according to the oxygen test, and to have got very much worse according to the albuminoid ammonia test. And this was no isolated instance; it was brought to the notice of the Commission by Mr. Lumley Smith in the cross-examination of Dr. Duprè in Questions 16,142 to 16,152. Your Lordship with perfect fairness indicated to my learned friend, Mr. Lumley Smith, that there might be some mistake about it. My learned friend, Mr. Lumley Smith, elicited this fact: that in a number of instances, not by any means exhausting the list or anything like it, but only taking five or six, the water which was shown to be getting better by the albuminoid ammonia process was shown to be getting worse by the oxygen process, or *vice versâ*; and your Lordship asked whether that showed anything more than that there was a mistake in the experiment. The witness clung to that straw and said, I think not. My learned friend, Mr. Lumley Smith, said, "We dispute the "Wanklyn process as being one to be relied upon. "We also dispute to a certain extent the oxygen "process as being good; and here you find that, if "you take two figures at random, they give opposite "results." (*Chairman.*) You have taken two specimens? (*Mr. Lumley Smith.*) And no doubt we could produce more. (*Chairman.*) But in a general way they tally, do they not? My Lord, they do not tally in a general way, or anything like it. Then the witness said, "The explanation is very simple. "The two processes—neither of them profess to give "the absolute amount of organic matter." I know they do not. "They must be compared with themselves, and not one with the other. You must not "compare the result by the oxygen process of different kinds of matter with the albuminoid ammonia "process, otherwise you will get discordant results; "you must compare the oxygen process right through, "and see what you get, and then compare the albuminoid ammonia process right through, and see "what you get from them all, and you will then find "the conclusions identical." My Lord, I submit to the judgment of the scientific members of the Commission that that is not so. I am instructed by Dr. Tidy and Mr. Baldwin Latham and others, who have examined it, that it is not true that the results are relatively identical, or anything like it. My learned friend, Mr Bidder, stated that they confirmed each other in the most remarkable way. I submit, upon instructions, that they do not do anything like it. They show that the water which according to one process is seen to be getting worse, according to the other process is seen to be getting better.

I would ask leave to remind you that this fact was called to the attention of a witness by Professor Williamson. Your Lordship having suggested, for the purpose of criticising the particular instances put, that it might be taken to be an error of manipulation. Professor Williamson said, "I think the discrepancy "of the figures can hardly be said to be a mistake in "either case, because each process determines something different from the other. They each attack "the question from a special side, and the quantity "of organic matter can only be judged by a sort of "guess work. Each determination may be perfectly "correctly made within very narrow limits of accuracy, and yet they may differ from each other, "so that each of them gives rather a sort of approximation to the truth than an accurate result." Now I invite the Commission to do this, because, though I am here as an advocate in my own person, yet the Corporation are not here as advocates in the ordinary sense of the word; we invite the scientific members of the Commission to examine these two tables. They were not put in parallel columns by the Metropolitan Board of Works. We have generally seen these things put in parallel columns, so that you might see the one compared to the other, and that we have done for them. I invite each member of the Commission to examine these analyses, and I allege as confidently as I am entitled to do, and as my learned friend, Mr. Bidder, alleged upon the other side, that so far from confirming one another in a pollution point of view, they show that the processes are unreliable.

Now let us approach the case from the point of view apart from results. Are our chemists right, who consider these processes unreliable, or are the Board right, who say they are reliable? Dr. Tidy said, in answer to a question, I know all about the oxygen process,—the particular process now adopted is one which I developed; but it is not reliable because of the evolution of hydrochloric acid. I do not know whether the Commission wish me to go over that, for I have no doubt I might make mistakes in it; but what I understood Dr. Tidy to say was, that in consequence of the evolution of the hydrochloric acid by the oxygen process which consists of putting in sulphuric acid and permanganate of potash, the result is that the test is not reliable. Now Dr. Duprè suggested a closed vessel. Here I am obliged to appeal to the scientific knowledge of the Commission, or to the scientific power of research of the Commission. I am instructed by chemists that doing it in a closed vessel would not eliminate the liability to error; and I am further instructed that they cannot understand how the doing it in a closed vessel would make any difference at all to the defect which Dr. Tidy has pointed out. I only put that to the Commission as part of my argument; you have on one side a gentleman who says he has done it, and on the other side you have Dr. Tidy, who says it is not reliable, and shows why he does not approve of it.

Now, in regard to the albuminoid ammonia process, would your Lordship kindly refer to questions from 15,777 to 15,814. Of course I am not going to read them; but every question will be found to be most important upon this particular matter. I will sum them up as I understand them, having read them more than once. They amount to this, that there are a number of things which get into the river perfectly independent of sewage which will produce albuminoid ammonia. I will ask you to refer first to Question 15,077, in which uric acid and urea and several other things are pointed to, and admitted by, Dr. Duprè to yield albuminoid ammonia, and yet not of necessity in any way connected with sewage.

(*Mr. Michael.*) Where do you say it is admitted by Dr. Duprè?

(*Mr. Webster.*) If you will kindly read questions and answers 15,777 to 15,814——

(*Mr. Michael.*) I have read them.

(*Mr. Webster.*) I submit to the judgment of the Commission whether that is not strictly accurate.

(*Mr. Michael.*) But that is the evidence of Mr. Dibdin, and not Dr. Duprè.

(*Mr. Webster.*) Quite so. I beg the pardon of my learned friend and of the Commission; the numbers of the questions and the facts were correct, but the name of the witness was wrong. Now I call attention to question 15,616, in which Professor Williamson pointed out the liability to error of the albuminoid

ammonia test, as compared with the other tests. My argument to the Commission, worth very little from me, but worth a good deal more when coming from the judgment of a competent gentleman, and submitted, as it is, to the judgment of competent gentlemen, is this: We know that the albuminoid ammonia and the oxygen tests are very unreliable, but that you must rely upon the combustion process, which will give you the actual amount of organic carbon, the actual amount of organic nitrogen, and, of course, the relative amounts. Now I shall have a word to say upon the matter of the albuminoid ammonia directly in connexion with free ammonia; but I pause in order not to lose the order in which the matter has been suggested to me. I ask the Commission to regard the value of this scientific evidence. I say that Dr. Tidy showed that at Teddington there was very little solid matter in suspension indeed. He showed that at Teddington the organic carbon was two parts per 100,000, that the free oxygen was two cubic inches per gallon, and that there was practically no ammonia. That I submit to the scientific judgment of the Commission is what Dr. Tidy showed as perfectly as it can be shown in the present condition of water analysis. Whether he is perfectly accurate in every detail he submits to the judgment of those who judge him in this matter; but that is the broad result of his evidence. Now, I venture to submit, taking his diagrams, and taking his tables, without denying that there are local ups and downs due to local causes, that, reach by reach, from Greenwich to Beckton the organic carbon increases, until you have at Greenwich three times the amount and at Beckton four times the amount that you have at Teddington. The diagrams are before you, but you will have this before you in print, and you will observe what I say. Concurrently you have a decrease of free oxygen, until at Beckton you have only half a cubic inch, as against two inches at Teddington. I say it by no means follows that the effective operation, from a purification point of view, of half a cubic inch of oxygen would be a quarter of the two inches, because, as Dr. Odling pointed out, as far as his experience goes, the effective operation decreases more than in exact proportion to the diminution of volume. Now, what do our witnesses say is the result of the evidence. That the oxygen was burning up the organic matter, the oxygen itself becoming exhausted, the organic matter still increasing. And I ask your Lordship and the Commission to judge whether this is not the correct result of Dr. Tidy's analysis, assuming the analysis to be correctly taken, and, of course, assuming (as I trust I have satisfied your Lordship) that the albuminoid ammonia and the oxygen tests are not reliable, viz., that, reach by reach, the increase of the ratio of organic nitrogen to organic carbon, whereas it was at Teddington 1 to 7·7 is at Vauxhall 1 to 6, at Greenwich 1 to 2·9, and at Beckton 1 to 2·5. We submit to the chemists on the Commission that that shows clearly that that pollution or alteration of the circumstances is due to animal and not to vegetable contamination.

I am not going over it again. I will admit, my Lord, that I am only, as it were, an educated parrot in this matter. I only want to bring the argument before the Commission; it does not commend itself, as I hope points of law would, because I have exercised a judgment upon it; but I have only endeavoured to grasp it, and to bring it to the minds of those whom I address.

(*Chairman.*) Bear in mind that you, if an educated parrot, are addressing, as far as I am concerned, an uneducated parrot.

(*Mr. Webster.*) Not altogether, my Lord; at all events, your Lordship will remember that there are birds in the nest who are educated, and who can assist you. I desire to formulate, as clearly as I can, the argument as I understand the evidence, and to indicate those points simply to the Commission.

(*Chairman.*) Would you, in plain English, which any bird could understand, tell us what it comes to. It comes to this, you say there is a greater quantity of putrescible (I suppose that is the word) matter in sewage than they allow upon the other side; is that so?

(*Mr. Webster.*) No, I go past that. I say in the river.

(*Chairman.*) I meant in the river.

(*Mr. Webster.*) I am not now dealing with the constituent parts of the sewage. I am dealing with the result of analysis of the water as it exists in the river itself. I will show you why I regard it as of considerable importance.

(*Chairman.*) If you are agreed as to the amount of putrescible matter in the sewage——

(*Mr. Webster.*) That simplifies the matter enormously.

(*Chairman.*) But you still might differ as to the quantity in the river.

(*Mr. Webster.*) Certainly.

(*Chairman.*) Because one side would say there is a greater mixture, and the other side would say there is a greater destruction.

(*Mr. Webster.*) No doubt; that the oxygen was burnt up to a larger extent than the other side would be inclined to admit. Now I was submitting that if these figures are right, which again I respectfully ask the judgment of the Commission upon, that the pollution or alteration is due to animal and not to vegetable contamination. At Question 16,554 I think your Lordship will find that, in substance, the deductions of Dr. Tidy from his tests, assuming his tests to be correct, and assuming the process to be correct, are agreed in by the other side. The fact of the matter is this, that if Dr. Tidy and Dr. Frankland are correct in saying that the combustion process is the more reliable, and the best guide to indicate to the Commission the actual state of things, the conclusions which I draw from the combustion process will not be disputed by the chemists upon the other side, and the state of things at the outfall, as compared with up the river, will not be denied by the chemists on the other side; but what they do say is, we think, that for this purpose the albuminoid ammonia and the oxygen test is the better test, and do not rely upon the combustion process. That is why I venture to attack the one method of examination, as compared with the other method of examination.

Now, concurrently with the increase of the ratio of the organic nitrogen to the organic carbon, your Lordship will remember the same diagrams showed a decrease of free oxygen, one line went up and the other line came down; and that was attempted to be met in this way. It was suggested that, because there was much more sea water down at the outfalls, therefore there would be less free oxygen in the constituents which had been examined. Now I must ask your Lordship to observe what Dr. Tidy has called attention to at Questions 10,221 to 10,225, and 10,217 to 10,218, and at 9872, in which he says that, as the result of many experiments, the quantity of free oxygen in sea water and in river water is, practically, identical; and that, therefore, the diminution of free oxygen, or the decrease of free oxygen, in the samples of water, cannot be due to the difference between fresh and sea water.

Now only one analysis has been given to rebut that statement; only one suggestion; and that is from that analysis taken at Southend. I think it was taken by Dr. Duprè, though I may have made a mistake about the name, but I think the Commission will find it is from a sample taken by Dr. Duprè at Southend. Now whether a Southend sample, which might be more or less contaminated by sewage, would be a reliable guide, I submit to the Commission as a matter of doubt; but I rely upon that which was put by Dr. Tidy in the forefront of the argument, that, in his judgment, the free oxygen in the sea water was, for these purposes, identical with that in the river water, and in that Dr. Odling agrees with him at Question 16,471. Now I do not say that the purifying power of the water varies exactly with the free oxygen, for

11 July 1883.

at Question 15,572 Dr. Odling practically shows that if you reduce the quantity from two cubic inches to half an inch it by no means follows that the purifying power of the water from the oxygen point of view is a quarter of the larger quantity.

I have brought before your Lordship's mind, and I trust before the mind of the Commission, such criticisms upon that part of the chemical case, as I think it right to present to you. There are two or three minor matters, but still matters of importance, which I will notice as I pass on. One is the importance of the free ammonia, and here I may profess (having a little smattering of knowledge upon this part of the subject) that I did expect to find that when they produced the albuminoid ammonia test, they would have told us what the quantities of free ammonia were, because I am told that they must get rid of the free ammonia in order to determine the albuminoid ammonia; therefore it is knowledge that has passed through their hands, so to speak, or which has passed under their attention. Now, I would ask your Lordship to refer to Question 9870, where Dr. Tidy is asked "You have told us that in the upper Thames "water the ammonia is nearly nil. (*A.*) Nearly nil. "(*Q.*) And in sea water it is also nearly nil? (*A.*) "Yes, in sea water also it is nearly nil. (*Q.*) That "will be of importance when you come to try to "trace the sewage? (*A.*) It will; the question of "the ammonia will become an important one. Then "another thing to be noted is the very small quantity "of nitrogen as nitrates in sea water." Your Lordship will find upon the table, and the chemical members of the Commission will find upon the table, put in by Dr. Tidy, an analysis of free ammonia put in for each sample. Now will your Lordship turn to Dr. Frankland's evidence; at Question 10,748 he is asked "But we have heard that ammonia is very "evanescent," he had been referring to the ammonia test above, "does that qualify what you have said with "regard to the value of the ammonia test," to which he replied, "Yes, it qualifies it in one direction, as "I think I mentioned upon the last occasion. "Where you find this excess of ammonia it is "positive evidence of the presence of sewage, but if "you do not find ammonia it is not positive evidence "of the absence of sewage; the ammonia is "evanescent, it rapidly disappears;" and I am instructed, my Lord, and I put it to the Commission, that to have ascertained the quantity of free ammonia in these samples taken, there being admittedly little, or I would rather say, no free ammonia in the Teddington water, and none in the sea water; and there having been put in a table by Dr. Frankland and Dr. Tidy pointing to this; and there having been no cross-examination of them as to whether the ammonia test was not most important, I think that if it be true that in ascertaining the result by the albuminoid ammonia process, you would get the amount of the free ammonia, it would have been important to have that information given to the Commission, if Dr. Tidy's evidence was going to be disputed.

(*Chairman.*) Were any of the witnesses asked that.

(*Mr. Michael.*) There is a column for free ammonia in our analyses.

(*Mr. Webster.*) It is only in Mr Dibdin's, and I think I may say that it has never been used. I am told that it does occur in some of the samples of Mr. Dibdin's, it does not occur in Dr. Duprè's.

(*Mr. Michael.*) I have Mr. Dibdin's tables before me.

(*Mr. Webster.*) But I am told it is not in the other one's.

(*Chairman.*) That is a somewhat serious question, because you appear to suppose that these gentlemen knew something, and suppressed something.

(*Mr. Webster.*) No. I do not wish to put my case a bit higher than I ought to do. These gentlemen are wedded to the albuminoid ammonia and the oxygen process. I say that there are known tests which they ought to have used, whatever their value may have been, to have checked that which they thought was a reliable guide.

(*Chairman.*) Was anyone asked as to it.

(*Mr. Webster.*) I am not sure, my Lord.

(*Mr. Michael.*) No, there was no examination about it.

(*Chairman.*) Mr. Michael has the advantage of you, because he is certain.

(*Mr. Webster.*) It was never used.

(*Chairman.*) I do not know whether the scientific members of the Commission will understand the value of the point, I confess I cannot.

(*Mr Webster.*) I cannot myself profess to understand it.

(*Chairman.*) I cannot help thinking it strange that the chemists were not asked it. At *nisi prius* one would say of course they did not dare ask it.

(*Mr. Webster.* I am not conducting this case, as your Lordship knows, in a *nisi prius* manner. The only criticism I want to found upon it is that this is an additional reason for not relying on, what I have described as the inconsistent results of the albuminoid ammonia and the oxygen process. It is not as if all the Commission were obliged to be only in your Lordship's position of judging of the matter as a question of fact.

*Mr. Michael.*) If your Lordship will kindly turn to Question 10,748, Dr. Frankland, their own witness, says it is of no importance; it is no indication whatever.

(*Mr. Webster.*) I read that a moment ago to my Lord Bramwell and the other members of the Commission.

(*Chairman.*) He says, "If you do not find it, it is not positive evidence of the absence of sewage." What you say is, that these gentlemen must have found it, and have not noticed it.

(*Mr. Webster.*) Yes, that they could have found it; and I am instructed that they must have found it. That they could have found it, if Dr. Tidy is instructing me correctly, is clear; of that the members of the Commission must judge.

(*Chairman to Dr. Duprè.*) Did you find it?

(*Dr Duprè.*) Certainly; but there were already so many figures, and we thought it was really no positive indication, not so valuable as the albuminoid ammonia test; and in order to avoid too great a number of figures, we left it out. We found it in every case.

(*Chairman.*) You did find this free ammonia?

(*Dr. Duprè.*) Certainly. There are many things left out in order to keep the tables clear.

(*Mr. Webster.*) I only call your Lordship's attention to it to show that you ought to hesitate before adopting the view presented by the Metropolitan Board as to the chemical part of the case. I was only doing my duty in reference to Dr. Frankland's positive evidence with regard to it, and to Dr. Tidy's statement that it was of importance, as to the deductions which they drew from the ammonia. If I am right in saying that the albuminoid ammonia is not a reliable test, nor the oxygen either, it does make the free ammonia of the more importance.

Now, upon the microscopic evidence. We have Dr. Tidy and Mr. Lionel Beale telling your Lordship that which was new to the scientific world, I believe, namely, that the spirals and the amorphous matter are undoubted indications of the constituents of sewage, and the witnesses said, without attempting to do it quantitively, that they considered there was an undoubted increase from Chiswick to Crossness. Now, my Lord, Mr. Sorby, who for the first time has evolved a theory of quantitative microscopic analysis by means of measuring the field which is examined, assuming his plates are placed at the same microscopic distance apart in each instance, has been able to say, not that there are less of these particular things, but that there are other counteracting influences which, in his judgment, destroy any baneful effect which might be brought about by the presence of such things. Now, it is admitted that Mr. Sorby's method depends upon the skill of the operator. You will

recollect the question I put to him, and I trust the Commission will very, very carefully consider how far they will be justified in acting on these facts and conclusions derived from Mr. Sorby's examination. I am instructed that such an operation is one of exceeding difficulty of manipulation as was admitted by Mr. Sorby, and it must of necessity involve a considerable liability to error, and probably the existence of a good many errors, and it cannot be relied upon for the purpose of forming a safe guide.

My Lord, there is one criticism which I can apply to this. I pointed out, and I remember Sir John Coode pointing out, that I was well founded in my observation, that Mr. Sorby made the water lower down the river materially better than it was near London Bridge; and there are numbers of instances in his cross-examination showing a much worse water higher up than lower down. Now, whatever view you may take with regard to what was the state of matters between Woolwich and Purfleet, which is the area I am coming to directly, I shall submit to your Lordships, upon the evidence, that nobody pretends that the same thing had been even possibly complained of above Greenwich. Your Lordship said more than once, We are all of opinion that the evidence of real nuisance (I am not speaking of the exceptional nuisance) is certainly below Greenwich. And I ask your Lordship to remember that nobody, until Mr. Sorby came, ever suggested viz., that the same kind of appearances as were said to have taken place, truly or falsely, below Barking and Crossness, ought, in fact, to take place at London Bridge, if the story were true. And what I think would be a not unfair commentary in addressing a jury upon this matter, would be, that if Mr. Sorby's allegation is true, it is inconceivable that everybody should be practically agreed, that whatever it may be chemically, and whatever it may be microscopically, the water at London Bridge is practically better than the water down below.

(*Chairman.*) I think we all noticed that at the time.

(*Mr. Webster.*) I ask your Lordship, when you and the Commission come to deal with the matter, to remember that the microscopic evidence is far more properly dealt with by Dr. Tidy and Mr. Beale, as corroborating the qualitative results and not the quantitative results, than it is by Mr. Sorby, in the very learned and interesting way in which he dealt with it.

I am glad to tell your Lordships that there are only two other small matters which I have to notice upon the scientific part of the case, and I will pass them over as shortly as I can. One is with regard to the actual origin of the muds. At Question 10,692 Dr. Frankland pointed out that the muds of the upper Thames were chiefly vegetable; at Question 10,693 he pointed out that the muds of the Lower Thames were chiefly animal. Now, I am not upon the question of pollution or not, for the moment, I am only following out the general line of thought, whether it is contamination by animal matter as distinguished from vegetable matter; and I was amused by my learned friend, Mr. Bidder, trying to catch your Lordship with the argument, that because some fishermen said there were worms, and some that there were not worms, that the worm question had nothing to do with it, but the real fact was that these people did not possess the power of discrimination between worms, except as regarded worms for the purpose of bait. Dr. Tidy is, however, competent to deal with it, and I ask you to consider his evidence upon it.

Now, would your Lordship bear in mind a point referred to and relied upon by Dr. Tidy with considerable emphasis, which followed upon a question put by the Commission. If your Lordship will look (I will not read it) at Question 10,001, your Lordship will find a suggestion made by Professor Williamson to Dr. Tidy. I put it in the language given to me, which, I think, is correct, as to whether the sulphates of sea water would not become reduced to sulphides by the organic matter of the sewage. Dr. Tidy stated that it was a matter of considerable importance, and that he was going to deal with it presently; and at Question 10,676 your Lordship will find he puts it distinctly. He refers to the chemical action suggested for his consideration by Professor Williamson, and agrees entirely with the view put forward which, he said, he had previously considered, and to which he attached importance. It all has an important bearing upon the action of these elements upon the water into which the sewage is turned. 11 July 1883.

Now, I will only notice in passing that, practically speaking, the only remedy which the Board rely upon is, first, the oxidation of the sewage by the oxygen of the water, and, secondly, the existence of a large amount of invisible water which Mr. Law has discovered. I do ask your Lordship to kindly consider the questions which I put to Mr. Law as to where the water was to come from which was to produce the invisible underground supply, and also the number of square miles it would require; and I think I pointed out that the figures he quoted from Dr. Priestwich's book were figures prepared from an entirely different standpoint.

(*Chairman.*) I think Mr. Law admitted that he could not swear that the whole of it did not find its way out 1,000 miles into the Atlantic, except that he pointed out some particular channels in the chalk as to which that could not be so.

(*Mr. Webster.*) That was so. Now I have, without, I hope, occupying more time than I ought to have done, called attention to the great matters of principle with regard to the samples part of the case. I will only say on leaving it, that if your Lordship will kindly refer to certain comparisons made by my learned friend Mr. Bidder, the multiplication of quantities or numbers of grains by the amount of organic pollution, and things of that kind taken from the tables, your Lordship will find that he was in all instances he quoted, taking waters of different days, and comparing them together; and further than that he was taking in his Barking instance 4·016 which was the figure he quoted, as an instance of a particular sample at Barking; whereas upon the same table by the same chemist, next door to it, were two samples taken upon the same day and at the same time, showing instead of 4·016, 7·57 in two instances. I only call attention to this for the purpose of submitting to the judgment of the Commission, that they must not take, and they would not take, without examination, my learned friend Mr. Bidder's calculation; but I am instructed that if you examine them they are comparative calculations which do not refer to one another, but refer to different days, and should be taken, if taken at all for the purpose of comparison, with the samples taken upon the same day, and at the same part of the river. Now I come to the question your Lordship has put pointedly to us more than once, "After all no matter what your doctors say, "Does it or does it not stink?"

(*Chairman.*) Has any question of this sort been suggested, that if you took a given part of the sewage and a certain number of parts of unpolluted water and shook them violently together, the sewage would be much sooner burnt up or destroyed, than if you were gently to pour the sewage into the vessel.

(*Mr. Webster.*) It depends upon the chemical combination. I am not chemist enough to answer your Lordships' question.

(*Mr. Michael.*) It would be so.

(*Chairman.*) If you have a large body of sewage coming out at once, it flows in a marked stream down the river, as we saw, and it reminded one a little of the Rhone and the Arve, where the Arve continues unmixed with the Rhone for a long way, and until the mixture is complete the oxidizing does not take place. Does not that make the scientific evidence, I will not say comparatively of less value, but more uncertain.

11 July 1883.

(*Mr. Webster.*) May I be allowed to tell your Lordship how I regard it. Your Lordship has had put before you on both sides a mass of scientific evidence and scientific facts. The Board of Works come here in the discharge of a public duty, and they tell you that the existing system is either as good as it can be or not so bad as to call for a remedy under any circumstances. The only reason why I am referring to it is to prevent your Lordship and the other members of the Commission, if I can do so, from without due consideration, reporting something which would apparently prejudge the question from a scientific point of view; and I should like now to occupy your Lordship for a little time with regard to what the evidence really shows.

Now, I confess, though I have not had the advantage of perusing my learned friend Mr. Bazalgette's notes (my learned friend, Mr. Bidder, told us how much he was indebted to him in the matter), they must have been notes most cleverly and cunningly prepared, for they enabled my learned friend Mr. Bidder to steer clear of some of the most remarkable difficulties of evidence that it has ever been my lot to consider. My Lord, a great quantity of this evidence was taken a year ago; it has passed away to a certain extent at any rate in detail from your minds. My learned friend, Mr. Bidder, told your Lordship on Monday, that a particular witness, a witness of the highest respectability, as I will show you presently, and having the fullest opportunity of judging, must have been mistaken, because he had made a statement with regard to the comparison between the water in the year 1858 and the water in the year 1881, which could not be believed. I will show your Lordship, and I confess, except that I know how much he has to do, I was surprised that it did not occur to my learned friend Mr. Bidder to see how many people absolutely corroborated that, both chapter and verse, from independent sources and independent evidence, from statistics and entries made at a time when they could have had no knowledge whatever of what that man was going to say.

Now what I am going to put before your Lordship is the issue, which I say we have proved. I say we have proved this: that not at all times of the year, of course not, else this Commission would have been sitting years ago, but that after a continuance for a month or six weeks of serious hot weather, there does rise from the mud, and there do exist in the water black masses which break up, which give off noxious gases, which are most offensive to the individual who comes in contact with them, and which have had effect upon health. My Lord, I, at any rate, have had too much experience to ask your Lordship even to hear me upon an issue, unless I thought I had substantial evidence to support it, and I am not going to contend before the Commission that we have proved at present a serious injury to health. Your Lordship indicated, I do not think in any way prejudging the question, if I may say so, to my learned friend, Mr. Bidder, that you were all pretty much of that opinion. Now I recollect a very clever answer which was made by a lady to my learned friend, Mr. Benjamin, when he was cross-examining her as to an alleged nuisance. She said, "Well, if you call a "nasty taste in your mouth, and a feeling of not being "well, and not being able to do much,—a nuisance, "that is what we experience, not that we have called "in a doctor." Now, I say, it has already amounted to that which in that point of view does constitute a serious nuisance.

(*Chairman.*) I thought you were going to call attention to the gentleman who gave that evidence as to the state of the water in 1858.

(*Mr. Webster.*) I am coming to that directly. Now what occurs in bad times produces, as it is alleged, a feeling of *malaise*, and to a certain extent of nausea, not which does affect the health at present, but which might become very much more serious. Now you were invited to go any day you liked and smell it. My learned friend, Mr. Bidder, asked you, Did you smell anything when you were there? We know very well that if the river were always as it was when you went down, this Commission would never have been asked for. I ask you as judges of the facts in this case, to say, that unless there is the most distinctly, deliberate perjury in this matter, there has been positive evidence of facts. Witnesses corroborating one another as to this state of things to a far greater extent than my learned friend Mr. Bidder will admit; he has called it mistake; he has called it exaggeration, we will see in a moment or two whether it has been so or not.

Now I disagree here. I leave that to my learned friend, Mr. Beaumont Morice, the evidence of men like fishermen and lightermen, who may exaggerate, or who may be mistaken, but with this one observation. It is not because my learned friend, Mr. Bidder (as Sir Benson Maxwell pointed out to him at the time), put the conversation into the witness's mouth, and that witness said, that that conversation took place, that your Lordship and the Commission would entirely disregard it; that is a very useful way of suggesting a conversation in cross-examination; but I do not think in a matter of this sort, that you would pay much attention to it.

(*Chairman.*) I do not recollect the particular case to which you refer.

(*Mr. Webster.*) I will take the case of the witness Cobb. My learned friend Mr. Bidder has over and over again reverted to it. He was asked in effect. You were present at the conversation at the "Golden Anchor." Sir Benson Maxwell pointed out to him, I think it was in this case, that he was putting the conversation into the witness' mouth, and my learned friend Mr. Bidder has always assumed that the whole of these fishermen's evidence was got rid of by means of this fishing and clever cross-examination.

(*Mr. Norman Bazalgette.*) You will find it at Questions 1356 to 1370.

(*Mr. Webster.*) I will take Question 1353. Cobb was asked "Who asked you to come here and give "evidence?" To which he replied, "A gentleman "who comes from Greenwich, I believe. I do not "know his name. (*Q.*) Did you have a meeting "about this a week ago? (*A.*) He asked me if I "would collect as many fishermen as I could "together, and I did so. (*Q.*) Did you have a "meeting at a public-house. (*A.*) We did. (*Q.*) "What was the name of the place. (*A.*) The "'Golden Anchor.' (*Q.*) Was that the anchor you "lost. (*A.*) No. (*Q.*) One you often hanker after, "I dare say? (*A.*) No doubt." This is all very amusing and funny. Then he is asked, "How many "of you were there," and his answer was, "About a "dozen of us. (*Q.*) Who were there? (*A.*) I do "not know the gentleman's name, but he is here. "(*Q.*) Did he make a speech." Now there he is not right, for the witness says, "He asked us to "collect the fishermen, and he asked me in par-"ticular, as I was the oldest fisherman there, to "collect the fishermen together, to see what we knew "about it. (*Q.*) After that, I hope he behaved "handsomely to you? (*A.*) We had several pots of "half-and-half. (*Q.*) After having had these pots "of half-and-half, did he address you on the subject? "(*A.*) Yes. (*Q.*) He told you what he wanted you "to do,—to find fault with the sewage? (*A.*) Yes. "(*Q.*) Did he ask you how far you could help him? "(*A.*) Yes, he did so. (*Q.*) He asked you if you "could say the fish had gone out of the reach? "(*A.*) Yes, he did. (*Q.*) He asked you if you "could say that you had seen the sewage run down "the reach. (*A.*) Yes." It is the commonest common jury trick that ever has been done.

(*Chairman.*) As you have been reading that I was anxious to see if I was in the chair, and I find it was not myself, but that it was Sir John Coode. You have heard me before, a good many times, but I have always said, "You are not cross-examining, you "are putting words into the man's mouth, and asking "him if he agrees with them." Such evidence as

that is not worth a fig. A poor man sees a gentleman of considerable position, while he is only a fisherman.

(*Mr. Webster.*) And he would naturally accept the proceedings very much as they were put to him.

(*Chairman.*) I am sure that the witnesses called on both sides are respectable people, and that the intention of those who call them is that they should tell the truth, and it is quite possible that Cobb, under the genial influence of a pot of beer, made it a little stronger than it was, but you would not on that account refuse to accept it altogether.

(*Mr. Webster.*) No, I would not say so. I would say it was exaggeration; but because my learned friend Mr. Bidder performs that not very wonderful feat of putting an entire conversation into a man's mouth, I think he is not entitled to say that the evidence is worth nothing. Now, much of this evidence is given by men who are capable of giving your Lordship evidence of value. I will ask your Lordship to refer to Dr. Jessett's evidence, at Question 4460, on page 22, where he was asked, "Do you "still think that the sewage passing down the river "is likely to exercise an evil effect? (*A.*) I have "not a doubt of it. I myself have been yachting. "Only last summer I went out yatching, and kept "coming up with the flood tide, and when the tide "came up there were large masses of sewage, as "large as the table in front of me, floating about, "and ladies on the yacht were sick, and could not "eat their tea on account of the atrocious smell from "those masses of sewage that were floating about in "the river, and that was on the flood tide, and not on "the ebb." He is the medical officer of health for the Erith district. Now that gentleman may have a strong feeling about it, but nobody can say that that is imagination. Here is a medical man saying that there are masses, not in the whole of the river, but floating about in the river. Those are masses, they are not smells from the factories, but visible masses.

(*Chairman.*) Do you go to the extent of saying that the evidence shows a nuisance to people on the land?

(*Mr. Webster.*) No; upon the land away from the river as distinguished from the very boundary of the river, not, but I think I put a question to Sir Joseph Bazalgette, for which your Lordship a little reproved me, by asking whether Sir Joseph Bazalgette was the judge of that, and not the Commission. But I submit respectfully, that to the port London this is of very considerable importance, because there is a very considerable floating population, and a considerable number of vessels coming up to the port of London.

Now I will not refer to Dr. Frankland and Dr. Tidy again, except to remind you that Dr. Frankland said that in his judgment distinctly the river was getting worse.

(*Chairman*). I do not think Dr. Tidy did that.

(*Mr. Webster.*) Dr. Tidy spoke to seeing the sewage bubbling up.

(*Chairman.*) Would you give me the reason why it should get worse—the population gets larger, but it is only in that sense?

(*Mr. Webster.*) I should consider in the first place that the growth of population is one cause. I should consider again another cause is that the banks of the river became more foul in their deposit, and upon that I desire to remind you of the evidence, which I did not hear alluded to in my learned friend Mr. Bidder's speech, of the foul condition of anchors and cables, and nets and things of that kind which are brought up from the bottom of the river: it has not been referred to at all, and yet people of undoubted respectability have spoken to the fact.

(*Chairman.*) And having to wash the gravel and things that they bring up.

(*Mr. Webster.*) Yes, and having to boil the clothes of a large number of the bodies of those who were brought out of the river after the "Princess Alice" accident in order to get rid of the foul smell.

(*Chairman.*) What do you say as to Sir Frederick Abel's evidence.

(*Mr. Webster.*) I will deal with that at once. Sir Frederick Abel is a gentleman of the highest position, and of course a friend of a great many in this room. I am glad to say that I also have the honour of his friendship. He goes out to the terrace at Woolwich to get his fresh air. Such is what he goes through in the course of the day, that it is fresh air to him when he goes out and takes his walk there, and I think a man is justified in saying, and I shall refer to it again when I comment upon the remarkable absence of witnesses upon the part of the Metropolitan Board of Works as to this fact. I say I cannot help thinking that when Sir Frederick Abel has been out there for fresh air when the sewage at Woolwich was bad, that the frightful smells that have been evolved in the process of the chemical and gunpowder experiments there, which he has gone through for so many years have seriously impaired his nasal organ; and I certainly should not like to accept as a test of the smells which come from the sewage, the evidence of a gentleman accustomed to the frightful smells which comes from the detonation of bad gunpowder and other explosives.

(*Chairman.*) Sir Frederick Abel says, if you go into the sewage stream you smell it for 1,000 yards, and after that you do not smell it unless you shake it up in a bottle, and after about another mile you cannot smell it any way.

(*Mr. Webster.*) But he goes further than that—he describes it, when he is only a few yards from the stream itself, as a "faint whiff"—that is when he is 50 or 60 yards away; and I cannot believe in the nasal organ of anybody who, at that proximity, describes the smell of the outpouring sewage as a "faint whiff."

(*Chairman.*) I want you to couple that with the evidence of Captain Burstall; he says he smelt it at Woolwich. Now we have had it proved by the Metropolitan Board of Works that undoubtedly when the tides are making, it does come back to Woolwich. According to Sir Frederick Abel, that is three miles from the outfall, and it ought to have ceased to smell by that time whereas Captain Burstall says it does smell. Now, we have evidence that there is sewage sent out nearly opposite Woolwich from the East Ham outfall, and we have this, that intermediate between the two places, Woolwich and the Barking outfall, there is a training ship which one would think would hardly be put where there is such a nuisance as you mention. I refer to the training ship "Cornwall." Now I know there are not many people living between the two places, but I do not think there is a single witness who has occasion to cross the river who complains of the smell. It looks a though it might be argued that the smell which Captain Burstall smells at Woolwich is not the smell of the outfall.

(*Mr. Webster.*) I will ask your Lordship to let me bring before you a few answers to show that it cannot be disposed of by anything of the kind which has been suggested. Now, the age and the experience of Captain Burstall being admitted by my learned friend Mr. Bidder, all he can say is that his nerves have destroyed his judgment. Now, I would ask your Lordship to look at the way in which Captain Burstall has given his evidence at Questions 6423 to 6426. He says "In cold weather you may get the mud up "from the bottom of the river almost opposite the "outfall, and you cannot smell it. In cold weather I "have got the mud up from the middle of the river "opposite the sewer, and in many other places, and "you cannot detect any smell from it." Now is that the evidence of a man who is unable to exercise his judgment and who simply comes up and smells the river, and, though he lives upon the river, yet, from a nervous fear, concludes it is all sewage? I ask your Lordship how can you account, not for this only, but for a great deal more, to which I will call attention in a few minutes? Unless you can dispose of this by saying it is a mistake, a thing for which some other origin can be traced, there must be some absolute ground for it in matter of fact.

11 July 1883.

Now, would you refer to the evidence of Mr. Lewis, as to whom my learned friend Mr. Bidder did not hesitate to say that he must be mistaken, and did not refer to the remarkable corroboration there is of his evidence. Mr. Lewis begins at question 5020 and he refers to the year 1880, and I ask your Lordships to remember what I say, his evidence is that, whereas in 1858 the river was, as a whole, a stinking sewer, in 1880, there were in patches that which was matter of the same kind. Some of the Commission may remember what the condition of the river was in 1858; my learned friend Mr. Bidder referred to his personal experience upon one point, and perhaps in this tribunal I may say that, happening to be taken by my father in 1858 over the new Westminster Bridge works, which were then being constructed, I remember that the river then running as a black sewer and was offensive to the last degree. Now I ask your Lordship to notice the date. This is the port sanitary inspector, and speaking of July 1880 he says, in answer to question 5,020: "It was in "black patches, it seemed like floating mud as it were, "in black stinking matter. As soon as you touched "it, it tumbled to pieces. This black floating stuff "on the water seemed as if it came from the bottom, "as though it had been drawn up by the heat. "(*Q.*) It seemed to have come up in patches from the "bottom, and then it floated on the top. (*A.*) That "is so. (*Q.*) Did it break up then, or did it break "when it was touched. (*A.*) It broke up at the "slightest touch. (*Q.*) But the patches might be the "size of a table, or they might be the size of a room; "what was their size. (*A.*) They were all kinds "of shapes, the large ones would be about six to "eight feet in length, and the small ones would be "about half that, and their breadth would vary from "three feet to six feet, speaking roughly. (*Q.*) Did "they have the appearance at all of common Thames "mud. (*A.*) Oh no, not at all. (*Q.*) Was there "anything else about it, was it offensive in any way? "(*A.*) Very offensive. (*Q.*) In what way? (*A.*) "There was a fearful stench with it. (*Q.*) This you "say was in July 1880; did that last for any consi-"siderable time in 1880? (*A.*) It lasted nearly the "whole of the month of July, up to the early part of "August, and then it came on to rain, and there was "a thunderstorm, and down went this thick stuff, and "it did not appear again during the wet season after "the rain came. (*Chairman.*) Never again? (*A.*) "Not then. (*Mr. Lumley Smith.*) Had that occurred "before within your knowledge? (*A.*) In 1858." Then I want to refer your Lordship to question 5,041, because this shows that I was correct in my estimate which I had formed of the man. He was asked "In "July 1880 these patches did not pervade the Thames "for the whole of the year; but in other parts of the "year have you noticed anything in the river at all; "has there been any change in the character of the "river? (*A.*) Yes, after, say, 1864, the river seemed "very good, and during these last six or eight years, "speaking roughly, the river has assumed rather a "bad character, it has been getting gradually worse "than it was prior to that time. (*Chairman.*) What "do you mean by 'getting worse'? (*A.*) Take the "northern outfall or the southern outfall; the river "there assumes a very black appearance, and smells "very badly. (*Q.*) Then what you mean by its "'getting worse' is that it is getting blacker and "smells worse? (*A.*) Yes. (*Sir John Coode.*) Within "the last six or eight years? (*A.*) Yes. (*Mr. Lumley "Smith.*) Has there been any recurrence of this "appearance of the patches since July 1880," and so on. Then I should refer you to question 5032 where the witness was asked: "In 1858 do you remember "anything similar to what you saw in 1880? (*A.*) "There was a greater amount, and it lasted for a "longer time (*Mr Bidder.*) Was it worse? (*A.*) "Yes, because these patches extended the whole width "of the river, in fact then it was a black ditch? "(*Q.*) The same same sort of thing as occurred in "in 1880, but much worse? (*A.*) Much worse." Now that was what was referred to by my learned friend Mr. Bidder on the last occasion, and stated to be a mistake; he said it must be a mistake, because he was referring to Cherry Garden which is up at Rotherhithe, and it was said he must be wrong. Would your Lordship kindly oblige me now by referring to Captain Marsden's evidence at question 5355.

(*Chairman.*) But Mr. Lewis says that was in a different part of the river.

(*Mr. Webster.*) In 1858 he says the river was like "one whole black ditch."

(*Chairman.*) That was in a different part of the river; I think Mr. Bidder said there must be some mistake because he found the same thing in 1858 as he does now; whereas the witness says it is a different part of the river, though in a part where it might have been from a similar cause.

(*Mr. Webster.*) But that is not my learned friend Mr. Bidder's only criticism. His criticism was that because in 1880 these black patches existed up to Cherry Gardens, which is up at Rotherhithe, the witness must have been wrong: he must have been confusing his recollection; and my learned friend put it most forcibly to you upon the point.

Now, would your Lordship kindly refer to Captain Marsden, the harbour master, who could not have known what Mr. Lewis was going to say. Reminding you, that the period spoken to by Mr. Lewis, the sanitary inspector, is July 1880, at question 5356 Captain Marsden was asked, "Have you notes of those "observations with you? (*A.*) Yes," and the witness thereupon handed in a paper. Now, this is an extract from a journal entered at the time by the harbour master, a most respectable man, a man utterly beyond the reach of pots of beer influence, or anything of the kind, and I ask you to read it: "July 24th, 1880. "Attending a launch at Messrs. Edwards, Milwall, "three-quarters flood, the water was very foul, and "off Cubitt Town the stench and state of the river "was very bad, a black slimy appearance being on the "water. This was the worst state I ever saw the "river in." Your Lordship knows probably that Milwall is above Greenwich, and is a short distance, not very far below Cherry Gardens. Now, I refer to other entries with regard to the year 1880. They are entries, as I say, made at the time, and this witness speaks distinctly to the horrible smells. I am reading from his answer to question 5384, where he speaks of the black slimy appearance of the water in the river, and says it was in the worst state he ever saw the river in. That is a contemporaneous remark mode at the time when he refers to what he believes to be sewage. And this I put forward as an independent corroboration of Mr. Lewis' statement, to which not a word of reference is made by my learned friend Mr. Bidder; and yet my learned friend Mr. Bidder comes in and asks you to disbelieve Mr. Lewis because he said the river at Cherry Gardens was like the river had been in 1858 higher up; he said it had been worse in 1858 than it was in 1880, and he is corroborated by an independent man.

Now, would your Lordship kindly look at the evidence of Captain Fitzgerald of the Royal Navy. Here again, my Lord, is a staff commander of the Royal Navy and harbour-master of the Central Station on the River Thames, continually up and down the river, and will your Lordship kindly look at his diary, taking first that which relates to the year 1880, which, as printed before the Commission, goes all through July 1880. It begins on page 2 from question 5505, and I will ask your Lordship to refer to the entry of the 21st of July which is at No. 5518: "River water "this day fairly clear on surface, but filthy and "stinking underneath, every steamer leaving dis-"coloured water in her wake. Immediately above "Leather Bottle Point the water was nearly black at "the last quarter flood, covering a surface of nearly "a mile." But what is of more importance for this purpose is to show your Lordship the condition of the river upon the 26th July 1880. At question 5530, this has reference to July 1880, because the diary for 1878 was handed to my learned friend Mr. Bidder,

and he is still reading on consecutively through 1880, the entry is, "At low water to-day the river from "Bugsby down was choke full of sewage." Now, does your Lordship know where Bugsby is? It is above Cherry Gardens.

(*Chairman.*) He says that is at low water, where on earth does he suggest the sewage had come from?

(*Mr. Webster.*) From the water below and from the mud. Now, Busby's Hole is endeared to me by many collisions. I speak from a large recollection of it in the Admiralty Court.

(*Mr. Michael.*) No, I beg your pardon, it is considerably below Blackwall.

(*Chairman.*) There is a Bugsby Hole somewhere.

(*Mr. Michael.*) That is exactly the point of the discharge of the West Ham sewage at low water.

(*Mr. Webster.*) Then I withdraw what I have said about Bugsby's Hole. Now these entries go from Crossness right up, and they do point to the same state of things existing far up the river and low down, namely, offensive smells given off by the mud. I thank your Lordship for the question you put to me just now, for it enables me to accentuate what I say. It is not only the surface of the water but the gases given off from the mud at the bottom of the water.

(*Chairman.*) Nothing would persuade me that Captain Fitzgerald was not endeavouring to tell us the truth, he is a man of intelligence and observation; but how on earth he could have smelt the sewage except that he might have smelt the mud banks at the side, I do not understand, and I do not understand that the witnesses do smell the mud banks at the side.

(*Mr. Webster.*) That he does?

(*Chairman.*) That anybody does.

(*Mr. Webster.*) I could call your attention to several of the witnesses who say that it is just as offensive as the water is, that it gives off gases and bubbles in the same way.

(*Sir John Coode.*) I understand your contention to be that the evolution of gas from the mud breaks up the mud and causes it to rise to the surface.

(*Mr. Webster.*) I understand that gas is given off by the mud, and I understand that there rise to the surface what are called floating gassy masses, which are in themselves offensive, and which are apparently composed of some amorphous substance, which disappears at a touch. I am obliged to my learned friend Mr. Michael for correcting me in saying that Bugsby's Hole is below Blackwall, he is quite right, but I observe at question 5527 this gentleman says that upon the 23rd July 1880, that is the day before the independent evidence from Cherry Gardens, his entry is as follows: "Water during the whole flood "heavily charged with sewage matter from side to "side, nearly black in some places, and the river, "even at high water, above Greenwich, full of sewage "and the odour disgusting."

(*Chairman.*) It is a mystery to me. I cannot understand it.

(*Mr. Webster.*) I submit to your Lordship that the way to understand it, if I may respectfully say so, is this: Nobody pretends that this takes place in winter, or that it takes place upon one single hot day, but that the comparative freedom of the last four years has been due to the very low normal temperature of the atmosphere and to the very large amount of fresh water in the river in those four years. Now, I say, if there is a hot July and some continuous hot weeks in August there is a strong smell given off from the mud, which is the result of the washing backwards and forwards of putrescible solid matter. There might be some of it in solution, that I am not chemist enough to know. May I point this out to your Lordship: Assume in the year 1880 a small amount of fresh water coming down, effect of the tide greater relatively, washing up and sending out of sewage by the Board. I do not suggest that they are doing anything wrong. I take it that they are obliged to do it, but being obliged to send it out while the tide is flowing up, the result is that you have sewage carried up 5 or 6 miles, and that sewage will deposit. Nobody imagines that that sewage goes backwards and forwards like a cork, it mixes, the specific gravity of it is altered, part of it goes to the bottom and part of it floats. I suggest to your Lordship that what this gentleman has spoken to as being the fact is in accordance with the scientific probabilities of the case; that there is this sewage washed backwards and forwards for a short time depositing its solid particles.

Now there was another witness, also of undoubted position, and making independent entries in corroboration of his evidence. I have called attention to Mr. Lewis, Captain Marsden, and Captain Fitzgerald, quite independent gentlemen in respect of their evidence being independent. I now refer to Captain James. Captain James has been harbour-master for a great many years, he begins at question 5174, he is 69 years of age and he has been upon the river 67 years, so he must have begun at two years old, but we will take him to have been 20. Now in 1880 he makes his entries in the month of July, and he is told to do it in consequence of the foul condition of the river, by a man above suspicion, and I ask you to look at the entries, take the 29th.

(*Chairman.*) Where is he the Harbour Master.

(*Mr. Webster.*) From Greenwich to London Bridge, and Captain Fitzgerald goes down thence to Greenhithe. Now I refer to Questions 5754. 5755 and 5760. At No. 5754 he is asked, "What is your entry "on the 29th of July," and he gives it as "water in "the river very black and offensive to the smell." (*Q.*) What is your entry on the 30th of July. (*A.*) "Water in the river very black and offensive," and at Question 5760, he is asked "What is your entry "on the 31st of July," and his answer was "The "water very black and offensive in the creek, as well "as in the river," that is below Deptford Dockyard, and a quarter of a mile above Greenwich. Then in the year 1881.

(*Chairman.*) Will you refer to Question No. 5756. Mr. Bidder asked the question, "Can you fix the "place" to which the witness replied, "From Green-"wich to London Bridge."

(*Mr. Webster.*) I say again it is an independent way of stating it, and I say it is one of those things your Lordship has often commented upon as an indication that the men are telling the truth. Just see what we have got. Mr. Lewis says Cherry Gardens, Captain Marsden says Millwall, Captain Fitzgerald says above Greenwich, this gentleman says Deptford Creek, and then my learned friend, Mr. Bidder interjects a question and the witness says from "Greenwich to London Bridge."

(*Chairman.*) Then at Question 5759 the witness was asked, "You are not able to specify any particular reach or anything of that sort? (*A.*) The whole of the river from London Bridge to Greenwich."

(*Mr. Webster.*) The man may not have been a very careful observer. My learned friend Mr. Bidder finds fault with him at Question 5773, because he had not any originality about his entries, but he is not the less truthful because he entered his observations in a formal manner.

(*Chairman.*) I do not doubt that he is telling the truth, but I suggest that if he has smelt it at London Bridge, he has smelt it from some other cause than sewage.

(*Mr. Webster.*) I cannot accept that.

(*Chairman.*) Nor do I positively affirm it, because it is quite certain that some sewage is carried up at times to London Bridge, because sea water will get up to Chiswick, as it has been proved.

(*Mr. Webster.*) I should agree with my learned friend Mr. Bidder, that the smell will keep in a man's nose, that his nose will carry it further than it exists, but in this case the man's district is below London Bridge.

(*Chairman.*) You are rather saying that the man's evidence is inaccurate, are you not?

(*Mr. Webster.*) No, I do not say that it is inaccurate.

11 July 1883.

(*Chairman.*) You say he carries it too far.

(*Mr. Webster.*) I say respectfully, that that is not the proper criticism to apply to the evidence. His terminus may be one that your Lordship thinks improbable, but sewage may have gone up above Greenwich. All I submit is that those are facts which he has spoken to. At Question 5787, he has spoken of from Greenwich to Limehouse, and these entries are made from time to time. My Lord, there are four of these men. I am not pausing to comment upon what I may call the smaller fish, but your Lordship will not understand me as throwing overboard or rejecting them at all. This is the character of the evidence which ought not to be mistaken. You have the entries of Limehouse and Deptford, in the witness's diary, and they are entries made at the time, it may be that he enters it formally, but your Lordship will not think the man was not entering the truth, because he was in the employment of a competent man. That the sewage can be taken high up under certain unfavourable conditions, of very little fresh water and the tide running up a very long way, the wind helping it up, and the sewers being obliged to run at a time when those who manage them, do not wish them to run, I think there can be no doubt is possible.

Now, I will refer you to Mr. Collingridge's evidence; he is the Medical Officer to the Port of London, and I would refer you first to his answer to Question 5860. "One of the witnesses told the Commission to day "that occasionally you find the water pretty clear on "the surface, but underneath of a much worse cha- "racter; as far as your experience is concerned, is "that true. (*A.*) Yes, certainly." And again, he is asked, "You have spoken of its being increased by the "stirring up of the paddles and also of the patches; "is it your view that those patches come from below "and spread over the surface," to which he replied: "I believe that the patches are caused by the in- "fluence of the tide, or some other influence bringing "up the sewage mud from the bottom of the water. "(*Q.*) How would you describe the patches. (*A.*) I "should describe them as very slightly diluted sewage. "(*Q.*) How do you judge of that? (*A.*) I have "taken specimens of these black patches and taken "them to my office in bottles and examined them. "They are very thick indeed, there is a very large "amount of suspended matter, and the smell from it "is horrible. A large quantity of the suspended matter "is pure sewage, fœcal matter. These specimens have "not been chemically examined. (*Q.*) But you have "no doubt of the correctness of your opinion that it "is sewage matter. (*A.*) I have no doubt whatever. "(*Q.*) Have you watched the stream as it flows out "from the outfalls? (*A.*) Frequently. (*Q.*) Can "that be traced for a considerable distance on the "river? (*A.*) At times. It depends very much "upon the state of the weather and upon the direction "of the wind." Then he describes the two streams and says that sometimes, "In the stream you have "these small pieces of fœcal matter which are small "as a rule, but sometimes you come upon very large "masses; you get matches, paper, and vegetable "matter, and a large quantity of corks at times." Now, my lord, it is beyond all suggestion that Mr. Collingridge should have overdrawn that picture. What I desire to impress upon your minds is, that this is a state of things, the possibility of which the board will not recognise. The board indicate by their chemical evidence that the thing cannot exist now, and they say that the action of the tide is as much as is wanted to deodorize the sewage, and that there is no necessity for anything more. I submit that the parties are not at one upon the question of fact, and that, if they were at one upon the question of fact, there would not be that divergence upon the question of chemistry, or upon the microscope. Now my point is, that this evidence comes from various independent men who have made their independent notes, and I ask you, can you not believe that, allowing for any exaggeration which you think ought to be allowed for, this does represent a very serious state of things, and a state of things which, if it can be avoided, the city of London ought to avoid?

(*Chairman.*) At Question 5,871 the witness is asked, "Can you tell the Committee how far that "stream which you say is distinguishable from the "water of the river can be traced?" and his answer was, "I have traced it downwards well into Erith "Bight" which is about three miles. I infer from that that the two streams have got by that time quite mixed, so that the one is quite indistinguishable from the other.

(*Sir John Coode.*) Each must have crossed the other by that time.

(*Mr. Webster.*) By that time you have got the two.

(*Chairman.*) There would not be any smell, there I suppose.

(*Mr. Webster.*) I do not know, that is a question of degree. I do not know whether anybody could answer that question.

(*Chairman.*) But it is of some consequence you know, because if this smell only lasted over a short space that is one thing; but if it lasted for ever, that is another.

(*Mr. Webster.*) If I was standing only upon the fishing evidence, though I submit that that is important itself, that the fish die and that the eels turn up when they get into this foul water, that the anchors are covered with a dirty and horrible black stinking incrustation of mud, that the clothes getting into the water are fouled, and that the cables and decks of vessels get dirtied, if that were the only evidence, I should ask you to hesitate seriously before you dismiss the thing as unimportant, but when I am able to point out not that one man has made a mistake, but that from independent sources the same evidence is given over the same period of time, it points to a very far larger existence of smell than a merely temporary one.

(*Chairman.*) Do you think that any ship coming up the river would pay 1*l.* to get rid of the stink.

(*Mr. Webster.*) I certainly think so, the owners of the ships would, I should say.

(*Chairman.*) 2*l.* would you say.

(*Mr. Webster.*) I am not entitled to advise your lordship as to that.

(*Chairman.*) It does not last all day.

*Mr. Webster.*) I do not admit that. I know your lordship does not put it to me as expressing a judgment upon it.

(*Chairman.*) I am merely putting it interrogatively, but I must not put the words into your mouth.

(*Mr. Webster.*) I submit that, under unfavourable circumstances it lasts very much longer than the sewer is running.

(*Chairman.*) Because there is a reservoir of deposit in the mud below.

(*Mr. Webster.*) And that, allowing for the emanation of gases, the causing of local pollution is not measured by the running in of the sewage water until it is oxidised, but that it goes very much further. Now, my Lord, I ask your Lordship to remember this, that there is a distinct admission by my learned friend Mr. Bidder, and there is the positive evidence of fisherman after fisherman, that the fish are driven below Gravesend.

(*Chairman.*) And they not only admit it, but they rely on it.

(*Mr. Webster.*) I do not regard it as an unimportant matter that the fish in the river should be utterly destroyed. I contend that it is an important matter.

(*Chairman.*) And so Mr. Bidder admitted at the outset.

(*Mr. Webster.*) No, not at the outset.

(*Chairman.*) At all events, very shortly afterwards, but he did admit that there is no fishing above Gravesend now.

(*Mr. Webster.*) He did not admit it before question 1906, when a great many fishermen had been exa-

mined. Now your Lordship is, I know, putting before me very kindly everything which is worthy of consideration. I do not admit that it is true that they have killed the fish to purify the sewage; that it is a necessary consequence, consequent upon the oxygenation going on. I did, in the earlier part of my evidence, dispute the statement that the mere oxygenating, for the purpose of getting rid of the nuisance, kills the fish. I say that it is not the oxygenation which gets rid of the fish, but that it is the polluting matter which turns them up; and I ask you not to dismiss this fish question as not being of importance in itself. I do not know whether they pretended that the other fish come above Gravesend.

(*Chairman.*) It is a mischief, and is conceded to be a mischief.

(*Professor Williamson.*) Is there any evidence which points to the fact that it is the fœtid matter in the water rather than the absence of oxygen which destroys the fish.

(*Mr. Webster.*) I do not know that there is; but I should beg to be allowed to remind the noble chairman of many fishery cases in which he has been judge in the Court of Appeal in which there has been actual polluting matter given as the cause of the death of the fish, and not the oxygenation, not that it makes much difference; but that it is an unavoidable necessity, in order to have the sewage purified, I respectfully question. Now at question 10,676, Dr. Tidy was asked by Dr. de Chaumont, "It was suggested to you in your examination that the "deficiency of oxygen in the water was one of the "causes of the death of the fish, but you did not, in "your answer, mean to imply that the fish might "not also have been poisoned directly by the water," and his answer was, "Certainly not. I do not know "as a fact to what extent the oxygen must be "deficient to prevent fish life, but I am equally "certain, first, that there may be varieties of organic "matter which may be themselves poisonous, and "secondly, I am equally certain that the formation "of sulphuretted hydrogen in the water, owing to "the action of the carbonic acid on the reduced "sulphates, would undoubtedly be poisonous to "animal life. As a fact, a very minute quantity of "sulphuretted hydrogen put into the water of an "aquarium will kill all the fish." That to a certain extent meets the point to which my attention was called, and I do not remember that there was anything else.

Would your Lordship now let me call attention to the evidence of a very different class of witnesses, and that is Captain Morrel, of the "Cornwall" and Captain Gillett of the "Warspite," which was evidence given early in the case, and this again is evidence upon a matter which I submit admits of no question. This is not a question of smells from factories. The "Cornwall" is moored at Purfleet. Your Lordship will find that having used the water for washing the decks, they discontinued it because of the stinking nature of the water that was used. Now, I do not think anybody has suggested that the smells of the factories would have got into the water so as to impregnate the water and get the smell on to the deck in that way. Your Lordship will find it at question 663, where Captain Morrel was asked, "Used you to "use it some years ago? (*A.*) Yes, for washing the "decks and for the boys bathing some times. "(*Q.*) Have you altered that practice for any reason? "(*A.*) I have discontinued it for several years. "(*Q.*) On what grounds? (*A.*) Because it used to "smell so bad that it was unhealthy. (*Q.*) What "kind of smell was it? (*A.*) A sickening smell, "arising from gases, it seemed to me. (*Q.*) Any"thing like a sewage smell? (*A.*) I can hardly tell "you that, for I have not been much in the vicinity "of sewage. (*Q.*) At any rate, you have given it "up for the purpose of washing the decks and for "bathing. (*A.*) We very seldom use it for washing "the decks; sometimes we might use it at the top "of high water for the purpose of washing the "upper deck, but never between decks, but just so "as to save fresh water." Then he is cross-examined by my learned friend Mr. Bidder, to show that at a particular period certain illnesses were not traced to the sewage; but I only remind your Lordship that in these very reports there was the fact that there was this smell of sewage, and that the water was so bad. Now Captain Gillett, of the "Warspite," which is stationed at Purfleet, below Woolwich, gave evidence, and I will refer you to his evidence; at question 803, he was asked, "Have you noticed as to whether the "water is in a pure or an impure state off your ship? "(*A.*) Just now it is very clear. (*Q.*) During the "last two or three years, can you tell us what has "been the condition of it? (*A.*) For a month in "the middle of the summer, generally in July, it has "been very bad." Now this is not a suggestion made to him. It is his own statement, "the water "becomes slate-coloured, and great masses of black "mud come up from the bottom and spread all over "the surface. (*Chairman.*) Has that been so this "summer? (*A.*) No, not this summer, yet. "(*Mr. Morice.*) But the last two or three years has "it? (*A.*) I did not notice it the first year I was "there, which was the summer of 1878, but in all "the succeeding summers it has been very bad "indeed, the smell is perfectly dreadful. (*Q.*) At "night time do you take any precaution with regard "to the ports? (*A.*) I am obliged to close all the "ports and keep the deck under the hammocks wet "with disinfectants." Now, whatever the cause may be, I submit to your Lordship that he cannot be mistaken in the fact that the smells come up over the river.

(*Chairman.*) Who is responsible for the situation of the "Warspite"?

(*Mr. Webster.*) I cannot say, but this I do point out, that the importance of it is that they have avoided the use of the water as far as they can for purposes where it might be injurious to health.

(*Chairman.*) Why on earth do not the authorities move the "Warspite" if the situation is objectionable?

(*Mr. Webster.*) I believe it is a matter which rests with the Thames Conservancy as to the point where they shall moor, so that they shall not interfere with the navigation of the river. I am informed that they shifted the "Worcester" from Erith to Greenhithe, now, would your Lordship look at question 828, where the witness was asked "And you find the sewage comes up to there" (that is Woolwich) to which the witness replies "Yes, it comes up to us, the whole "bed of the river, I believe, is covered with it, it "sinks, and when the temperature rises to a certain "point, it rises with it. It appears as if gases exploded "in the bed of the river, because it comes up and "spreads all over; it comes up in great masses of "black stuff, sometimes as big as this room." I have the impression that Professor Way gave a scientific account of something of the same kind.

Now, there are pilots, there are Custom House officers, there are policemen, there are inspectors of a superior description; there are inspectors of the Waterworks Company, men of not an ordinary description upon the river, there is the Chief Inspector of the Company, who was examined at question 3447, there are the dredger men,—in fact, I am not suggesting when I say that there are eight or ten different classes of people who speak to this thing, and who have observed it from different points of view.

(*Chairman.*) Do any of the Beckton gas people live on the other side of the river?

(*Mr. Michael.*) No, they live at Beckton.

(*Chairman.*) Have you any people who are in the habit of crossing the river?

(*Mr. Webster.*) I am told that they live at Woolwich, but I am not going to suggest—

(*Mr. Michael.*) All the Beckton gas people live at Beckton itself, as I understand.

(*Chairman.*) Is there any feeling about there?

11 July 1883.

(*Mr. Webster.*) It is at North Woolwich. Now, I do not suggest that in a normal year it will go as far up the river as in abnormal years, the year 1880 was an abnormal year, because it was very dry, and then, when an extraordinary thunder-storm came, these black masses sank to the bottom of the river. Now I refer again to the evidence of the witnesses, who have no reason for mis-representing this, and I do refer you to the answer of the sergeant of police at question 3214, which was, that in order to get rid of the dreadful smell that there was from the clothes, they were obliged to boil the clothes. That was the case of the "Princess Alice" in which some 200 odd bodies went into the river.

(*Chairman.*) Then you have the evidence of an intelligent medical man on the other side, who said that he saw no difference, but he had not the same reason for inspecting the clothes as the sergeant had.

(*Mr. Webster.*) No, he had not; he was called in just to pass the bodies.

(*Chairman.*) Besides that there is this remark, that would strike any man familiar with evidence, that one man saw it, and the other man did not, or was not asked about it.

(*Mr Webster.*) For all we know, the medical man's duty would not arise until the poor body was stripped by this man.

(*Chairman.*) No doubt both witnesses were telling the truth; the medical witness satisfied me that the people were drowned, but the other man says their clothes were offensive.

(*Mr. Webster.*) Now, I submit that that is quite abnormal, and cannot be referred to the ordinary condition of the bottom of the river. At this point I ask your Lordship to say that I have sufficiently called the attention of the Commission to the prominent leading and reliable evidence. I am not throwing overboard the other evidence at all, but it is not such evidence as I ought to occupy your Lordship's time by dealing with at length.

Now, I said that I should refer to the evidence produced by the Metropolitan Board of Works, and it is a very remarkable thing. I am not dealing with the chemical part of the evidence; but does your Lordship believe that it would not have been possible to have called persons who would have said, I have been going up and down the river for many years, and I have never seen anything like these patches. I cannot help saying that it is a fair observation, that if they could have got the evidence, they would have got it; it is an absence of evidence from people who live upon the river, which is noticeable. We have had people who have gone down for the purpose of this inquiry in years which, on all hands, are admitted to have been better years for their purpose; but it is a fact that there are only two witnesses who speak to anything connected with the water. We have had the medical men from the districts which are inhabited by what my learned friend Mr. Bazalgette has called the "riverine population," and they say that they do not think their health is affected, but they say, many of them, that they have smelt bad smells upon the river, and wondered that their health was not affected; but there are only two independent witnesses, Sir Frederick Abel and Captain Miller.

(*Chairman.*) I think Sir Frederick Abel gave evidence under a request from me.

(*Mr. Webster.*) I ask your Lordship not to take much account of Captain Miller. I cannot help thinking that the members of the Commission will have some recollection of the manner in which Captain Miller of the "Castalia" gave his evidence. I think you were not quite satisfied with the manner in which he gave his evidence. I asked him why he did not bathe when he was at Galleons Reach, and he said, "Why did I not bathe this summer in Erith Reach," not a very polite answer, and he is a master mariner, and he said that he always bathed at the top of the tide, though, when he was in a boat, he would have had no difficulty in bathing at any part of the tide.

(*Chairman.*) How could he bathe when a strong tide was running?

(*Mr. Webster.*) When he had a boat with him the boat would drift with him.

(*Chairman.*) But how do you account for his coming here to tell an untruth?

(*Mr. Webster.*) I do not say he did come here to tell an untruth; he is the one man who has not smelt it, but indeed he did smell it.

(*Chairman.*) What do you say to the medical man at Grays, who was in charge of some soldiers there?

(*Mr. Webster.*) Now, does your Lordship know that Surgeon-Major Griffiths, to whom your Lordship is referring, lives some distance from the shore below Purfleet, below the "Cornwall" considerably, and more than that, he never went there till the Autumn of 1880?

(*Chairman.*) And that there had not been a bad year since?

(*Mr. Webster.*) Not so bad a year.

(*Mr. Norman Bazalgette.*) You recollect that his garden ran down to the river.

(*Mr. Webster.*) Will you remember that he was below Purfleet?

(*Chairman.*) What I am suggesting to Mr. Webster is the case of a man who had been long upon the river.

(*Mr. Webster.*) My learned friend shall even have a reply upon me, endeavouring, if he possibly can, to point out any evidence of fact in contradiction to what I have suggested, though it is entirely unusual. I say again that they have called medical men who have been about their business, and who have come and said, no doubt the truth, when they said that they could not detect any diminution of health. No doubt their witness spoke of the health not being worse on board the "Caledonia" Hospital ship in 1859 and 1860, that being a very bad period, but I am correct in saying that Captain Miller is the only witness they have called from off the water. Now, your Lordship will observe, that Captain Miller was asked at Question 14,738, "What have you been doing there?" to which he replied, "I have been amusing myself "partly. (*Q.*) The "Castalia," being laid up, do "you remain there all day? (*A.*) Not all day. I go "on shore occasionally, amusing myself; shooting "sometimes. (*Q.*) I want to know this, have you "bathed in Galleon's Reach? (*A.*) Yes, I have, "once or twice. (*Q.*) You were there for three or "four years, why did you not bathe there more often? "(*A.*) I beg your pardon, if you will look at the "dates, seeing that I was there from 1877 to 1878, "you will find I was not there for three or four "years. (*Q.*) Did you bathe there? (*A.*) It did "not suit me to bathe there perhaps. (*Q.*) But why "did you not bathe in Galleon's Reach? (*A.*) Why "did I not bathe this summer in Erith Reach?" Then your Lordship put it to the witness. "Is it the "fact that you did not bathe there because the water "was not tempting, do you remember," and his answer was: "Not at all—by no means; if I thought I wanted "to have a swim, I should have gone in"; and then I asked him, "Do you suggest that the water in Galleon's "Reach was inviting to bathe in? (*A.*) Yes, it was. "(*Q.*) Was it just as inviting as in Erith Reach upon "the top of the tide? (*A.*) No, scarcely. (*Q.*) Why not? "(*A.*) Because there is not such a head of water "comes up there upon the top of the tide. (*Q.*) "Then the water is better in Erith Reach? (*A.*) "Yes; if you go round the river you will understand "that. (*Q.*) Erith Reach is three or four miles "further down then Galleon's Reach, is it not? (*A.*) "Yes, it is. (*Q.*) Now, you say you remember "the hot weather of 1881; how much of it was "there? (*A.*) I cannot say. (*Q.*) Was there a "week? (*A.*) I think there was more than a week. "(*Q.*) About what month was it? (*A.*) It was June "and July, I think. (*Q.*) The river began to smell "faintly, as you have said? (*A.*) Yes, it did. (*Q.*) "About how long after the hot weather began did

" the river begin to smell faintly? (*A.*) It was " smelling when the hot weather was on. (*Q.*) " What was it smelling of? (*A.*) That I cannot " say. (*Q.*) Can you describe the smell? (*A.*) " There are so many smells, I cannot pick them " out." I am justified in saying that this man (he is only one, and, therefore, the observation cannot be made against me that I am dealing with a number) may be unable to smell it; but, I have heard your Lordship say, that the evidence of a man who has smelt a smell is worth the evidence of half a dozen who say they have not. Now, I will call your attention to Question 14,763, where I asked the witness: " What I want to put to you is this—you do bathe " when you have the fullest amonnt of water up? " (*A.*) Yes. (*Q.*) Did you not know that the sewage " was let out upon the beginning of the ebb? (*A.*) " I did not know whether the sewage was let out " upon the beginning of the ebb or not." I think at the time your Lordship took the same view that I did, for you suggested to me whether I could not trust the Commission to draw their own conclusions as to this.

(*Chairman.*) I said, " The witness says, that shortly " after that he smells a strong smell, and we know " that is about the time the sewage is let out," and then I said, " Cannot you trust to us to know that " that is the time when the sewage is poured out?"

(*Mr. Webster.*) Then, my learned friend, Mr. Michael, is anxious that I should read the evidence of Mr. Griffiths. I may say, that he went to Purfleet, in November 1880; he knows nothing about the bad years before that, and he did for a long time smell a smell which he did attribute to the river, but now he does not, and he says, that the river was discoloured at the time; but now he has come to the conclusion that the smell was not attributable to the river. He is the one resident called by the other side.

Now I have finished the remarks which I have felt necessary to address to you. May I conclude by saying this. I repeat, as I said upon the very first day I came here, I am not here attacking the Metropolitan Board of Works in any way.

(*Chairman.*) Certainly not, they have succeeded to this business; there is probably not a member of it now who was in existence as a member at the first.

(*Mr. Webster.*) What the City have to do is to act as guardians of the health of the population of the City of London. They have had brought before them that this nuisance exists, as they are told, and exists to a serious extent, and they have to consider and see if this nuisance exists by solid matter in suspension being sent into the river, whether that is a proper thing to be allowed to continue. If the Commission think that there is nothing to complain of, no nuisance, then I am sure the City will be very glad that the river should have the certificate of character that your Lordship and the Commission can give it. If your Lordship and the Commission do think that that evidence which has been called by my learned friend, Mr Morice, and myself, and that evidence could have been strengthened by many more, (though I certainly do not see where the Metropolitan Board of Works could even have strengthened theirs) I ask you to report that though not perhaps now dangerous to health, it may possibly in the future, in the very hot weather, cause a serious outbreak. May I be allowed before I sit down to thank the Commission for the indulgence they have shown me in connexion with this inquiry.

(*Chairman.*) What I understand you to say is this, that the river and the mud are rendered stinking and offensive from somewhere about Deptford down to Purfleet.

(*Mr. Webster*) I think Deptford is too high as a matter of average. If your Lordship would ask me I would say, in exceptional years, as high as Deptford.

(*Chairman.*) In exceptional years as high or higher than Deptford and possibly as low as Purfleet.

(*Mr. Webster.*) Yes.

(*Chairman.*) Not during the whole course perhaps of the 24 hours, though there is no part of the 24 hours which is entirely free from it, because the gas might arise from the mud being stirred up, or from the mud flats and other things; and that this offensive smell does not arise at times, that is to say, if there is plenty of rain and fresh water it does not arise. That it is not specifically injurious to health but that it is disgusting to persons living and working upon it. That it interferes with the fishing and, I may say, even the navigation of the river.

(*Mr. Webster.*) And the enjoyment of the river.

(*Chairman.*) And that the fish are poisoned not only within the space I have mentioned but down as far as Gravesend, that is what you say that you have made out.

(*Mr. Webster.*) Yes, that is what we say that we have made out.

(*Mr. Beaumont Morice.*) My Lord, it would not have been necessary for me to say much to the Commission after the exhaustive remarks of my learned friend Mr. Webster, were it not that my learned friend Mr. Bidder, in the remarks which he has made and the evidence he has adduced, has endeavoured to show that there has been a cause of pollution by the district of Erith and that locality, especially. Now your Lordship will doubtless remember that I represent here specially what are termed Memorialists; and my Lord I have (and I believe Dr. Pole has the original here which was sent to him from the Home Office) a memorial emanating from 14,000 persons connected with the river, praying the First Lord of the Treasury to appoint a Commission in order that this matter might be investigated. Now, my Lord, there is in the schedule to that memorial a list of the members forming the general committee, and your Lordship has asked just now whether the shipowners would give anything in order to do away with the smell coming from the river. My Lord I find that amongst this general committee there are steamship companies, including the P. and O., and the British India, and all the leading steamship companies in the port of London, who have signed this memorial, together with a large number of merchants and other persons of position in the neighbourhood who have desired that something should be done in order to put an end to this complaint of the pollution of the river; so that the general character of the persons who have signed this memorial would go to show that the nuisance, as I have had occasion to mention before, is of a widespread character; and that there are therefore a large number of persons of all classes who are desirous that something should be done. Now when my learned friend Mr. Bidder in his remarks the other day referred to the evidence that had been brought forward on behalf of the Memorialists, he referred to them as an uneducated lot of persons who were giving vent to their feelings. Now perhaps that might be so if we were only dealing with the fishermen, but my learned friend, Mr. Webster, has referred to those, and I would therefore only say, seeing that there were such a number of them, not only those who were called, but of those who were in reserve, and who would have substantiated what those who were called said, that if some of them were mistaken all of them could not be.

Now, so far our evidence from being confined to fishermen, I called, as your Lordship will recollect Mr. Beadle, a resident of Erith, who has been there 35 years and employs a large number of workmen and is therefore able to speak to what has been complained of. In addition to him I called Captain Morrel, Captain Gillett, the Local Board Inspector of Erith, Mr. Carttar, the coroner, the Master of the East and West India Docks, the Inspector of the Watermen's Company, the pilots, and different sorts of people, to show the Commission that the complaint was by no means confined to one class of persons, but was generally shared in by all classes, in fact all persons having business upon the river at all are at one in this matter.

Now it would not have been right upon my part to bring before the Commission persons who, like

11 July 1883.

steamship owners, have not any direct knowledge of what they would have come to prove, but I am obliged to go to persons who have actual contact with the nuisance, with the smell, and with the mud and with the sewage deposit which exists upon the river, and for that reason I did bring undoubtedly a great number of persons who may be in the lower ranks of life, but who may be taken to be pre-eminently qualified to give evidence of value upon this question.

(*Chairman.*) Did you bring any captain of a steamboat forward?

(*Mr. Beaumont Morice.*) Yes, I did, my Lord.

(*Chairman.*) And you brought some pilots?

(*Mr. Beaumont Morice.*) Yes, I brought some pilots, and a captain of a tug also, the tug "Wildfire."

Now I would just, if your Lordship will allow me, instance the points which I think I have put before the Commission, and which I think the witnesses have proved. Now the first point has been that there has been a great alteration in the character of the water of the river, that is to say, this alteration has been fixed at a time within a short period after the opening of the outfalls, and that whereas before that there was a good deal of unpleasantness up here at Westminster and it was clear down below, the position has been altered.

(*Chairman.*) I do not think they deny that upon the other side, because confessedly the fish are killed by some condition of the water which must have been different from what it was when the fish could live there.

(*Mr. Michael.*) And whether it is brought about primarily or secondly is not of much importance.

(*Chairman.*) It is not of much importance.

(*Mr. Beaumont Morice.*) That must have been within four or five years after the opening of the outfalls, and within the last nine or ten years that condition of things has become very much worse. Now Mr. Beadle fixed that very clearly to the Commission; he said, he thought the river was not charged with sewage very much at first, but was getting worse every year. That was the evidence of other witnesses, Mr. Sandford and Captain Walter of the "Arethusa," the latter of whom said that he had been there eight years, and that the river was getting rapidly worse. So that not only have you one person stationed at one part of the river——

(*Chairman.*) I do not see how that is a physical possibility, because if it were physically possible, one would think that the river in time would become all Cray water, for example: There is a river called the Cray, that falls into it, but it does not become more Cray water than it has been in the last thousand years, and if it does not, why should it become more sewage water.

(*Mr. Beaumont Morice.*) I quite follow your Lordship, but your Lordship will allow me to say, that the sewage is very greatly increasing, and in addition to that increase there is the admitted pouring in of the sewage before high water. So that you have these two states of things, you have the additional amount of sewage in itself, and you have the probability, and the very great possibility, of a large portion of that sewage remaining in the river; a portion of it going up and next day going down. So that when you come to the evidence of Captain Gillett, you will remember that he says, he saw the sewage up there; and your Lordship noticed that remark in his evidence, where he says he always did have the sewage; that it is always present; that would be so, if he, a short space above the outfall, does have the sewage coming up with the flood, and then going back with the ebb, and if he is obliged to close the ports, and so on, he would have the sewage constantly present with him. He was asked, whether the sewage did come up as far as his vessel? and he said, No doubt it does come up, we have the sewage constantly present with us. It is because of the increasing nature of the sewage volume which is constantly put in, and the deposit that is accruing, that this state of things is stated by the witnesses to be becoming worse and worse.

Now what is also stated by the other witnesses I have called is, that the state of things in the river with regard to the condition of the water has been becoming worse and worse in recent years; and although you may get a year which is better by reason of its being cooler, and there being more fresh water in the river; yet that the general state of things is, that the river is getting rapidly worse and worse.

Now with regard to the question of fish. I mention it only for this purpose, that when my learned friend, Mr Bidder, admitted that the fish were gone, he would not accept your Lordship's remark that the fish had been poisoned, but he says, I admit that the fish are not there but I do not admit that their absence is due to the sewage outfall; and when your Lordship finally asked him if he did not admit that they were poisoined, how did he account for their going away; he declined to make any further admission except that they found that the fish were not there, that in fact it was not thought advisable to bring them through the sewage zone. Now the fact remains that the fish were there before the sewage outfall was opened, and they remained there a year or two afterwards, and that they have been gradually driven down reach by reach until they have at last got to Gravesend and places below Gravesend, where alone they can be found. Upon the point of the fish I venture to say that the evidence is conclusive.

(*Chairman.*) There is no doubt about it that they are not in the river. I think none of us have any doubt that directly or indirectly the sewage has caused the fish not to be above Gravesend. I think that is admitted.

(*Mr. Michael.*) The only difference is the word that my learned friend has put in, namely, the "outfalls."

(*Mr. Beaumont Morice.*) The next matter which my learned friend, Mr. Bidder, said had been specially put forward by the Erith witnesses was the case of the mud deposit. Now at the outset my learned friend tried to show that that was the identical matter which had been settled in the Mud Enquiry, now that is not so. Your Lordship remembers, and I think your Lordship mentioned it, upon one or two occasions, that that was a question of the navigation of the river. What the banks were composed of was very indirectly in question at all, and for my purpose it is of very small consequence what has caused these banks to accumulate in the first instance; the question is, what is their composition now; but if I can show as I think my witnesses do show, that they are composed of sewage.

(*Chairman.*) How do your witnesses prove that?

(*Mr. Beaumont Morice.*) First of all Mr. Beadle proves that it is black stinking mud different from what was there formerly. He stated that he had had a steamer sunk there, and not only had he a very great difficulty in getting his men to work in consequence of the filth but that when she came up she was covered with filth of a sewage nature. Then you were told about the causeway and how it had to be lengthened, how it was covered with slime and black mud to a very great depth on both sides of the causeway.

(*Chairman.*) Has the mud been analysed satisfactorily on either side?

(*Mr. Michael.*) Yes, microscopically and chemically.

(*Chairman.*) I know it has microscopically, but has it chemically?

(*Mr. Michael.*) Yes, it has.

(*Mr. Beaumont Morice.*) Now there was a pilot named Bushby who stated that he sometimes would sleep on shore and when he went on board in the morning he said the place was ankle deep in slush; and then he went on to say that Erith was "the essence of the jelly-bag."

(*Mr. Michael.*) Let the Commission read the question and answer No. 403 "(*Q*). Have you noticed "whether in hot weather there is any sewage depo- "sited upon the bank? (*A.*) I have not noticed

" anything that I could call sewage, it seems to be " washed up into a thick state and diluted very much " with water."

(*Chairman.*) Whose evidence is that?

(*Mr. Michael.*) This is the evidence of Mr. Beadle.

(*Mr. Beaumont Morice.*) Now, my Lord, I mentioned Captain Gillett of the "Warspite" upon the subject of the sewage deposit for this reason, that he mentioned the subject that your Lordship mentioned, namely, the sewage that he found upon his mooring-chains. He had occasion to have his moorings moved, and his attention was drawn by Mr. Wood to the chain, and he went and saw for himself that it was sewage upon it, and I believe that sewage was analysed afterwards.

Now, upon the question of deposit, you will remember the witness Michael Hind, who gave his evidence with regard to Erith Causeway in particular. Now, Michael Hind is a man who is a member of the Local Board, and has lived there nearly 50 years, and had been boating there from his boyhood, and lived upon the river. He stated that he had been upon the causeway that morning at 8 o'clock, and that it was covered with black stinking mud, and he was asked by Professor Williamson as to whether the causeway had caused the accumulation of mud; that is to say, whether the causeway was built, so that it would form a kind of breakwater, so that the mud would accumulate on one side rather than on the other; and he said, in answer to question 1208, that there was nothing of the kind, that the mud was not in any way due to the causeway, that it was on both sides; that he had tried the depth of it, and found it to be from 9 to 10 feet deep. He also told you that he was an undertaker, and that he had to do with the bodies from the "Princess Alice" and also with the bodies of the cadets of the "Worcester" some years ago before the outfall was opened when the "Worcester" was moored off Erith, and that he found the bodies from the "Princess Alice" were filthy in the last degree, while nothing more than ordinary river mud was found upon the bodies of those who were drowned from the "Worcester." Then the witness Savery, who was a custom house officer at Erith, followed in the same way; he put his scull down to see how deep it was, and he said, " the scull was only twelve feet, and we pushed it " down some five or six feet, and I have no doubt, " that had it been longer we could have gone deeper, " but, so far as we could ascertain, it seemed all to " be of the same character, black sewage smelling " material, not such as you would get from the banks " of the Thames."

(*Chairman.*) I do not know about that, because no doubt, if it had been the natural bank, it would not have been easy to get your scull down five feet deep, but supposing it had been mud washed up from the river?

(*Mr. Beaumont Morice.*) He might have been able to put his scull down, but he would not have had the black sewage smelling material. Then there are several witnesses who speak of it in very concise language. The witness Hathaway said it was black stinking stuff, he could not call it mud. The witness said, when he got the anchor up, he had to employ a man with a brush for him to sweep the chain before it came on board, because of this stuff staining the deck.

Now there is one witness whom my learned friend, Mr. Bidder, did not refer to at all; in fact, several of those witnesses he did not make any mention of. You will remember the witness Fuller, a member of the firm of G. and F. Fuller, who dredge for gravel down the river. And what did he say? He commenced in the upper part of the river, and he told the Commission how he had, or his men had, to go down the river, reach after reach; that they would stay six months in a reach, and then they would go further down, and at last they had to go to Coalhouse Point beyond Gravesend to get gravel, and only that morning he had the report that the Gravesend gravel was impregnated with sewage, and he described to the Commission how this sewage exists; that it is upon the top of the gravel; that it is from 18 inches to 2 feet thick in many parts, and that his customers would not have it in consequence of its being so impure. Then one of the members of the Commission asked him "If you go to salt water would there not " be a considerable deal of salt in the gravel that you " get," and he said, "Yes; but they prefer the salt " rather than the sewage," and he told you the different colours; that the mud was whitish at the top, whereas the sewage was of a reddish brown; and he appears to have had a good deal of experience in this matter. Then I called several of the captains of the dredgers who were actually engaged in the work, and who corroborated from their actual experience what Mr. Fuller said from his knowledge as an employer.

Now, as connected with that, there has been proved to be a very distinct smell from the mud as well as from the water. I specially ask the attention of the Commission to that, because my learned friend, Mr. Bidder, in cross-examining the witnesses as to the smell, seemed to be rather amused at the distinct way in which they described the smell. Mr. Beadle, I believe, began by stating, that it was like a closet smell. He states, that the water gives off gas; that it turns black, and that it gives off gas from bubbles, which have a disagreeable smell. Then in answer to Sir John Coode at Question 259, he says, you can see these bubbles break upon the surface of the water, and in describing the smell, he says, "It is like a " badly ventilated water-closet if you go into it in " the morning." Now Bushby, the pilot, was asked about the smell, and he says, I can only describe the river as being the largest cesspool in the world; and he told the Commission the best way to smell it. No doubt the Commission are desirous to see the Thames at the time when it is best to smell it. He said, if you leave Gravesend at five o'clock in the morning in the month of July or August, or if it is a dry season, in the beginning of September, and the water comes up and it is quite still, especially if the morning is quiet and still, you get the smell to perfection. He stated also, that in going down with vessels, he has known the mate to knock off the men from washing the decks until they had got past the sewage district, and then to recommence; because in addition to its being filthy water, it was water which stained the decks of the vessels.

Now Captain Morrel of the "Cornwall" described that as a sickening smell, and so did Captain Walter of the Royal Navy and of the "Arethusa." He described it as a sickening smell; and Captain Gillett states, that the smell is perfectly dreadful. Now if only two persons had mentioned about the cesspool smell, it might have been a matter of amusement more than anything else; but nearly all those witnesses agree in the character of the smell. Mr. Egerton, the Surveyor to the Erith Local Board, describes it as like a cesspool emptied two or three days: "It would " then smell somewhat similar to what it would if it " had not been disinfected and cleaned." He states, that his house is above the river, and that in coming down from his house of a morning, he gets into this sewage smell, and it is very difficult to get out of it; that he can get out of other smells, but not out of that smell, and if the morning is of a foggy character, he is unable to get rid of it altogether.

Now the next witness I called upon this point was Michael Hind; he went into exceeding detail about it, for he told you exactly how many days old that cesspool smell appeared to be, and he agreed as to the smell exactly, so much so that my learned friend Mr. Bidder asked him whether he had been comparing notes with the previous witness, and he said "No, if " you went to smell it you would soon see whether it " was a cesspool smell," and he said he smelt it when the wind was north-east or east. Now that is important as regards the objection which has been made

11 July 1883.

that the smell came from factories. Now a north-east wind or an east wind could not bring any smell from the factories; and the evidence of Hind is that the time when the smell is strongest at Erith is when the wind is north-east or east.

(*Chairman.*) That will be when the wind is blowing from Erith towards the sewage.

(*Mr. Beaumont Morice.*) No, from Purfleet, towards Erith.

(*Chairman.*) I remember it, but I cannot make it out, an easterly wind would come to Erith before it came to the outfall.

(*Mr. Beaumont Morice.*) Yes, certainly.

(*Chairman.*) And a north-easterly wind would blow at right angles to a line drawn from one to the other.

(*Mr. Beaumont Morice.*) Yes, from Purfleet.

(*Sir John Coode.*) You mean it would not have come from the factories.

(*Mr. Beaumont Morice.*) Yes.

(*Chairman.*) Then it must have come from the sewage after it had got below Erith.

(*Mr. Beaumont Morice.*) Yes, exactly.

(*Mr. Michael.*) No, below Purfleet.

(*Mr. Beaumont Morice.*) All the way up the Reach from Purfleet to Erith. Now, my Lord, other witnesses agreed with respect to the cesspool smell.

(*Chairman.*) Who was this man?

(*Mr. Beaumont Morice.*) He was the auctioneer.

(*Chairman.*) Probably he did not know the north from the south. I will be bound if you were to ask half a dozen people in this room you would find they did not know which way this room looked.

(*Mr. Beaumont Morice.*) However, I do not think they would make any mistake about the easterly wind. Now I will take Captain Hussey, the principal dock-master of the East and West India docks, he said his house is within 20 feet of the river, and that the stench is something awful in the summer time. Now my learned friend Mr. Bidder talks about "uneducated "persons" and "atrocious exaggeration," as he is pleased to term it, but here is a gentlemen who certainly knows something about the river and nautical matters.

(*Chairman.*) He is in a favourable situation for the West Ham sewage.

(*Mr. Beaumont Morice.*) That may be, but there is not much sewage from East Ham which I think your Lordship means.

(*Chairman.*) No, I mean the West Ham sewage which comes down the Lee.

(*Mr. Beaumont Morice.*) Now my learned friends say, This is due to your factories, and they parade out all the factories on both sides of the river. My learned friend, Mr. Bidder, actually had the boldness to tell your Lordship the other day that the witnesses who were here to speak about the smells were unable to discriminate between the smells of the river and the smells of the factories. Now if there is one thing more than another my witnesses proved, it is that they can discriminate between the smells from the factories and the smells from the river. They say we can tell when the smells from the factories are coming. We have what Sir Frederick Abel would describe as "an "educated nose" and can tell the factory smell from the sewage smell, and the sewage smell is much worse than all the others. Now Mr. Beadle began when he was cross-examined by saying, "This smell was quite "unmistakeable," and so did all the other witnesses who followed. Now I can go beyond my own witnesses, because upon this point my learned friends have very kindly furnished me with witnesses to support what mine have said. Mr. Chatterton was called, and I asked him in cross-examination whether he could tell the factory smells from the sewage smells, and he said, "I can tell the different factory smells by "putting them in groups" and in another answer at No. 13,369 he said, "I think I could tell the smell of "the sewage below the outfull from the smell of the "factories; Oh, yes, certainly I could. Sometimes "they are a little alike, but, with practice, your nose "can detect the difference." Now my contention here is, that the witnesses I called, and the inhabitants of Erith generally, have unfortunately had considerable practice with their noses in telling the difference between these smells, and therefore it is upon the strength of that, having lived in the locality for so many years, that they come here to tell your lordship what even Mr. Chatterton, with his little experience of Erith could say, namely, that they could detect the difference between the smell of the factories and the smell of the sewage.

Now what does Mr. Easton say—he comes here and complains of the drainage of Erith, and, complaining of the drainage of Erith, I asked him whether he could smell the sewage as distinct from the factories, and he stated that he could smell it. I asked him if he could distinguish between the two, and his answer was,—I do not think there is any doubt about it; and Sir John Coode will perhaps remember that he asked him specially, because he does not appear to have given a very clear answer as to whether he could distinguish the sewage as a nuisance at Erith, and his answer is, "When once "you have smelt the sewage smell and the factory "smell, there will be no doubt about it." That is exactly what I put before the Commission as what my witnesses have said; there can be no doubt about the matter to those who had had any experience at all.

But the further objection which the Metropolitan Board of Works raised to the evidence which I brought forward with regard to the factories was,—If this be so, if it is the sewage and not the factories, why have you always complained about the factories and not about the sewage? There does seem so apparent a reason why they did not do so that one hardly needs to put it forward in the ordinary way. Here is the Local Authority, having jurisdiction and power to abate the nuisance from factories within their limits, and they have taken remedies for the purpose; and you had it from the surveyor to the Local Board that, since they had used those powers the nuisance has been very much less, but they have no power over the Metropolitan Board of Works with regard to the Metropolitan outfalls, and, for that reason, it would have been useless to take any action where they could do nothing with any salutary effect.

Now my learned friends on the other side say,—Oh, we will show that the Erith sewage is the cause of all this smell. My Lord, they called, for that purpose, the surveyor. I recalled him in order that he might show to the Commission what was the exact state of the drainage of Erith, and he showed that out of 1,883 rateable houses in the parish of Erith, only 507 drained into the river. That may be the misfortune of Erith; it may be a reason why Erith should have a drainage scheme; but, for the purpose of this Commission, it is perfectly clear that they cannot cause any pollution to the river when only 507 houses drain into it. Mr. Egerton was asked what were the sewers, and he said they were 7, 9, and 6 inch pipes, and in addition to that there was a small pipe of 5 inches, beyond that there was no pipe which he, the recognised authority, knew of in the neighbourhood of Erith. Now one of the honorable Commissioners asked what became of the slops that those houses made, and he said the slops of the 507 houses go into the sewers, but not any of the others. All the others have cesspools, and therefore a large part of the parish of Erith, which he told you is a very straggling place, is drained into the cesspools, and only 507 houses are drained into the river itself. Now Mr. Chatterton, when I asked him if he was prepared to tell the Commission that those 507 houses, draining into the river, amounted to a nuisance said "Yes, "it would be a nuisance if put upon the table," he seemed at once to realize the absurdity of this assertion by at once adding "Or if you put it into this room," but when you come to contrast that with the pollution of the river by 4,000,000 people, it does seem somewhat absurd to say that the drainage of 507 houses

can cause the nuisance of which the Erith people complain. Now, at this point, they gave me Mr. Easton as a witness again. He was the engineer, and he said that the point he had to complain of with regard to Erith, was that it was not properly drained. I can quite believe, from an engineer's point of view, that a place that has 1,300 cesspools is not properly drained; but I claim him as a witness in my favour, because he went on to say that he did not know about the nuisance at Erith, and then he was asked by Sir John Coode, at Question 15,352, "Then your view is "that there is no nuisance," to which he replied, "I do not think there is a nuisance in the river "arising from sewage at all," and again, he is asked, by Sir John Coode, whether there is a nuisance in the Metropolitan or the Erith sewage, and he says "I do not think you could smell Erith sewage *qua* "sewage."

(*Mr. Michael.*) He could not smell Erith sewage in the river.

(*Mr. Beaumont Morice.*) He could not smell the Erith sewage, so that Mr. Easton's complaint of Erith as he says, is that it is not properly drained; that may be so, but how far it cause the pollution in the river is proved by Mr. Easton himself, when he says he does not know what the nuisance is that is complained of in the locality; he is there speaking of the drainage system of the place.

Now, I only want to place one other point before the Commission. Erith is a place of something like 10,000 inhabitants, and, my Lord, it does seem exceedingly strange, when I have brought before the Commission a number of witnesses who have come from that locality, and from places close by, and who have agreed in their evidence not only about the deposit of sewage mud, but about the smells due to sewage, and who have been able to distinguish between the smell of the sewage and the factories, it does seem strange that my learned friends have not been able to bring forward a single person from that locality to controvert these statements.

(*Chairman.*) They called Mr. Easton.

(*Mr. Beaumont Morice.*) He only went there on a visit.

(*Mr. Norman Bazalgette.*) His works were there, and he was there constantly, visiting his works.

(*Mr. Beaumont Morice.*) But he has not been a partner in these works for some years.

(*Mr. Michael.*) He was the engineer employed by Erith to report.

(*Mr. Beaumont Morice.*) Now all that they have brought has been Mr. Chatterton, who has been there several times last year. Now I asked Mr. Chatterton, when he came to say that there was no complaint from Erith or Erith people, how often he had been down there, and your Lordship may remember I took him from 1872 to 1882, and he told me that he had been not very often, not much, not often. And therefore, except in the year 1882, when he was making certain enquiries and soundings for the purpose of this Commission, with that exception, they have brought forward no evidence to show what is the condition of this mud. Therefore, my Lord, I do say, that having put before you a number of witnesses, and having a great many more in reserve, of different classes, who, if the Commission would wish, I could tender before you, to support what has been said already, it does seem very strange that my learned friends have not been able to bring before you any local evidence upon this question, such as you can, in cases where exaggeration has taken place, easily bring up from a district, to say either that the statements are not true, or that they have been grossly exaggerated. Now, I think when my learned friend referred to the uneducated persons who have been before you here and stated that they had made atrocious exaggerations, it would have commended itself more to your Lordship and the other members of the Commission if he had brought forward evidence to controvert what they had said, bearing in mind that those persons have agreed in the main with the evidence which has been given by other witnesses before the Commission. I now wish to thank the Commission for their kindness to me during the inquiry. I do not know whether they have decided about hearing further evidence.

(*Chairman.*) We have not.

Adjourned *sine die*.

# APPENDICES.

## APPENDIX J.

Extracts from Correspondence received from the Home Office, July 1882.

Guildhall, E.C.,
Sir, 19th January 1882.

The question of the pollution of the River Thames by sewage from the outfalls at Crossness and other places has recently been the subject of serious consideration by the Port of London Sanitary Committee of the Corporation; and, guided by personal inspection and the results of a careful chemical analysis of the water of the river in the localities in question, they find that without doubt the state of the river at Crossness and Barking Creek (although in consequence of constant meteorological changes it must of necessity vary from time to time) is, from the great outpouring of sewage, always in a condition most unsanitary, exercising, in periods of drought and great heat, very prejudicial effects upon the public health; and bearing in mind the fact that the quantity of sewage has of late years enormously increased and is constantly increasing, the Committee feel that the time has arrived when some decisive action should be taken in the matter, and they therefore deem it expedient to take the step which, under the Metropolis Local Management Act, 1858, cap. 104, sec. 31, is open for adoption, and I am therefore instructed to urge upon you the extreme importance of immediate steps being taken towards remedying that which must be admitted to be a great and growing evil.

I have, &c.,
(Signed) John B. Monckton.

To the Right Hon.
Sir W. Vernon Harcourt, M.P.,
Secretary of State for the
Home Department.

---

Metropolis Local Management Act Amendment,
21 & 22 Vict. cap. 104.

S. 31. It shall be lawful for one of Her Majesty's Principal Secretaries of State, at his discretion, on representation or complaint made to him of any nuisance committed in execution of any works, or in deodorizing any sewage, or in disposing of any sewage or refuse from sewers, or in any other manner under this Act, to cause inquiry to be made into the matter represented or complained of to him, and to direct such prosecution or prosecutions, or to take such other proceedings, as he may think fit, in order to ensure the prevention or abatement of such nuisance as aforesaid.

---

14 Berkeley Square, W.,
21st January 1882.

Dear Sir William Harcourt,

The Woolwich Local Board of Health, who have passed a resolution of which I enclose a copy, wish me to ask you to be good enough to receive a deputation from them on the subject of the said resolution.

If convenient to you to do so, I should be glad to know what day in the early part of next month would best suit.

Yours faithfully,
(Signed) T. W. Boord.

The Right Hon.
Sir W. V. Harcourt, M.P.,
&c. &c.

---

Copy of Resolution passed by the Woolwich Local Board of Health.

That an application be made to the Secretary of State for the Home Department to receive a deputation from this Board upon the subject of the pollution of the Thames by the discharge of Metropolitan sewage into the same, and to seek the help of the Government that the present nuisance, caused by the discharge of the sewage, may be abolished as soon as possible, the same being considered detrimental to the health and comfort of the inhabitants of the town, the workmen in the Government establishments, and the troops in garrison.

Also to draw his attention to the proposed enlargement of the sewage works in this and the neighbouring parishes, which is not for the purpose of the utilization of the sewage, but for the continuance of the present wasteful and unsanitary system.

---

Guildhall, E.C.,
Sir, 7th February 1882.

I have had an opportunity to-day of laying your letter of the 4th instant (A. 12786) before the Port of London Sanitary Committee, by whom I am instructed to lose no time in sending you, for the information of the Home Secretary, the enclosed report,* which will, it is thought, afford the fullest information on the very important subject it deals with. If the Home Secretary thinks I can in any way usefully supplement this, I shall be glad to do so.

I have, &c.,
(Signed) John B. Monckton.

To Godfrey Lushington, Esq.
Home Office, Whitehall, S.W.

---

Local Government Board,
Whitehall, S.W.,
Sir, 9th February 1882.

I am directed by the President of the Local Government Board to state, for the information of Secretary Sir William Harcourt, that in September last the Board were furnished with a copy of a resolution passed by the Vestry of Plumstead with regard to the pollution of the River Thames by sewage from the works executed under the Metropolis Local Management Acts, and in which the Vestry expressed an earnest hope that the Board would concert measures to remedy the evil. A short time previously the Board's attention had been drawn to the alleged nuisance created by the works in question by an influential and representative deputation from the locality.

The Board have been in communication with the Conservators of the River and the Port Sanitary Authority of London on the subject, both of which authorities express their sense of a serious contamination of the river from the source referred to; and the Board learn from a letter addressed to them by the Port Sanitary Authority on the 19th ultimo that a

* Reports by the surveyor and analyst to the Woolwich Board of Health, 22nd October 1878.

APP. J.

representation has been made to the Secretary of State in the matter.

The President will be glad to be informed whether it is proposed to take any action in this matter under section 31 of the Metropolis Local Management Act, 1858.

I am, &c.,
(Signed) JOHN LAMBERT,
Secretary.

To the
Under Secretary of State,
Home Office,
Whitehall, S.W.

---

Army and Navy Club,
Pall Mall, S.W.,
15th February 1882.

SIR,

I AM gratified to observe from the reports in the newspapers of the statements you made to the deputation from Woolwich as to the pollution of the Thames, that it has not escaped your memory that you assisted as counsel my late relative Mr. Napier and myself in obtaining in 1865 an Act to authorise the carrying out of our scheme for freeing the Thames from the "sewage of the northern area of the Metropolis."

It will also probably be in your recollection that the scheme had been originally presented by us to the Metropolitan Board of Works in 1861, and that during that period of four years it was not only exhaustively inquired into by the Board, but also twice, namely in 1862 and 1864, by the House of Commons.

You will also doubtless recollect the severe fight we had in committee, and the influential opposition which the bill met with in some quarters, but that eventually, the scheme being thoroughly sound, the bill passed triumphantly through both Houses.

But the subsequent history of the scheme is probably quite unknown to you; and in the belief that the fact may be of interest and even of use to you at the present moment, I have the honor to inform you that, owing to the arrangements which I made after the passing of the Act in 1865, and which were embodied in a deed (under seal and therefore binding for 20 years), the whole of the money is, if the Metropolitan Board will only do their duty to their constituents and the public at large by enforcing the deed, *already provided* for diverting the northern and most offensive as well as vuluminous portion of the sewage for ever from the Thames without expense, and even with profit to the ratepayers.

Perhaps you will allow me to add that if at any time you desire my assistance in the matter, I myself and all my papers and information are, most unreservedly, at your absolute disposal.

I have, &c.,
(Signed) W. HOPE.

The Right Hon.
Sir W. Vernon Harcourt, M.P.,
Her Majesty's Principal
Secretary of State
for Home Affairs,
&c. &c.

---

Metropolitan Board of Works,
Spring Gardens, S.W.,
6th March 1882.

SIR,

REFERRING to the letter adressed by direction of the Secretary of State to this Board on the 10th instant (No. A. $\frac{12786}{3}$) with a copy of a communication from the town clerk of London as to nuisance alleged to be committed in the disposing of the sewage of the Metropolis at the outfalls at Crossness and Barking Creek, I am directed by the Works and General Purposes Committee, to whom the same has been referred, to acquaint you, for the information of the Secretary of State, that they have considered it desirable to remit the matter to a sub-commitee for inquiry, and that upon their report being presented a reply will be sent with as little delay as possible.

I am, &c.,
(Signed) J. E. WAKEFIELD,
Clerk of the Board.

The Under Secretary
of State for the
Home Department,
Home Office,
Whitehall, S.W.

---

Guildhall, E.C.,
29th March 1882.

SIR,

*Pollution of the River Thames by Sewage.*

REFERRING to your communication to me of the 10th ultimo (A. 12,786) in which you state that the representation of the Corporation made to you in my letter of the 19th January last, and also the report of the Port of London Sanitary Committee transmitted to you by me at your request on the 7th ultimo have been referred to the Metropolitan Board of Works for their observations thereon, I shall be glad to know, for the information of the Committee, who meet on Tuesday next, whether you will now take action in the matter as contemplated by the statute.

I may state that considerable anxiety prevails on the subject in the neighbouring parishes.

I am, &c.,
(Signed) JOHN B. MONCKTON.

To the Secretary of State,
for the Home Department,
Whitehall, S.W.

---

Metropolitan Board of Works,
Spring Gardens, S.W.,
4th April 1882.

SIR,

I HAVE to acknowledge the receipt of your letter of the 31st ultimo, forwarding a copy of a letter from the town clerk of London, asking whether the Secretary of State will take action upon the representation made to him by the Port of London Sanitary Committee, a copy of which you sent to the Board on the 10th February last.

The representation is to the effect that the discharge of sewage into the Thames from the Metropolitan outfalls is productive of injury to the public health, and the Secretary of State is asked to take the action prescribed by the 31st section of the Act of 1858, known as the Main Drainage Act, that is to say, to cause inquiry to be made, and to take such other proceedings as he may think fit.

The Board is not yet in a position to make a complete reply to the Secretary of State on the allegations put forward by the Port of London Sanitary Committee. It would wish to continue the investigations it is now making during the time when hot weather prevails, and when the state of the river is alleged to be at its worst. So far as the Board's recent examinations have gone, however, they point to the same result as has followed on all previous investigations, that is to say, that the statements with respect to the polluted condition of the river and the effect on the public health are, if not totally unfounded, greatly exaggerated.

That the water of the Thames is not so pure as could be wished may be admitted without hesitation, but there are other sources of pollution than the Metropolitan sewage outfalls, which would go far to account for the conditions which give rise to complaint.

The Board confidently expects that the further information to be obtained will but confirm the view which at present the Board has every reason to hold, that the sewage outfalls cannot be charged with such a pollution of the Thames as to cause serious nuisance or any injury to public health.

(Signed) J. E. WAKEFIELD,
Clerk of the Board.

The Under Secretary
of State for the
Home Department.

---

Local Government Board,
Whitehall, S.W.,
22nd May 1882.

SIR,

I AM directed by the Local Government Board to acknowledge the receipt of your letter of the 15th instant, No. A. $\frac{12786}{17^{a}}$, and to state that they have perused the papers forwarded therewith in relation to the application which has been made to Secretary Sir William Harcourt for an inquiry under sec. 31 of the Act 21 & 22 Victoria, cap. 104, with regard to the alleged nuisance caused by the discharge of sewage into the River Thames at Crossness and Barking Creek.

As regards the suggested postponement of the inquiry, I am directed to state that as the condition of the Thames at the outfall of the Metropolitan Board

of Works has been so often the subject of complaint, it seems to the Board impossible to avoid an investigation into the question; and if a commission is to be appointed for this purpose the Board consider it very important that they should be in a position to ascertain the actual state of the river during the summer months, when nuisance is most likely to arise.

The officers of the Metropolitan Board of Works have been persistent in the denial of the existence of any serious nuisance at the outfall, and for this reason the Board think it is essential that the inquiry should not be postponed until a date when the Commission will not be able to satisfy themselves by personal observation of the effect produced by the outfall works during the hot weather, but be compelled to rely exclusively upon the evidence of others.

The papers above referred to are returned herewith.

I am, &c.,
(Signed) JOHN LAMBERT,
Secretary.

The Under Secretary of State,
&c. &c. &c.
Home Office,
Whitehall, S.W.

---

Metropolitan Board of Works,
Spring Gardens, S.W.,
5th May 1882.

SIR,

REFERRING to Mr. Lushington's letter of the 19th April, in which he requests that the Board will give the Secretary of State a definite answer within a fortnight with respect to the alleged pollution of the river Thames by the sewage from the Metropolitan outfalls, I am to state that the Board still thinks some further delay desirable to enable it to continue through the summer months, when the process of decomposition is more rapid, the tests of the condition of the water, as unless this be done it may be alleged that the Board's tests do not fairly represent the condition of the river.

The memorandum of tests forwarded by the Home Office consists of extracts from various newspapers, commencing with one from the "Times" of October 24th, 1878, which records the opinion of the officers of the Woolwich Local Board that the passengers of the "Princess Alice" who were drowned were caused to vomit by the intolerably nauseous smells and state of the water.

In support of this allegation the quantity of organic matter in various samples of river water is quoted, as affording evidence of the presence of sewage. One sample was taken 50 feet from the northern outfall sewer whilst the sewage was running out of it, and another 20 feet from the southern outfall whilst it was also discharging, and the remark is made that the water was of a very offensive character. A report was made by the Board's consulting chemist in answer to these and other similar allegations, and a copy of this I am directed to forward for the Secretary of State's information. Subsequently by direction of the Board samples of the water were taken at various points from London Bridge to Erith, and the bed of the river near where the "Princess Alice" sank was examined and found to consist of clean gravel. Several persons drank of the water and found it free from taste or smell, the tide at the time being in the same condition as it was when the "Princess Alice" was wrecked.

It would not be possible in the short time named by the Secretary of State to answer the allegations contained in the memorandum *seriatim*. But many of them, particularly those relating to the quantity of sewage discharged from the outfalls and its relation to the volume of the tidal water, were answered in the course of the enquiry held before Sir Charles Hartley, Sir Frederick Bramwell, and Captain Galton on the alleged silting up of the Thames. The evidence then given, which has been printed by order of the House of Commons, is worthy of the attention of the Home Secretary.

I am further to state that the Board, guided by the opinions of men of science whom it has consulted, denies the allegations as set out in the memorial and memorandum forwarded to him.

Another fact of which the Secretary of State should be informed is, that the enlargement of the reservoir works at the outfalls which the Board proposes to carry out will have the effect of more completely confining the discharge of sewage to the period of the ebb tide, when it becomes so diluted by the immense volume of tidal water before it reaches any place where the banks are inhabited, that its presence in the water ceases to be capable of being detected by ordinary observation.

To prevent the flow of the rain water falling upon the Metropolis from flowing into the Thames is impracticable. To separate it from the sewage would involve the re-draining of every house in London, and the construction of new sewers in every street; pumping establishments would also have to be erected in various parts of the Metropolis; and to attempt to deodorise the sewage at the outfalls by any known process would involve a wasteful expenditure, and be accompanied by serious objections, without producing adequate advantages.

The Board is still of opinion that it would greatly aid the more complete investigation of the subject, if any inquiry which may be determined upon could be postponed until the month of October, so that samples might be taken from the river during the hot months of July and August; and the Board again submits this suggestion for the consideration of the Secretary of State.

I am, &c.,
(Signed) J. E. WAKEFIELD,
Clerk of the Board.

The Under Secretary of State for the Home Department,
Whitehall.

---

Whitehall,
25th May 1882.

SIR,

I AM directed by Secretary Sir William Vernon Harcourt to acknowledge the receipt of your letter and enclosure of the 5th instant, submitting, in behalf of the Metropolitan Board of Works, their denial of the allegations brought by the Corporation of London before him of an extensive and dangerous pollution of the water of the River Thames by the discharge of sewage from the Metropolitan main drainage system at Crossness and Barking Creek, and urging that if it is decided to direct an inquiry into the correctness of the allegations, it would be more likely to obtain fair results by being postponed until October next, and not made in the hot summer months when the decomposition is more rapid.

And I am to acquaint you, for the information of your Board, that Sir William Harcourt has considered the question carefully, and has arrived at the conclusion that, in the public interests, and in view of the numerous complaints publicly made on the same subject, it is clearly desirable that an inquiry should be held in pursuance of section 31 of the Act 21 & 22 Vict. c. 104, into the matter of the aforesaid complaint of the Corporation of London, and further that it would not be expedient that such inquiry should be postponed until a date when the Commissioners will not be able to satisfy themselves by personal observation of the effect produced at the outfall works during the hot weather, but be compelled to rely exclusively upon the evidence of others.

Under these circumstances Sir William Harcourt will shortly proceed to take the necessary steps for the appointment of a small commission to conduct the proposed inquiry, and he will cause a further communication to be adressed to your Board when the requisite preliminaries have been settled.

I am, &c.,

The Clerk to the
Metropolitan Board of Works.

App. K.

# APPENDIX K.

## Memorial presented to the Prime Minister.

To the Right Honourable William Ewart Gladstone, M.P., P.C., First Lord of the Treasury and Chancellor of the Exchequer, Elder Brother of the Trinity House.

The Memorial of the principal merchants, traders, and shipowners, and the representatives of the dock, wharf, and shipping interest on the River Thames, the owners of barges and the steam vessels engaged in the passenger traffic of that river, associated together and forming a general Committee for the protection of the Lower Thames from sewage, and whose names and descriptions are printed in the schedule attached to this Memorial.

Sheweth—

That at a general meeting of your memorialists, held on Tuesday, the 7th day of March last, the following resolutions were passed:—

1. That in the opinion of this Committee a Royal Commission should be appointed, or a parliamentary inquiry instituted, for the investigation of the present state of pollution of the River Thames from sewage, and the means to be taken to remedy this alarming and growing evil.

2. That an Executive Committee be now appointed and requested to take all necessary steps to give effect to the first resolution, and to adopt such other measures as may appear to them desirable in furtherance of the object in view.

That in pursuance of the last of the foregoing resolutions an Executive Committee, consisting of four members of the House of Commons and 22 gentlemen selected from the General Committee, was at the same meeting duly appointed for the purpose of giving effect to the said resolutions.

That in August last a petition complaining of the pollution of the River Thames from sewage was presented to the House of Commons by your memorialists and other persons to the number of 13,500 resident on the banks of the river, or connected with its trade, and praying for the adoption of measures to relieve the river of the sewage, but no action was taken thereupon in consequence of the late period of the session at which the petition was presented. The following is an abstract of the signatures to the petition:—

| | |
|---|---|
| Employés | 6,696 |
| Clerks and foremen | 669 |
| Professional and medical gentlemen | 127 |
| Baronet | 1 |
| Officers of army | 26 |

That "The Metropolis Local Management Act, 1858," which authorises the discharge of the Metropolitan Sewage at Barking and Crossness, was passed, as your memorialists are informed, under the belief, first, that the sewage discharged would not increase to the enormous extent it has done. Secondly, that the sewage would be deodorized before its discharge into the river, and thirdly, that the action of the tide in the river would have the effect of carrying the sewage water or matter into the sea instead of its remaining in the river, as is now the case, and being carried up and down between Gravesend and Blackwall, or points higher up the stream.

That the following statement shows the increase which has taken place between 1869 and 1878 in the quantity of sewage discharged at Barking and Crossness.

Sewage discharged at the Outfalls during Ten Years, 1869 to 1878 inclusive.

| Rainfall in Inches as observed at Crossness. | Year. | Gallons per Year. | | Remarks. |
|---|---|---|---|---|
| | | Crossness. | Barking Creek. | |
| 27·93 | 1869 | 17,574,292,274 | 12,793,513,197 | Low Level not completed. |
| 18·80 | 1870 | 16,678,226,567 | 14,633,751,920 | |
| 26·44 | 1871 | 18,497,165,385 | 20,112,148,713 | |
| 32·88 | 1872 | 22,281,418,356 | 23,137,747,554 | |
| 24·31 | 1873 | 21,878,839,124 | 22,680,778,594 | |
| 24·12 | 1874 | 20,544,185,537 | 22,610,777,770 | |
| 29·28 | 1875 | 23,505,775,239 | 26,955,262,659 | |
| 28·90 | 1876 | 22,370,124,831 | 27,951,403,034 | Western Pumping Station completed. |
| 29·26 | 1877 | 26,008,009,706 | 29,995,714,676 | |
| 29·26 | 1878 | 27,317,822,594 | 30,177,765,147 | |
| 271·27 | Ten years | 216,655,859,613 | 230,849,163,264 | |
| 27·1 | Average per year. | 21,665,585,961 | 23,084,916,326 | |
| Average per diem | | 59,357,769 | 63,246,346 | |
| Together | | 122,604,115=19,679,633 c. ft. | | |

That from the above statement it appears that in the 10 years ending 1878, with a practically uniform rainfall, the amount of sewage increased by about 89 per cent., and that the average daily flow in 1878 was 157,522,157 gallons, or 25,284,450 cubic feet, representing considerably over half a million tons of sewage.

That applying the ratio of increase during the last four of the said 10 years (14 per cent.) the quantity of sewage now being discharged into the river every 24 hours from the Crossness and Barking Outfalls is estimated at 180,000,000 gallons, or 30,000,000 cubic feet.

That "The Metropolis Local Management Act, 1858," contained provisions to the effect (sec. 23) that the Metropolitan Board of Works should, until its works required by that Act were completed, make use of proper means for deodorizing the sewage, or otherwise protecting the public health from any injurious consequences therefrom, and (sec. 24) that the said Metropolitan Board should cause the works to be executed under the Act, to be constructed and kept so as not to be a nuisance, and in deodorizing any sewage, and in disposing of any sewage or refuse from sewers, should not create a nuisance.

That although the said 23rd section may be construed as having application only to the period during which the works under the Act were in course of construction, the spirit and contention of the said 24th section is obviously to prevent the nuisance now complained of, although according to the legal construction of the words of the said section it does not supply the means of enforcing such intention.

That although Section 31 of the said Act empowers one of Her Majesty's Principal Secretaries of State to cause inquiry to be made into any complaints of any nuisance committed in respect of any of the matters referred to in Section 24, and to take steps to prevent or abate the nuisance, yet these provisions, your Memorialists are advised, would not permit of an inquiry as to whether the Act of Parliament which at present authorises the outfall of the sewage into the Thames at Crossness and Barking should not be repealed, and the sewage required to be carried to a point lower down the Thames, or to be deodorised and the effluent water alone be allowed to pass into the river.

That an application made under the 31st Section of the said Act to Her Majesty's Secretary of State for the Home Department by the Corporation of London, on the subject of the pollution of the Thames, has only led to the reference of such application to the Metropolitan Board of Works, aan thus the important subject is referred back to the authority of whose action your Memorialists now complain, and your Memorialists are afraid that no good will result therefrom, inasmuch as the Metropolitan Board of Works contend that no nuisance is created by means of their outfalls of sewage, and also for the reason that the question which your Memorialists require to be investigated is not within the legal construction of the said section.

That the Conservators of the River Thames have no jurisdiction upon questions of the pollution of water in the river caused by the outfalls or works of the Metropolitan Board of Works, such outfalls and works being specially exempted from the operation of the Rivers Pollution Act, 1876.

That in the year 1879 the Conservators, in an arbitration between them and the Metropolitan Board of Works, under the "Thames Navigation Act, 1870," endeavoured, but in vain, to raise the question of the pollution of the river from sewage, but they were met with the objection that the Act applied only to obstruction of navigation of the river, and the award in such arbitration, dated 24th April 1880, contained the following recital:—

> That, having regard to the powers conferred on us (meaning thereby the arbitrators) by the aforesaid Act of 1870, the said inquiry and our said report should be entirely confined to the consideration of the origin of the said three banks and as to their being obstructions to the navigation of the said river, and that the pollution of the said river by the flow of sewage at the outfalls as a sanitary question should not be gone into or considered by us in making our report.

That the Metropolitan Board contemplates an immediate further expenditure of 164,000*l.* for enlarging the outfalls at Crossness and Barking, which will not remedy the evil, and this outlay will be thrown away if, as the result of an independent inquiry, the necessity for the extension of the sewers to points nearer the mouth of the river be proved, or an effective system of deodorization determined upon.

That the magnitude of the evil complained of is one which requires immediate redress.

Your Memorialists therefore humbly pray—

> That Her Majesty's Government will be pleased to advise Her Majesty to grant a Royal Commission to inquire into and ascertain the present state of the River Thames as affected by the discharge of sewage into its stream and the effect thereof upon the lives and health of those of Her Majesty's subjects who live or have business on its banks, or who have to navigate the same, whether in vessels belonging to Her Majesty's subjects or to foreigners, and to advise as to the best means of putting a stop to a growing evil which seriously threatens the continued prosperity of the port of London.

And your Memorialists will ever pray, &c.

On behalf of your Memorialists,

(Signed) James Edwin Thorold Rogers,
Chairman of the Meeting of the General Committee, and Chairman of the Executive Committee.

---

The Schedule above referred to.

The names of the gentlemen and firms who have agreed in writing to form the General Committee for the Protection of the Lower Thames from sewage.

Captain J. E. F. Aylmer, M.P. for Maidstone.
Thos. Wm. Boord, Esq., M.P. for Greenwich.
Jas. Bryce. Esq., M.P. for Tower Hamlets.
Baron Henry de Worms, M.P. for Greenwich.
Arthur Cohen, Q.C., M.P. for Southwark, 6, Holland Park, W.
Aldermen Wm. Jas. R. Cotton, M.P. for London.
R. N. Fowler, Esq., M.P. for London.
Lord Geo. Hamilton, M.P. for Middlesex.
The Right Honourable J. G. Hubbard, M.P. for London.
The Right Honourable Viscount Lewisham, M.P. for West Kent.
Sir Chas. Mills, Bart., M.P. for West Kent.
Chas. J. Ritchie, Esq., M.P. for the Tower Hamlets.
Professor Jas. E. T. Rogers, M.P. for Southwark.
Sir Sidney Waterlow, M.P. for Gravesend.
Lord Henry Lennox, M.P. for Chichester.
John Orrell Lever, M.P. for Galway.

Anderson, Brothers, Merchants, 16, Philpot Lane, E.C.
Anderson, W., Chairman Local Board, Erith.
Armstrong, J. C., Mayor of Gravesend.
Anderson, Anderson, and Co., Orient Steam Navigation Company, 13, Fenchurch Avenue, E.C.
Adamson and Ronaldson, Shipowners, 34, Leadenhall Street, E.C.
Arnold, G. E., Wharfinger, &c., Woolwich.
Asser, Robert V., Belvedere Park, Kent.
Bennoch, Francis, Director, London Steamboat Company, Member Conservancy Board, &c.
Beale, Charles, Erith.
Bradn, Frederick, Crosby Row, Borough, S.E.
Bellamy and Co., King and Queen Granaries, Rotherhithe Street, S.E., and 6a, Fenchurch Buildings, E.C.
Boulcott, J. and Co., Limehouse.
Beck and Pollitzer, Wharfingers, Upper Thames Street.
Brown, Jas. and Alexr., Shipowners, &c., 9 and 11, Fenchurch Avenue.
Baxter, F., Manager, South-eastern Bonded Warehouses and Wharf Co., Southwark.
Bernays, Herbert L., M.R.C.S., Medical Officer of Health, Charlton.
British India Steam Navigation Company, Limited, per P. Macnaughtan, Esq., Secretary, 13, Austin Friars, E.C.
Cape, George Augustus, Chairman School Board, Erith.
Chaytor, D. A., Coal Factor, 155, Fenchurch Street, E.C.
Chambers, Brothers, 40, Seething Lane, E.C.
Churchill and Sim, 29, Clement's Lane.
Corner, F. M., Medical Officer of Health, Poplar.
Clarke, Stephenson, and Co., Shipowners, &c., 4, St. Dunstan's Alley, E.C.
Collingridge, William, Medical Officer of Health, Port of London.
Cunis, W. R., Lighterman, Lambeth.
Corfield, W. H., M.D., Medical Officer of Health, St. George's, Hanover Square.
Crook, John Evelyn, M.D., Medical Officer of Health, Northfleet.
Cousens, John S., Wharfinger, &c. Millwall Docks, E.
Corbet, R., Medical Officer of Health, Orsett, Essex.
Collier, W. E., Medical Officer of Health, Fulham District.
Chapman, F. W., 46, Gedling Street, Dockhead, E.C.
Dinham, C., Shipowner, Coal Exchange.
Denny, Thomas R., Old Corn Exchange, Mark Lane, E.C.
Deacon, H. T., Lighterman, Limehouse.
Ducas, Thomas, Lighterman, 241, East India Road, Poplar.
Fisher, Wm. Alexr. Fisher's Sufferance Wharf, Rotherhithe Street, S.E.
Fortescue, N., Bridge Wharf, Blackfriars.
Fitzgerald, E. G., Timber Merchant, Lambeth.

App. L.

## APPENDIX L.

### Letter from Capt. Burstal to Sir Benjamin Hall.

(Metropolitan Sewage Discharge Commission.)

32, Abingdon Street, Westminster,
Sir, November 18th, 1856.

On remarking upon the points of outfall for the sewage of the metropolis, I beg to inform you that the conclusions to which I have arrived relative to the drift of the stream are from the observations I made on the river in June last, from which I estimate the drift during the last 1½ hour of the flood tide to be 3¾ miles at springs, and 3 miles at neaps; consequently the water which passes point B. at ½ a mile below the Half Way House will (during springs) reach the town of Woolwich before it is arrested by the ebb stream, and at neaps ¼ mile below the Royal Arsenal.

I should, therefore, submit that the nearest point to London at which the outfall be made (so as to be at all times certain that the first portion discharged at 1½ hour before high water would not flow in or near the inhabited part of the metropolis) be in the upper part of Erith Reach, 15 miles from London Bridge, ½ mile from Erith Church, and ¾ mile below Jenningtree Point, nearly opposite Rainham Creek. From this, as a point of outfall, commencing at 1½ hour before the time of high water there, the upper portion of the sewage would at springs be opposite Barking Creek, and at neaps off the Magazine in the lower part of Barking Reach, near the metropolitan boundary. It cannot, therefore, be said that even from this position the sewage would be perfectly clear of the eastern limit

of the metropolis at spring tides, but it is certainly far enongh from any inhabited district to guarantee that (with those long floods caused by north and north-west winds) the river would not be polluted in the vicinity of Woolwich.

The additional length of drain necessary to be constructed to this outfall is exactly 1 mile, the space of river above the outfall thus freed from sewage would be $1\frac{7}{8}$ mile.

For similar reasons to those above stated, I would beg to suggest that the outfall on the north side be at Rainham Creek, which would be an extension of mile beyond that proposed.

With reference to the time that the pumping of sewage into the river should cease, I would state that the water which passes the outfall at 3 hours after high water will be carried 8 miles down, and back by the return flood about 13 miles, or 5 miles above the outfall, therefore the latest period at which that process should be admitted is something short of 3 hours after the time of high water; it therefore becomes necessary, if a period of 4 hours is requisite for the discharge of the sewage from the reservoir, supposing that reservoir is of sufficient capacity to contain it all, it stands to reason that the period of discharge should commence at least $1\frac{1}{2}$ hour before the time of high water.

If, however, it should appear that the capacity of the reservoir is not such as will contain the whole of the sewage that may arrive from the metropolis between the one period of discharge and the next, the dimension of the reservoir must be enlarged to meet the requirement.

I beg also to call your attention to the fact that when it was proposed to have the outfall at A. (within the metropolis) the reservoir was to contain 4,000,000 cubic feet; it is now proposed to have the outfall at B. in Half-way Reach, and the reservoir when full is to contain only 1,764,000 cubic feet and to cover a space of $4\frac{1}{2}$ acres.

On this, the south side of the river, for which the above provision is made, the amount of sewage is calculated by Mr. Bazalgette at $1\frac{1}{4}$ million cubic feet.

On the north side of the river Mr. Bazalgette states the amount of sewage to be six million cubic feet, whilst the reservoir proposed there is to be only double the size of that on the south side; in this there is a discrepancy of proportion, because the area of the reservoir on the north side of the river is to be 9 acres, and consequently 2 to 1; the amount of sewage is 6 million cubic feet, therefore 5 to 1.

In cases of heavy rains it would be necessary to provide for the great accumulation of water which would run into the drain, either by outlets or a larger reservoir: in the first instance the surplus quantity would flow into the Thames at various places, carrying with it a portion of sewage in solution; and in the last, immediately on the appearance of an extra supply in the reservoir, it would be imperative to commence pumping irrespective of the time of tide.

I have, &c.
(Signed) Edward Burstal,
Commander R.N.

The Right Hon.
Sir Benjn. Hall, Bart, M.P.
&c. &c. &c.

## APPENDIX N.

Correspondence, &c. received from the Thames Conservancy Board, July 1882.

Thames Conservancy,
Harbour Master's Office,
17th July 1879.

Sir,

I have the honor to report that in rowing up the north shore of the river at three-quarters ebb on the 26th June last at 11.30 a.m., on approaching the Storm Outlet at Ratcliff Cross I encountered a great quantity of sewage matter of the worst possible kind issuing from that outlet. It could not have been worse if we had been in the sewer itself.

The time was just below low water, and, as a natural consequence, all this excrement would be carried up the river with the flood tide, polluting and being deposited in the higher reaches.

I beg to state I called the attention of the Sanitary Inspector's launch to the matter, and they proceeded to take a sample.

I have, &c.,
(Signed) Richard Marsden.

To Captain Burstal,
Secretary,
Thames Conservancy.

---

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
23rd July 1879.

Dear Sir,

I am directed by the Conservators of the River Thames to transmit herewith, for the information of the Metropolitan Board of Works, a copy of a report they have received from Capt. Marsden, their deputy harbour master, to the effect that sewage was discharged into the river from the Storm outlet at Ratcliff Cross at three-quarters ebb, on the 26th ultimo, at such a time that it would be carried up the river on the flood tide.

I am, &c.,
(Signed) E. Burstal.
Secretary.

The Clerk of the
Metropolitan Board of Works.

---

Thames Conservancy,
Harbour Master's Office,
Woolwich Dockyard,
16th July 1880.

Dear Sir,

The river water every day and night during the last month has been heavily charged with sewage; the odour even as far as Blackwall is worse than I have ever known it. The water last Monday at nearly half flood was so bad that I landed at the southern outfall to ascertain if the sluices were not open.

The foreman assured me they were closed. I can only say that immediately below the works the water was comparatively clear, and the air was almost free from the smell of sewage, but the nuisance still continues to be felt, and is spoken of on all sides.

Believe, &c.,
(Signed) J. Fitzgerald,
Harbour Master,
Central District.

Captain Burstal, R.N.,
41, Trinity Square.

---

Thames Conservancy,
Harbour Master's Office,
Woolwich Dockyard,
25th July 1880.

Gentlemen,

Since my last report on the state of the river the water has become much worse, and it is now so heavily charged with sewage matter that it cannot be used for the decks, or even in the cisterns, and has become a public nuisance.

I have frequently traversed the river of late from side to side for the purpose of ascertaining its real state, and I have to report that throughout the whole length of my district (from Greenwich to Greenhithe) the water has been foul, and from Erith upwards the water is crowded with sewage at all times of tide.

The stream between Halfway Reach and Woolwich is nearly black at half tide both on the flood and ebb, and I have no hesitation in describing it as little better than an open sewer in this part of the river.

At the top of high water sewage is present in all directions, which is quite a new feature in my experience.

Yesterday off Greenwich at high tide the river was full of sewage, and the stench abominable; how far it extends upward I cannot say.

Occasionally streaks of apparently clear water are visible at the top of the tide, but it is only surface deep, since in the wake of every steamer a line of sewage can be traced which has been stirred up from underneath. The river has not been in its present condition, within the experience of anyone I have met, since the opening of the Metropolitan Works at Barking and Crossness, and I attribute it to three causes, chief of which is the discharge of sewage on the flood tide; it is no secret that this frequently takes place during the prevalence of rain, at which times the culverts and reservoirs become too heavily charged.

Secondly, the young flood tide disturbs the surface matter which has been deposited on the banks and

App. N.

foreshores during the preceding ebb, and sweeps it up the river.

And lastly, the sluicing operations at Victoria Docks (new entrance) contributes its share. These operations must of necessity be carried out at low water and repeated periodically. The matter thus disturbed from the bed of the river is also swept up by the following flood tide.

It is my opinion that the present filthy state of the river calls for the immediate attention of the Port Sanitary Authorities.

I have, &c.,
(Signed) J. Fitzgerald.
Harbour Master,
Central District.

To the Conservators of the River Thames.

---

Thames Conservancy,
Harbour Master's Office,
41, Trinity Square,
26th July 1880.

Sir,

I have the honor to report for the information of the Board that the river on the flood tide on Saturday 24th instant was in a very bad state, the water black and full of filthy black-looking matter in suspense, and giving forth a most disagreeable smell. At Millwall it got worse; and off Port of London Wharf and as far as East Greenwich at three-quarter flood and up to high water the odour was horrible and sickening. I was engaged there for some little time about a launch, and the effect was felt by all the crew of my boat.

I have, &c,
(Signed) Richard Marsden,
Deputy Harbour Master.

Captain Burstal, R.N.,
Secretary,
Thames Conservancy.

To the Conservators of the River Thames.

---

*Private and Confidential.*

Port of London Sanitary Office,
Deptford, S.E.,
27th July 1880.

Dear Sir,

I wish to call the attention of the Conservators of the River Thames to the extremely unsatisfactory state of the water at the present time.

As you are aware this authority has no actual power nor jurisdiction in the matter, but we cannot fail to realize the fact that, unless the condition of the river materially improves, any continued hot weather will almost certainly cause a serious outbreak of disease, the work consequent on which must obviously fall upon our heads, and for which (though utterly powerless to prevent it) we shall to a great extent be held to blame.

For many days the water has been of dark colour and foul smell, though it varies very much from time to time.

I have examined samples in many places when thus bad, and have found them to be simply "diluted sewage." How far this is due to the Metropolitan Board of Works outfalls is a question which of course cannot be at once decided upon.

I take this opportunity of simply informing you privately of the *facts*, and shall be glad to hear of anything which will tend to check this very serious evil.

It occurred to me that if the Conservators were about to take action in any form any information or assistance would be of service.

I am, &c.,
(Signed) W. Collingridge,
Port Medical Officer.

To the Conservators, of the Thames.
Capt. Burstal, R.N.

The worst parts of the river *at present* are Woolwich, Erith, and Cherry Tree Point.

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
8th September 1880.

Dear Sir,

I have laid your letter of the 27th July last before the Conservators of the River Thames, who desire me to thank you for the communication, and to suggest you should lay your statement before the Metropolitan Board of Works.

Yours, &c.,
(Signed) E. Burstal,
Secretary.

W. Collingridge, Esq.,
Port Medical Officer,
Deptford.

---

"Warspite," Woolwich,
27th July 1880.

Dear Sir,

I think it my duty to report, for the information of the Committee, the bad state of the river where this ship is lying. It is no exaggeration to say that for several days past the whole river has been neither more nor less than an open sewer, the water of a dark slate colour, and large masses of solid sewage floating past. I communicated with Dr. Collingridge, the medical officer of the port of London, and also with the harbour master, sending them samples of the water from alongside. I have had visits from both those officials, who entirely concur in what I report. Dr. Collingridge said that he had analysed the water which I sent him, and found it to be "slightly diluted sewage." There is no doubt in my mind that the sluices at the outfall have been opened some hours before high water, as I have observed the whole river black with sewage at or about half-flood tide. I would suggest that a letter be sent to the Metropolitan Board of Works that they may take steps to forbid the sluices being opened while the tide is flowing, in order, if possible, to abate this horrible nuisance, which, if continued, must, I fear, cause a serious outbreak of sickness.

I am, &c.,
(Signed) A. W. Gillett,
Captain, R.N.

The Secretary,
Marine Society.

---

1, Peveril Street,
Battersea,
7th December 1880.

Sir,

I beg to inform you that the sewers next below London Bridge, at Dowgate, at Saint Paul's, at Blackfriars, and the pumping station Grosvenor Road, were discharging very offensive matter into the river on the 6th and 7th instant.

I have observed this on several occasions during the past week, the discharge prevailing from half ebb and on the young flood.

I am, &c.,
(Signed) H. Little,
Inspector.

Captain Burstal, R.N.,
Secretary.

---

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
16th December 1880.

Sir,

I am directed by the Conservators of the River Thames to forward herewith a copy of a report which has been received by them from their River Inspector, Mr. H. Little, in which he calls attention to the discharge of offensive matter into the river from the sewers next below London Bridge, at Dowgate, at Saint Paul's Pier, at Blackfriars, and at the pumping station Grosvenor Road, Pimlico.

I am further to call your attention to the fact that this discharge occurred after a long continuance of dry weather, and to request that you will bring the subject under the consideration of the Metropolitan Board of Works with a view to ascertaining whether they are prepared to take any steps to prevent the discharge of sewage into the river from the sewer outlets above-named.

I am, &c.,
(Signed) E. Burstal,
Secretary.

The Clerk of the Metropolitan Board of Works.

---

Thames Conservancy.
Harbour Master's Office,
5th July 1881.

Sir,

I beg to inform you that the water of the river is this day very offensive on the ebb, more particularly so at high water this morning.

I am, &c.,
(Signed) C. H. James,
Harbour Master.

To Captain Burstal.

---

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
14th July 1881.

SIR,

I HAVE to inform you that the water of the river was very dark, discoloured, and offensive this day towards high water.

I am, &c.,
(Signed) C. H. JAMES,
Harbour Master.

Captain Burstal.

---

Thames Conservancy,
Harbour Master's Office,
Woolwich Dockyard,
20th July 1881.

DEAR SIR,

I FEEL it my duty to bring to the notice of the Conservators the present state of the river within my district. During the past week it has been in a very filthy state, and I fear there is every prospect of its continuance. The river between Purfleet and Charlton more especially is heavily charged with sewage matter, which is visible at all times of tide, and its sickly odour pervades every part of the district.

Yours, &c.,
(Signed) J. FITZGERALD,
Harbour Master,
Central District.

Captain Burstal, R.N.,
41, Trinity Square,
London.

---

Trinity House, London,
21st July 1881.

DEAR SIR,

I BEG to draw your attention to the filthy state of the river between Blackwall and Tripcock Point. I slept on board the "Galatea" on Sunday night last, and was obliged to close the scuttle, owing to the smell of the water passing the paddles. There was no mistaking it for that of the chemical works, and the water was quite black. Everybody I met was complaining bitterly about the state of the river.

I am, &c.,
(Signed) WM. WOOLCOTT.

To Admiral
Sir F. Nicholson, Bart.

I beg you will make use of my name in this matter if you think fit.

(Signed) W. W.

---

Port of London Sanitary Offices,
King William Street, Greenwich, S.E.,
21st July 1881.

SIR,

I WISH once more to call the attention of the Thames Conservancy (as the guardians of the river) to the extremely foul and filthy state of the water at the present time.

During the hot days we had last week and the beginning of this week the odour has been very bad indeed, especially at high tide, and during the first part of the ebb.

This authority has done much to improve this by closing and diverting foul outfalls, but is now advised that it has no jurisdiction in the matter, such power resting with the Thames Conservancy. Under these circumstances I felt it a duty to call your attention to a condition of affairs which, if hot weather continue, may at any time lead to a serious outbreak of disease.

Yours, &c.,
(Signed) W. COLLINGRIDGE,
Port Medical Officer.

To the Secretary,
Thames Conservancy,
Captain Burstal, R.N.

---

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
27th July 1881.

SIR,

I HAVE laid your letter of the 21st instant before the Conservators of the River Thames, who have ordered a copy of it to be sent to the Metropolitan Board of Works, in whose jurisdiction the sewage is which causes the pollution referred to by you.

I am, &c.,
(Signed) E. BURSTAL,
Secretary.

W. Collingridge, Esq.,
Port Medical Officer,
Port of London Sanitary
Authority, Greenwich.

---

Thames Conservancy,
41, Trinity Square, E.C.
27th July 1881.

SIR,

THE Conservators of the River Thames having received several representations of the contaminated condition of the river water during the year 1880 and the present year, especially during the hot and dry weather in the month of July, have directed me to send copies of the letters containing these representations for the information of the Metropolitan Board of Works.*

I am, &c.,
(Signed) E. BURSTAL,
Secretary.

The Clerk of the
Metropolitan Board of Works.

---

The London Steamboat Company,
Adelaide Buildings (Limited),
London Bridge, 25th July 1881.

DEAR SIR,

WE have lately had so many complaints from our captains, as well as from passengers by our steamboats, that we now send you from our lessees a formal complaint setting forth the facts referred to in language unmistakeable. It is difficult to fix responsibility, but, as conservators of the river and protectors of the navigation, we appeal to you, and trust you will exercise your powerful influence in securing a remedy for these evils.

Yours, &c.,
(Signed) GEO. WM. LAKEMAN,
Secretary.

Captain Burstal, R.N.,
Secretary, Thames Conservancy.

(For copy of a letter herein referred to, see next sheet.)

---

Thames and Channel Steamship
Company (Limited),
Adelaide Buildings,
London Bridge,
25th July 1881.

DEAR SIR,

I BEG to request you will communicate with the Thames Conservancy Board as to the filthy state of the river below bridge, more particularly about Woolwich. The effluvia thrown off by the sewage floating up and down in the stream is positively poisonous, the river being for miles black with it. As an instance, yesterday morning at 10 o'clock the passengers on board the "Eclair" at Woolwich were seriously annoyed; the smell was almost unbearable.

I am sure it is very detrimental to our interests, and appears to be caused by the discharge being made into the river on the flood instead of the ebb tide. I trust you will use your best endeavours to have this nuisance remedied.

Yours, &c.,
(Signed) J. R. PEARSON,
General Manager and Secretary.

The Chairman,
London Steamboat Company.

London Steamboat Company, 25th July 1881.
Thames and Channel Steamship Company, 25th July 1881.
Trinity House, Captain Woolcott, 21st July 1881

App. N.

Reach, 30 yards off the northern outfall, 2¾ hours before high water. Received from the Hon. the Conservators of the River Thames on the 22nd August 1881.

I certify that I have examined the above sample, and that the following are the results:—

*Physical Characteristics.*

Action on test paper, faint alkaline.

Amount of alkalinity calculated as carbonate of soda, 37·10.

Smell, offensive of sewage.

Sulphuretted hydrogen, heavy.

Suspended matter, heavy.

Appearance of suspended matter, black, flocculent, and earthy.

Appearance of sample before filtration, black, thick from suspended matter.

Appearance of sample after filtration, brownish-yellow, slightly opaque.

Hardness before boiling, 21°·5, Clark's scale.

*Chemical Results.*

| | Grains per Gallon. |
|---|---|
| Suspended matter: | |
| Volatile organic matter | 80·90 |
| Mineral matter | 185·10 |
| Total | 266·00 |
| Dissolved matter: | |
| Volatile organic matter | 22·80 |
| Mineral matter | 168·80 |
| Total | 191·60 |
| General composition of mineral matter: | |
| Lime combined as salts | 10·08 |
| Chloride of sodium (common salt) | 143·32 |
| The dissolved organic matter contained— | |
| Nitrogen as ammonia | 1·9990 |
| ,, albuminoid ammonia | ·1260 |
| And absorbed oxygen from permanganate equal to | 1·3330 |

*Microscopical Results.*

Animal and vegetable débris in excessive quantity. Hairs, animalculæ, and vegetable spores of various species, such as vibriones spirillum, acomia paramecia, desmids confervaceæ. General appearance of sewage matter.

*Opinion.*

This sample is simply diluted sewage. There is some salt water mixed with it, and doubtless a small proportion of fresh river water also; but as far as concerns its offensive character and liability to cause deposit of decomposing matter, it is as bad as average London sewage.

(Signed) G. W. Wigner, F.C.S., F.I.C.

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
14th September 1881.

Sir,

I am directed by the Conservators of the River Thames to transmit herewith a copy of a report of an analysis made by Mr. Wigner, F.C.S., of a sample of fluid taken from the river in Barking Reach, 30 yards off the northern sewage outfall, on the 19th ultimo, 2¾ hours before high water, and I am to request that you will bring the same under the consideration of the Metropolitan Board of Works.

I am, &c.,
(Signed) E. Bursтal,
Secretary.

J. E. Wakefield, Esq.,
Metropolitan Board of Works.

---

Local Government Board,
Whitehall, S.W.,
3rd November 1881.

Sir,

I am directed by the Local Government Board to transmit to you, for the consideration of the Conservators of the River Thames, the accompanying copy of a letter which the Board have received from the vestry of Plumstead, containing a copy of a resolution passed by them with regard to the pollution of the River Thames by sewage from the works executed under the Metropolis Local Management Acts.

At the same time I am to state that the attention of the Board has also been drawn to the alleged nuisance occasioned by the works in question by an influential and representative deputation from the locality.

The Board are desirous, therefore, of being furnished with the observations of the Conservators on the subject.

I am, &c.,
(Signed) Walter J. Sendall,
Assistant Secretary.

---

Plumstead,
20th September 1881.

Sir,

I am requested to forward a resolution passed by the vestry of Plumstead at their meeting on the 18th instant:—

"That this vestry expresses its abhorrence at the continued impurities from sewage existing in the Thames near the metropolis, contrary to the 135th section of the Metropolis Local Management Act, 1855, and that this resolution be forwarded to the Local Government Board, with an earnest hope that it will concert measures to remedy the evil complained of."

I have, &c.,
(Signed) Edwin Hughes,
Vestry Clerk.

To the Secretary to the
Local Government Board.

---

Thames Conservancy,
41, Trinity Square,
Tower Hill, E.C.,
16th November 1881.

Sir,

I am directed by the Conservators of the River Thames to acknowledge the receipt of your letter of the 3rd instant (No. 89,921 K. (1)), with its enclosure, being a copy of a resolution passed by the vestry of Plumstead on the 18th September last, on the subject of the polluted condition of the river, said to be caused by the impurities passed into it from the sewage outfalls.

In compliance with the request contained in your letter that the Conservators would furnish the Local Government Board with their observations on this subject, I am to state that the Conservators are fully aware of the contaminated state of the river and the offensive odour arising therefrom during the summer months; that letters have been addressed by them to the Metropolitan Board of Works, enclosing copies of reports on the subject. The Conservators beg to refer you to the concluding paragraphs of their report to Parliament, dated 25th July, wherein this subject is prominently referred to; also to the minutes of evidence given before the umpire and arbitrators in 1879, when the question relating to mud deposits in the river was brought before them, in which the witnesses referred in strong terms to the offensive state of the river, caused by the sewage that was passed into it from the outfalls at Barking and Crossness; but as that inquiry was based upon sections 20 and 21 of the Thames Navigation Act of 1870, the question of pollution of the river did not come within the scope of it.

In order that you may readily see what has been received by the Conservators on the subject referred to in this letter, an extract from the report to Parliament and copies of letters and reports are herewith enclosed, as named in the accompanying list.

I am, &c.,
(Signed) E. Bursтal,
Secretary.

The Assistant Secretary,
Local Government Board,
Whitehall, S.W.

---

Extract from the Conservators of the River Thames Annual Report to Parliament, dated 25th July 1881.

During hot weather, when there has been little rainfall, complaints of the pollution of the river within and below the metropolitan district frequently reach the Conservators.

The pollution thus complained of is indicated by the offensive odour and highly discoloured state of the water. It must be remembered that Kingston and Richmond, and other places below the intakes of the water companies, still pass their sewage into the river, the penalties for their doing so having been suspended

by the Legislature to give time for overcoming the difficulties of carrying out a complete sewage system for this district.

Although the discharges from these places may in some degree affect the purity of the river near the metropolis, it can hardly be doubted that the chief cause of the polluted state of the river within and below the metropolis arises from the discharge at the outfalls and storm outlets of the Metropolitan Board of Works, in whose district ordinary sewage is exempted from the provisions of the purification section in the Conservancy Acts.

Mr. James C. Walker, pilot, Nos. 2654–62, 2734–36, 2739–43.
Mr. J. H. Cavill, pilot, Nos. 2781–84.

---

Extracts from the Harbour-Master's Journal (Central Station) for the Years 1878–81.

1878.

20 Dec.—Tides very sluggish, owing to which the water in Halfway Reach, and also in Barking Reach, was found to be in a very foul state and heavily charged with sewage.

1879.

2 Jan.—Tide sluggish. Water in Halfway Reach heavily charged with sewage matter.

16 July.—Watchman on board steamer "Conservator" at Charlton reports a strong smell of sewage round the vessel on the flood tide.

19 July.—A strong smell of sewage round the vessel at her moorings, and the water presenting all the appearances of being charged with sewage matter.

1880.

24 June.—A smell from the river water most offensive, which continued the entire day. The stream, both on flood and ebb, apparently charged with sewage.

25 June.—A smell of sewage pervaded the river from Charlton to Erith, quite as bad as on previous day.

26 June.—Smell from river water still offensive, but not so bad as yesterday.

6 July.—A very offensive smell from the river water in the lower part of the district, especially in Erith Reach, although the water was comparatively clear.

7 July.—River smelling very badly in Erith and Halfway Reaches, and a good deal discoloured with sewage below Barking Creek.

9 July.—River water much discoloured and smelling badly.

11 July.—River water strongly impregnated with sewage and smelling badly.

12 July.—Landed at southern outfall this day at half flood to complain of the state of the river. Was informed that the sluices had been opened at the usual time;—a statement which I was inclined to doubt, owing to the river water below the works being comparatively clear and the air free from sewage taint; whereas in Barking Reach and immediately above the works it was just the reverse.

13 July.—River water in a very bad state off Charlton and Woolwich.

15 July.—River water greatly discoloured with sewage in Bugsby's and Blackwall Reaches, and smelling very badly.

17 July.—The river to-day on the ebb and up to the following half flood, between Woolwich and Erith, was in a worse condition than I have ever known it. The water throughout the above-mentioned part of the river was heavily charged with sewage from side to side, and the stench almost unbearable.

18 July.—River in Woolwich Reach almost black with sewage matter.

19 July.—River water much clearer on the surface to-day, but very thick inshore.

21 July.—River water this day fairly clear on surface, but filthy and stinking underneath, every steamer leaving discoloured water in her wake. Just above Leather Bottle Point the water was nearly black at the last quarter flood, covering a space of nearly a mile.

22 July.—River in filthy condition between Charlton and Erith. Sewage apparently working its way higher up the river.

23 July.—River between Charlton and Erith in filthy condition at low water, and the stench abominable. Stream during whole flood heavily charged with sewage matter from side to side, nearly black in some places, and the river, even at high water, above Greenwich, full of sewage, and the odour disgusting.

24 July.—River water on surface at high water a little improved from previous day.

25 July.—River to-day again in a beastly state. William Turnnidge, of "Conservator," attributes his illness to the state of the river.

26 July.—At low water this day the river from Bugsby's down to Barking Creek was choked full of sewage, landing places and foreshores covered with it; stench abominable. The same on flood. Slightly better at high water, but on the ebb a strong smell of sewage present right across the river off Woolwich, the water becoming thicker as the tide fell.

27 July.—River water tolerably clear at high water this day; black streaks and patches visible at first quarter ebb.

28 July.—River water improved in appearance off Charlton, but full of sewage in Barking and Halfway Reaches at half ebb. Patches of sewage all over Long Reach, and smelling strong.

29 July.—Water in river rather better than on the previous day, owing to the prevalence of strong westerly winds. Surface water fairly clear and free from smell.

30 July.—Water in the river continues to improve, but the foreshores and some of the landing places and wharves are clothed with sewage mud.

31 July.—River continues to improve.

4 Aug.—River to-day much improved and free from smell, excepting in Halfway Reach.

5 Aug.—River water fairly clear and free from smell.

13 Aug.—River water this day smelling badly. Patches of sewage visible throughout this whole district, from Greenwich to Queenhithe, especially on first quarter flood.

20 Aug.—Water in river remains fairly clear and free from bad odour.

21 Aug.—River water moderately clear, but smelling badly at low water.

27 Aug.—River water throughout the district, both on ebb and flood, smelling strongly and of sewage; black patches to be seen in various parts.

14 Oct.—River water heavily charged with sewage matter this day, especially in Erith and Halfway Reaches. Air bubbles visible right across the river at low water.

1881.

14 July.—River water heavily charged with sewage and smelling badly.

18 July.—River this day very offensive and heavily charged with sewage.

19 July.—River this day in filthy condition, especially between Blackwall and Purfleet.

20 July.—River in a very bad state.

23 July.—River in an exceedingly bad state, even at high water.

25 July.—River water in filthy condition at half ebb, and stench most offensive.

26 July.—River at half ebb in a filthy state, being heavily charged with sewage.

27 July.—River still heavily charged with sewage.

App. N.

28 July.—River water very filthy this day, especially off Erith and Woolwich.
30 July.—River water this day rather better, and the smell not quite so offensive.
2 Aug.—River again very filthy at half tide, and the odour very offensive.
5 Aug.—River remains very filthy and full of sewage.
6 Aug.—River remains very filthy and full of sewage.
8 Aug.—River water this day somewhat improved in appearance, and not smelling so badly.
9 Aug.—Same as on previous day.
10 Aug.—River water in a filthy state on the ebb tide, especially in Halfway Reach and off Erith.
12 Aug.—River heavily charged with sewage, and smelling badly at half flood.
21 Aug.—Two hands at northern outfall, Barking Reach, at half flood (night tide), reports sewage coming through the sluices at 9.30 p.m. High water at 11.35 p.m. Geo. Lamerton and Thos. Long in the boat.

---

Thames Conservancy,
Deputy Harbour Masters Office,
Limehouse,
6th July 1882.

Sir,

I beg to report to you that as I rowed past the following storm outlets this morning at 10.30, last quarter ebb, viz., Ratcliff Cross, Bell Wharf, and Coal Stairs, I passed through an immense quantity of bonâ fide sewage, and that the smell from it was most offensive.

I am, &c.,
(Signed) L. Bowen.

To Captain Burstal, R.N.
Secretary,
Thames Conservancy.

Extract from the General Report of the Conservators of the River Thames, from 1st January 1880 to 31st December 1880.

The periodical surveys of the river having shown that shoals had been formed in Halfway Reach since the opening of the Metropolitan sewage outfalls, the Conservators deemed it advisable that an inquiry should be held under sections 20 and 21 of the Conservancy Act 1870. That inquiry was limited to the question, whether a sufficient obstruction to the navigation had been caused to render the Metropolitan Board of Works liable for the removal of such obstruction.

This question the umpire and arbitrators decided in the negative.

It should be noticed, however, that the question of the pollution of the river could not be raised in this inquiry under the sections of the Act of 1870.

During hot weather, when there has been little rainfall, complaints of the pollution of the river within and below the Metropolitan District frequently reach the Conservators. The pollution thus complained of is indicated by the offensive odour and highly discoloured state of the water. It must be remembered that Kingston and Richmond, and other places below the intakes of the water companies, still pass their sewage into the river, the penalties for their doing so having been suspended by the legislature, to give time for overcoming the difficulties of carrying out a complete sewage system for this district.

Although the discharges from these places may in some degree affect the purity of the river near the Metropolis, it can hardly be doubted that the chief cause of the polluted state of the river within and below the Metropolis arises from the discharge at the outfalls and storm outlets of the Metropolitan Board of Works, in whose district ordinary sewage is exempted from the provisions of the purification sections in the Conservancy Acts.

## APPENDIX O.

Reports from the Officers of the Woolwich Local Board of Health, 1878.

Woolwich Local Board of Health.

Reports of the Surveyor and Analyst to the Woolwich Local Board of Health on the State of the Water of the River Thames. Presented to the Board on the 22nd October 1878, and ordered to be printed.

---

The State of the River Thames.

At a Meeting of the Woolwich Local Board of Health, held at the Town Hall, Woolwich, on Tuesday the 8th day of October 1878,

Present,

John Taylor, Esq., Chairman, and 13 other members,

It was moved by Captain Behenna, R.A., seconded by S. C. Harrington, Esq., and resolved unanimously—

"That the surveyor be instructed to take samples of the water of the River Thames, at various points and depths, when the tide is about in the same state as when the accident occurred to the 'Princess Alice' steamboat, and that such samples be forwarded to Mr. Wigner, the Public Analyst, for analysis and report."

(Extracted from the Minutes of Proceedings.)
Andrew C. Reed,
Clerk to the Board.

---

Report of H. O. Thomas, Assoc. Inst. C.E., Surveyor to the Woolwich Local Board of Health, on the State of the Water of the River Thames. Presented to the Board on the 22nd October 1878, and ordered to be printed.

*To the Woolwich Local Board of Health:—*

Gentlemen,

I beg to report that, in compliance with your instructions of the 9th instant to take samples of Thames water at a time of day and condition of tide corresponding as near as possible with the circumstances which prevailed when the accident to the "Princess Alice" occurred, and to obtain the water at various depths, I procured the loan of a steam launch from the Thames Conservancy Board, and on Monday, the 14th instant, accompanied by your analyst, Mr. Wigner, I left London Bridge a little before 3 o'clock, and obtained samples of Thames water at the places mentioned in the annexed schedule. The tide was high at London Bridge on this day at 3.15 p.m.

At every chosen place two samples were taken, one as near to the surface as could be (care being taken to avoid the scum on the surface), and the other sample at about half the depth of the river.

No. 10 was taken as near as possible to the spot where the wreck of the "Princess Alice" was found, and from nearly, but not quite, the bottom of the river.

All the samples, unless otherwise specified, were taken as nearly as possible at mid-stream.

---

Schedule referred to in the foregoing Report.

| No. of Sample. | Time taken. | What part of River taken from. | Temperature of Sample. |
|---|---|---|---|
| | P.M. | | ° |
| 1 | 3 | Off Billingsgate, surface - - - | 56 |
| 2 | 3 | Do. 15 ft. deep - - | 56½ |
| 3 | 3.35 | Middle of Limehouse Reach, between Millwall and Commercial Docks, surface. | 58 |
| 4 | 3.35 | Do., 20 ft. deep - - | 58 |
| 5 | 4.40 | Opposite Charlton Pier, surface - - | 56½ |
| 6 | 4.40 | Do. 20 ft deep - | 56½ |
| 7 | 4.45 | Opposite North Woolwich Pier, surface | 56 |
| 8 | 4.45 | Do. 20 ft. deep | 56½ |

| No. of Sample. | Time taken. | What part of River taken from. | Temperature of Sample. |
|---|---|---|---|
| | P.M. | | ° |
| 9 | 5 | At Wreck opposite Powder Magazine, 20 ft. deep. | 56 |
| 10 | | At Wreck opposite Powder Magazine (bottom of River), 40 ft. deep. | 56 |

FURTHER SAMPLES.

On the 19th instant, accompanied by an assistant of Mr. Wigner's, I procured another sample of water and one of mud, viz. :—

| No. of Sample. | Time taken. | What part of River taken from. |
|---|---|---|
| | P.M. | |
| 18 | 3 | Water from Beckton Gas Works outlet. |
| 19 | 3.10 | Mud between the Gas Works and the Northern outfall. |

These samples, after being carefully labelled, were all taken direct to the laboratory of Mr. Wigner, who will report to you the result of the analyses.

H. O. THOMAS, Assoc. Inst., C.E.,
Surveyor to the Woolwich
22nd October 1878. Local Board of Health.

---

REPORT by G. W. WIGNER, F.C.S., upon the CONDITION of the RIVER THAMES from London Bridge to Woolwich, with special reference to the question as to whether the water was so contaminated by sewage discharge on the 3rd of September 1878 as to cause the death of any of the passengers on board the "Princess Alice," together with a TABULAR STATEMENT of results of the analyses of samples obtained at different points. Presented to the Board and ordered to be printed on the 22nd October 1878.

*To the Woolwich Local Board of Health:—*

GENTLEMEN,

IN accordance with the instructions given by the resolution of your Board on the 8th of October 1878, I have examined, both chemically and microscopically, a series of samples of water taken from the River Thames at various places, in order to ascertain whether the river is contaminated by drainage matter, and whether there is any foundation for the assertions that its foul condition had increased the number of deaths on the night of the unfortunate accident to the "Princess Alice."

Your surveyor, Mr. Thomas, and I, agreed that it was desirable I should accompany him when the samples were taken, in order to observe the condition of the river, and to take note of the temperature of the water where the samples were obtained, and any other physical conditions which might bear upon the matter of inquiry.

Accordingly, on the 14th October, in a steam launch kindly placed at our disposal by the Thames Conservancy Board, we obtained the necessary samples, and I now submit my report thereon as follows:—

As your Board are doubtless aware, reports on the state of the Thames have recently been presented to the Thames Conservancy by Captain Calver, and to the Metropolitan Board of Works by Sir J. Bazalgette and Messrs. Keates and Dupré, and it is necessary that I should refer to these reports, as they constitute part of the information which is available to enable a correct judgment to be formed of the condition of the river.

PRINCIPAL CAUSES OF VARIATION IN PURITY OF RIVER.

I must point out that in the tidal portion of the river in the vicinity of Woolwich the degree of contamination, if any, is seriously affected by at least three principal causes; and therefore, unless care is taken to procure samples under certain definite and well-known conditions, no useful information can be obtained. These three causes are—

1st. The rise and fall of the tide.

In this respect Mr. Thomas and I, in compliance with the resolution of the Board, took care that the samples from the neighbourhood of Woolwich were obtained under tidal conditions corresponding as nearly as was practicable with those which prevailed at the time of the accident to the "Princess Alice."

2nd. The flow of fresh water down the river, as shown by the amount of water flowing over Teddington Lock.

This flow is dependent upon the recent rainfall in the watershed drained by the upper reaches of the Thames. In reference to this point I find that on the day of the wreck the water at Teddington Lock stood at one foot over the mean summer level, and this had been about the average height for some days previously. On the 14th October, when my samples were taken, the water at the same place stood at eight inches over mean summer level, or only four inches less than it was on the date of the wreck; therefore, the conditions under which my samples were taken were in this respect also nearly identical with those which prevailed on the night of the wreck, and they represent rather more than the average amount of dilution of the river with the comparatively pure rainfall from the upper reaches. The conditions prevailing on the 15th January last, when the greater part of the samples reported upon by Messrs. Keates and Dupré to the Metropolitan Board were obtained, were, however, directly opposed to this.

3rd. The amount of sewage being discharged from the outfalls, which is necessarily dependent to a considerable extent on the recent rainfall in the Metropolitan district.

It is impossible for me to give an opinion whether the circumstances were in this respect the same when my samples were taken as on the night of the wreck.

STATE OF RIVER WHEN MESSRS. KEATES' AND DUPRÉ'S SAMPLES WERE TAKEN.

I must now point out to your Board that the analyses of the large number of samples taken on the 15th January, and examined by Messrs Keates and Dupré, and which are mainly relied upon by the Metropolitan Board as proofs of the pure state of the river, do not throw any light whatever on its ordinary condition at and near to Woolwich, because, as has been pointed out by Captain Calver, the river had for some month or so prior to that date been in flood, and the water level at Teddington standing from 3 feet to 5 feet 9 inches above the standard summer level. Captain Calver remarks: "The effect of this enormous discharge "was, of course, to substitute *pure for impure* water "throughout the whole length of the Thames from "Teddington to the sea."

A comparison of the results of the analyses which I now submit with those of Messrs. Keates and Dupré will show that this statement is fully borne out, as the body of comparatively pure water which was going down when their samples were taken was so enormous relatively to the ordinary or normal condition of the river, and to the size of the river basin, that the water in the centre of the river off Billingsgate on the 14th October contained as large an admixture of sea-water as Messrs. Keates and Dupré found at the same time of the tide at Erith, some 12 or 14 miles lower down the river; or, to put it in another way, the whole basin of the Thames from Teddington to Erith was on

APP. O.

the 15th January filled with water which consisted of a large proportion of pure river water which had come over Teddington Weir, and a smaller proportion of sea-water, or water which had come up the river, than was present on the 14th October at Billingsgate.

It is obvious, therefore, that the time selected by the Metropolitan Board of Works for the collection of their series of nearly 400 samples was that when the river at and near Woolwich was under the most favourable conditions possible, since the enormous scour produced by this large body of fresh and comparatively pure water had carried the impurities down to the sea.

On the other hand, Mr. Thomas and I selected a time when the conditions as regards the body of water coming down represented a fair average.

With these preliminary observations I pass to consider the following questions:—

1. Is the river contaminated with sewage?
2. If so, is the sewage contamination so great as to be injurious to Woolwich?
3. Is it probable that the condition of the river on the night of the accident was so bad that some of the drowning people were poisoned by it, or that the loss of life was increased by it in any other way?
4. If this contamination exists, is it due to the sewage from the Metropolitan outfalls?

### Is the River contaminated with Sewage?

1. In my opinion the river is contaminated with sewage, although the extent or degree of this contamination, and the amount of decomposition which has ensued, differs considerably at various points. From the tabular statement which accompanies this report it will be seen that samples were taken from the immediate neighbourhood of the northern and southern outfalls, and at seven other points, viz., off Billingsgate, Limehouse Reach, off Charlton Pier, off North Woolwich Pier, at the spot where the wreck of the "Princess Alice" was found, half way beneath the northern and southern out-falls, and at Jenning-tree Point. At each place samples were taken at the surface and about half way between the surface and the bottom of the river.

All these samples show by the chlorine present a large admixture of sea water with the fresh water coming down the river and the sewers; and the proportion of this admixture increases, as might be expected, with tolerable regularity in proceeding down the river. At Billingsgate the proportion of sea water is about 10 per cent. of the total volume. In Limehouse Reach this has more than doubled; and at the wreck the proportion is probably about 35 per cent. of sea water to 65 per cent. of fresh water. This fact is important, as sewage, when diluted with sea water, gives off more offensive effluvia than when diluted with fresh river water.

A remarkable fact is, however, to be noticed in the figures in the accompanying table, viz., that in almost every case the water at the lower part of the river contains a larger proportion—in some cases a very much larger proportion—of salt than the water at the surface. This would seem to indicate that the sea water flows upwards along the bottom of the river, leaving the land water and sewage to pass nearer to the surface. Of course, very great admixture takes place between them, but still the general rule apparently holds good. This fact may have a very important bearing upon the question of the state of the river, inasmuch as, by the heaviest water running at the bottom with the flood tide, a large number of the lighter particles of sewage deposit (especially of those particles which are of organic origin, and therefore more injurious,) may be kept from subsiding as readily as would otherwise be the case; and they may, in fact, be held up so as to be carried up stream by the incoming flood tide rather than down stream by the ebb, and may thus increase the pollution of the Upper Reaches.

The amount of combined sulphuric acid present in the samples increases with tolerable regularity as we proceed down the river, with the exception of the samples from Jenning-tree Point. This combined sulphuric acid is partly decomposed by the organic matter of the sewage, and gives rise to the liberation of sulphuretted hydrogen, which has a most offensive smell.

All the samples I obtained were turbid and offensive in appearance, but there was no very marked difference between them, with the exception of the two taken at the outfalls. All of them had a more or less offensive smell. This smell in the Billingsgate samples was slight, although readily perceived on shaking up a small quantity of the water; but it gradually increased in the other samples, till, in those taken off Woolwich Pier, it became most objectionable, and one of these gave off a sensible quantity of sulphuretted hydrogen. The samples taken at the wreck were still worse, the surface sample having a most offensive smell, and the other two samples but little less. In the samples taken midway between the outfalls in mid-stream, the characteristic smell of sewage was quite apparent, while the Jenning-tree Point samples were somewhat better.

When the sedimentary matter was allowed to subside the samples had a yellowish brown colour, and in the case of one of those from between the northern and southern outfalls this approached to a full urine yellow.

The amount of organic matter dissolved by the water, all of which must have been derived from animal or vegetable contamination, varied greatly at different points. Off Billingsgate there were only 30 to 35 grs. per gall., but the surface sample from Limehouse Reach showed 516 grs. per gall., *i.e.*, considerably more than 1 oz. per gall. of matter capable of putrefying. This proportion does not change with anything like the regularity that the mineral constituents do. Thus we find that there were 361 grs. of organic matter per gall. in the surface sample off Charlton Pier, and 154 grs. per gall. in the deep sample; while at Woolwich Pier there were 151 grs. per gall. in the surface sample, and 211 grs. per gall. in the deep sample. The surface sample from the wreck contained 140 grs. per gall., the mid-depth sample 212 grs. per gall., and the deep one 125 grs. per gall. One sample from Limehouse Reach and one from off Charlton Pier are rather worse than the worst of those taken from the wreck, but all the other samples are better than these.

Messrs. Keates and Dupré made a large number of estimations of suspended organic matter in the samples taken on January 15th, but, as the river was in flood, they of course found but little. I do not find that they made any similar determinations of dissolved organic matter.

The nitrogenous constituents, which are taken by many chemists as the main indication of sewage contamination, are somewhat lower throughout than I should have expected from the figures already quoted; but as they are fully set out in the table, I need not refer to them further than to say that they indicate very considerable contamination.

The amount of oxygen absorbed, which is a rough indication of the amount of oxidation necessary to convert these foul and offensive compounds into comparatively innocuous ones, is in nearly every case very high, most of the samples considerably exceeding half the figure found in the sample taken at the northern outfall.

The amount of suspended matter, that is, impurities which are capable of settling out of the water, is very variable. The sample taken from the wreck, at a depth of 40 feet., contained 4·9 grs. per gall. of suspended organic matter, and 27·4 grs. per gall. of suspended inorganic matter. One of the Billingsgate samples contained 16 grs. per gall., and one from Jenning-tree Point, which was the largest proportion found, 34 grs. per gall.

So far, the consideration of all the chemical results might be held to give amply sufficient proof of the presence of sewage; but, in addition, I have examined each sample microscopically, paying special attention to the characteristics of the sedimentary matter. I should point out here that animalculæ alone are not in themselves a proof of sewage contamination, but that the microscopical evidence of this has to be found mainly in the presence of fragments of cotton fibre, disintegrated paper, the skin or husk of wheat or other foods, and traces of partially digested or decomposed muscular fibre or other food.

The results of the microscopical examinations varied greatly. All the samples literally swarmed with living and dead animalculæ of various kinds. Most of those species found even as high up the river as Billingsgate corresponded with those found in the samples taken at the northern and southern outfalls. In the Billingsgate samples there was, in addition to a large number of infusoria and diatoms, unmistakable evidence of sewage contamination, inasmuch as I found in a single drop of the sediment from the water (which sediment was of a bluish black colour) one distinct piece of partially decomposed muscular fibre, a piece of the husk of wheat or one of the other cereals, several hairs, and a

considerable quantity of cotton fibre. We have here then an unmistakable proof that sewage had in some manner or other found its way to this place.

In the Limehouse Reach samples there was a very large quantity of disintegrated paper and cotton fibres, but no other structures peculiar to sewage could be recognised. In the Charlton Pier samples there were a considerable number of hairs, some evidently human and others being animal hairs. The sediment from the sample taken off North Woolwich Pier was of a much lighter and more flocculent character. It contained a very large amount of decaying vegetable tissue, but, with the exception of the dead animalculæ with which swarmed, no animal remains could be detected.

The samples taken from the scene of the wreck were unquestionably worse than the last referred to. In the sedimentary matter I found cotton fibre, fragments of muscular fibre, many fragments of paper, a fragment of husk of wheat, and some hairs.

I pass over the samples from the two outfalls, simply stating that, as was to be expected, they contained the most abundant evidence of decomposing sewage matter.

The samples taken midway between the two outfalls closely resembled those taken at the wreck, and the evidence of sewage contamination was unmistakable, while the samples from Jenning-tree Point showed a very large amount of disintegrated vegetable tissue and particles of cotton fibre.

I think the various facts detailed above in reference to the individual samples afford the most conclusive ground on which to base an opinion—that the whole of the river from Billingsgate to Jenning-tree Point was, on the 14th October last, greatly contaminated with sewage, and that, subject to certain irregularities which may be due to local circumstances in the river, this contamination increased as we passed down it, and that on the whole the greatest contamination was found in the samples taken at the wreck, and half-way between the two outfalls.

### Is the Sewage Contamination so great as to be injurious to Woolwich?

2. This question is unfortunately to a large extent a matter of opinion; but if the state of the river on the 14th October represents, as I have reason to believe it fairly does, its average state at Woolwich, my own opinion is that unquestionably the effluvia given off from the sewage contaminated water is sufficiently great to be injurious to health.

### Did the Condition of the River on September 3rd increase the Loss of Life?

3. In reply to this question, I do not think that, as far as can be judged from the samples I have examined, it would be right to say that any of the unfortunate passengers in the "Princess Alice" were absolutely poisoned by the water; but it does seem to me extremely probable that the intolerably nauseous smell, accompanied as it doubtless is by an equally nauseous taste, may have produced sudden vomiting in some of the persons in the water, and that by this means what little strength or power they had to save themselves by swimming may have been lost, or, as in the mere act of vomiting, the lungs may have been emptied of air and refilled with water; the body would thus become specifically heavier than water, and people may have sunk who might otherwise have been saved, had the water been in good and clean condition. While, therefore, I think it quite possible that some loss of life may be indirectly attributed to the foul condition of the river, I do not think it was sufficiently foul for the small quantity which could be imbibed to actually poison anyone. I cannot, however, omit to mention that I think the small quantity swallowed may have materially complicated the after symptoms in the case of some of the survivors.

### Is the Contamination caused by the Sewage from the Metropolitan Outfalls?

4. The question as to the cause of the contamination seems to me to be answered more readily by looking at it from an engineering point of view rather than from a chemical one. The chemical and microscopical analyses show contamination with actual sewage matter as far up as Billingsgate. It is obvious, therefore, that it would be useless to look in Woolwich Reach itself for any specific evidence of contamination which could be considered as coming solely from the North Woolwich outfall, because, having once shown that sewage matter does work up stream a distance of some miles, we are bound to admit the possibility of the sewage matter from the northern outfall working up so as to cause contamination or deposits in Woolwich Reach; but, taking the relative sizes and populations of the districts drained by the North Woolwich sewer and by the Barking and Crossness outfalls together, I think it will be found that the population whose sewage passes through the North Woolwich outfall is not more than about one thousandth of the population whose sewage passes from Barking and Crossness. Assuming, therefore, that all passed into the river at the same point, it would be perfectly legitimate to contend that $\frac{999}{1000}$ of the contamination was due to the larger outfalls, and only one thousandth to the North Woolwich outfall; and it appears to me that the slight difference in position of the outfalls does not sensibly affect this argument.

### Additional Report on Samples from Beckton Gasworks Outfall.

On the 19th October instant I received from Mr. Thomas two more samples, one of which was water taken from the outfall of the Beckton Gasworks, and the other was a sample of mud taken from the foreshore between the gasworks and northern outfall.

The water from the gasworks outfall was simply an admixture of sewage and salt water. The microscope showed the presence of muscular tissue, cotton filaments in large quantity, many hairs both animal and vegetable, and fragments of cooked farinaceous food. This outfall is, therefore, clearly a source of contamination.

The sample of mud from the foreshore between the gasworks and the northern outfall gave the following results on the dried mud:—

| | |
|---|---|
| Organic matter | 15·5 per cent. |
| Mineral matter | 84·5 ,, |
| | 100·0 |

The microscope showed that the organic matter was derived from sewage, since it contained animal and vegetable hairs, and pieces of muscular fibre. The sample had an offensive smell, and effervesced strongly with acids, giving off a strong smell of sulphuretted hydrogen.

We have therefore one proof that, as regards this particular part of the river, the sewage matter does deposit on the bank.

I am, &c.,
G. W. Wigner, F.C.S.

# APPENDIX P.

EXTRACTS FROM REPORTS TO THE COURT OF COMMON COUNCIL OF THE CITY OF LONDON FROM THE PORT SANITARY COMMITTEE.

## THAMES OUTFALLS.

REPORT to the COURT OF COMMON COUNCIL, from the PORT SANITARY COMMITTEE, presented 15th December 1881.

Ellis, Mayor.

A Common Council holden in the Chamber of the Guildhall of the City of London, on Thursday, the 15th day of December, 1881.

The Port of London Sanitary Committee did this day deliver into this Court a Report in writing under their hands, on the reference of the 6th October 1881 to inquire into the sanitary condition of the River Thames in the neighbourhood of Crossness and other outfalls, and to report what steps should be taken to remedy any existing evils thereat, with authority to confer with Her Majesty's Government thereon, and recommending that application be made to the Home Secretary to take action under the provisions of the 21st and 22nd Vict. cap. 104. sect. 31, which was read.

Resolved, that the consideration thereof be adjourned, and it is ordered that the Report be printed, and a copy sent to every member of this Court.

MONCKTON.

To the Right Honourable the Lord Mayor, Aldermen, and Commons of the City of London in Common Council assembled.

WE whose names are hereunto subscribed, of your Port of London Sanitary Committee, to whom on the sixth day of October 1881 it was referred to inquire into the sanitary condition of the River Thames in the neighbourhood of Crossness and other outfalls, and to report what steps should be taken to remedy any existing evils thereat, with authority to confer with Her Majesty's Government thereon, do certify that we have duly proceeded therein, and appointed a Sub-committee, consisting of 18 members of your Committee, to proceed down the river, and themselves take samples of the water at the points referred to in the reference, viz., at Crossness and other outfalls.

Our Sub-committee have since reported to us that on the 23rd November and the 3rd December they proceeded to the points in question, inspecting on the former date and taking samples of the lower part of the river, viz., from Gravesend to Woolwich, and on the latter date of the upper part, viz., high as Teddington Lock. They then instructed our medical officer of health, Dr. Collingridge, to make analyses of the water obtained by them, and report fully thereon.

By direction of your Committee they also instructed Dr. Collingridge to engage the services of Professor Wanklyn, to make independent analyses of the water in question.

The respective analyses of these gentlemen have been made, and reports thereon laid before and carefully considered by your Committee, and are appended hereto for the information of your Honourable Court.

In the minds of your Committee there can be no doubt that the action of the Metropolitan Board of Works under the Metropolis Local Management Act, in taking the sewage of the metropolis down the river to Crossness and Barking Creek, has materially benefited that part of the Thames immediately adjacent to London; but equally without doubt the state of the river at these points, although, being greatly affected by constant meteorological changes, it must of necessity vary from time to time, is, in consequence of the great outpouring of sewage, always in a condition most unsanitary, and that in hot weather in times of drought and great heat its very prejudicial effect upon the public health is obvious, and bearing in mind the fact that the quantity of sewage has of late years enormously increased, and is constantly increasing, your Committee feel that the time has arrived when some definite action should be taken in the matter, and therefore after full consideration deem it expedient that the Corporation should avail itself of the step which, by the Metropolis Local Management Act, 1858, cap. 104, sect. 31, appears open for it to adopt.

This section is as follows, viz.: "It shall be lawful "for one of Her Majesty's Principal Secretaries of "State, at his discretion, on representation or com- "plaint made to him of any nuisance committed in "or execution of any works, or in deodorizing any "sewage, or disposing of any sewage or refuse from "sewers, or in any other manner under this Act, to "cause inquiry to be made into the matter represented "or complained of to him, and to direct such prose- "cutions or to take such other proceedings as he may "think fit, in order to insure the prevention or abate- "ment of such nuisance as aforesaid;" and we accordingly recommend that we should be authorised to apply to the Secretary of State, with the view, under this section of the Act, of remedying the evils complained of.

Your Committee would here add that as the Metropolitan Board of Works are about to extend the sum of 160,000*l.* in enlarging the outfalls works both at Crossness and Barking, the recommendation of your Committee should in our opinion be adopted by your Honourable Court and carried into effect at as early a date as possible.

All which we submit to the judgment of this Honourable Court.

Dated this 14th day of December 1881.

*(Here follows a Report from Dr. Collingridge, dated 8th December* 1881, *for which see his evidence.)*

EXTRACTS from a subsequent REPORT of the PORT OF LONDON SANITARY COMMITTEE, 16th March 1882.

To the Right Honourable the Lord Mayor, Aldermen, and Commons of the City of London, in Common Council assembled.

WE whose names are hereunto subscribed of your Port of London Sanitary Committee, to whom it was referred to carry into execution the Public Health Acts, 1872 and 1875, beg to submit for your consideration the Half-yearly Report of William Collingridge, Esq., M.B., the medical officer of health of the port of London, for the half-year ending the 31st December 1881, which report contains a full and detailed statement of the work done during that period in the port of London by the medical officer and the inspectors.

The report also calls attention to the condition of the water in the river, which must, whilst the sewage of the metropolis is passed into the river, be a source of great anxiety to all concerned in the health of those engaged thereon.

The special report of the medical officer of health on this subject, appended to our report, agreed to by your Honourable Court on the 19th January last, is annexed to the report of Dr. Collingridge now presented, and your Committee would here state that, under the reference from your Honourable Court of the 19th January last, to carry into execution our report upon the "Thames Outfalls," energetic measures are being taken with a view to alleviate the existing evils in this respect.

*(Here follows Report of Dr. Collingridge, dated 4th January* 1882, *for which see his evidence.)*

## APPENDIX Q.

MEMORIAL FROM THE VESTRY OF PLUMSTEAD.

To the Right Honourable BARON BRAMWELL and others Her Majesty's Commissioners. Upon the subject of the Pollution of the River Thames.

THE MEMORIAL OF THE VESTRY OF PLUMSTEAD, IN THE COUNTY OF KENT,

SHOWETH,

"1. That by the Metropolis Local Management Act, 1855, sec. 135, the Metropolitan Board of Works were directed to prevent the sewage of London from flowing into the River Thames in or near the Metropolis.

"2. That the said Board has constructed huge outfalls at Barking and Crossness, whereby the sewage in immense quantities is discharged into the river, both in and near the Metropolis, to the great detriment of the public health, and in entire contravention of the said Act.

"3. Long before 1855, and ever since, it was never contemplated by the Legislature that the said Board would so flagrantly act in violation of their public duty, or that the said sewage would be dealt with in any other way than by a very distant removal of it from the Metropolis.

"4. In 1865 a Select Committee of the House of Commons took exhaustive evidence upon the subject, and in that and the following years two Acts were passed for the purpose of enabling the sewage at Barking to be carried right out to the Maplin Sands; and your memorialists respectfully urge that the Royal Commission should read that evidence and those Acts, and investigate the reasons why the salutary recommendations of the House of Commons contained therein were not carried out; and they earnestly request that you should examine Colonel Hope and the Secretary of the Stock Exchange upon the subject, and make them produce all the papers they have in relation thereto.

"5. So far as your memorialists have been able to ascertain, no good reason has ever been given why such recommendations have not been carried out.

"6. Some years ago the Native Guano Company spent upwards of 30,000*l.* in creating a clear effluent out of the sewage at Crossness, but your memorialists are informed that the said Board caused the Company's works to be suddenly stopped and blown up with gunpowder, and no good reason has ever been given for this extraordinary conduct, and your memorialists consider that this ought to be made a subject of close inquiry by the Royal Commission, and your memorialists hope that the officers of the Company and of the Board will be examined upon the whole question.

"7. It is not improbable that by a combination of the recommendations of Parliament in 1865, with some such system as that tried at Crossness, the river could be successfully saved from the pollution which is at present created.

"8. In 1878 nearly 800 persons were drowned in the river within the parish of Plumstead, and much of the evidence on the coroner's inquest went to show that many of them were poisoned or suffocated by the foul sewage in the river.

"9. Mr. Carttar, the coroner for this district, can give important evidence as to the number of deaths that have since arisen from this cause.

"10. The parochial medical officers' report shows fever to be very prevalent in the parish, and at low tide the mud of the river shore is infested with living organisms visible to the naked eye.

"11. Mr. T. N. Moors and Mr. George Webb, members of the vestry of Plumstead, and residents in the parish, can also give some evidence as to the foulness of the river, and its effects.

"12. Mr. Mellniss, a civil engineer, of Gresham House, in the city of London, has informed your memorialists that he has given great study to the question, and is in a position to give useful evidence to the Committee thereon.

"13. Your memorialists consider that some economical and efficient means ought to be adopted for speedily ridding the river of the sewage, and turning it into a profitable manure for the land.

"Your memorialists therefore respectfully and earnestly beg that the above-mentioned persons may be heard and examined by you before you report upon the subject of the Pollution of the River Thames to her Majesty."

J. MCALLISTER,
3rd November 1882. Chairman.

App. R.

## APPENDIX R.

REPORT on the OBSERVATIONS made in the RIVER THAMES for the CORPORATION of the CITY of LONDON, acting as the PORT of LONDON SANITARY AUTHORITY, in reference to the DISCHARGE of SEWAGE from the METROPOLITAN OUTFALLS. By BALDWIN LATHAM, M. Inst. C.E., F.G.S., F.M.S., 7, Westminster Chambers, Westminster, S.W., January 1883.

(*Put in by Mr. Latham, 23rd January* 1883.)

IN the investigations made to ascertain the influence of the discharge of sewage at Barking, Crossness, and other places, into the tidal channel of the River Thames, it has been deemed advisable to prepare a careful survey of the river, and to make a number of sections in order to ascertain its tidal capacity, and the relative sectional area at every portion of its course at mean tide level. This part of the work has been entrusted to Mr. James Mansergh, M. Inst. C.E., and Mr. Chas. J. More, M. Inst. C. E.

In order to accurately determine the range of oscillation about the point of the Northern Outfall at Barking, a series of float observations have been undertaken, and to ascertain the vertical range of the tides, self-recording tide gauges have been erected, or the observations from those already in existence have been procured, so as to obtain a complete knowledge of the tidal phenomena in the river.

During the whole of the period that the tidal observations have been going on, a series of actual gaugings of the streams of water flowing into the tidal portion of the river below Teddington Lock have been made at the following places:—

The River Thames at Teddington.
Stream entering the Thames at Strawberry Hill.
Stream passing through Twickenham.
The River Crane at Isleworth.
The River Brent and Grand Junction Canal.
A stream entering at Chiswick called the "Duke's Ditch."
The Beverley Brook.
The River Wandle.
The Regent's Canal and Limehouse Cut.
The River Ravensbourne.
The River Lea.
The River Roding and its branches.
Mayes Brook and its tributaries.
A stream entering at Horse Shoe Corner.
The River Beam and stream between Rivers Beam and Ingreborne.

River Ingreborne.
Stream entering at Erith Reach, and streams at Wennington.
Mar Dyke.
The River Cray and its tributary.
The River Darent.
The Grays Chalk Quarries.
Streams at Northfleet, Chadwell St. Mary, and Tilbury.
Streams at Gravesend Reach, Higham, Mucking Creek, and Higham Creek.
Streams at Stanford-le-Hope and north of Stanford-le-Hope.
Streams at Fobbing and north of Fobbing.
Vange Wharf and Stream.
Stream at Pitsea Creek.
Streams at Cooling.
Wall End, Barking.

In the whole, actual gaugings have been taken at 50 stations, and the area not gauged, including the area of the river and part of the metropolis, is 284 square miles, from which an estimated amount of surface and spring water has been calculated as finding its way into the river during the course of these experiments. The area calculated in this way forms but the $\frac{1}{18}$th part of the whole catchment basin of the Thames. The volume of water-supply, taken from Colonel Bolton's returns, is also added, as all this water naturally belongs to the Thames Basin, and after use is again returned to the river.

---

### Tidal Experiments.

A series of float experiments were undertaken in order to accurately ascertain the tidal range in the River Thames, or the distance at various periods at which matters floating in the river would pass backwards and forwards with the ebbing and flowing tide.

The floats used in these experiments, numbered 1 to 8, were of a massive character, being 12 feet 6 inches in length, weighted at the bottom end so as to swim in a vertical position, and constructed of solid timber 11½ inches in diameter, and were immersed 12 feet in the water. The floats were of an octagonal form so as to offer at every position nearly the same surface of exposure to the action of the current in the river.

Seven distinct sets of observations were made with these floats on the range of the tides. The floats were put into the river at various periods of tidal flow, for example, the first three floats were placed in the river on the 14th September 1882, being the period of spring tide, No. 1 float being placed in at high water, No. 2 float three hours after high water, and No. 3 float at low water. Nos. 4, 5, and 6 floats were placed in the river on the 22nd September, being the period of neap tide, No. 4 float being placed in at high water, No. 5 float three hours after high water, and No. 6 at low water. It being found on the 5th October that Nos. 3 and 5 floats were in close proximity to each other, No. 5 float was taken out of the river and re-started as No. 7 float, being placed in the river at half flood tide on the 6th October at the period of neap tide.

The eighth experiment was made with a float 4 feet deep, 11½ inches diameter, weighted at the bottom and floating 4 inches out of the water. It was started in the river below Teddington Weir, in the afternoon of the 27th October, and was allowed to take its course down the river.

The ninth experiment consisted in making simultaneous observations in the river in different parts with floats of a similar character to those used in the observations No. 1 to 7, for which purpose the floats were put in the river at high water, and were allowed to flow down and up with the current.

In the tenth experiment two sets of floats were used, or surface floats and deep floats. The surface floats were constructed of a wooden ball 1 foot diameter, and were used to test the relative rate of velocity between them and the deeper floats. Another important object of this experiment was to ascertain, by means of samples of water, what degree of admixture of the upland and sea-water took place in the river during the ebb and flow of the tide.

The floats Nos. 1 to 7 were watched night and day by two men in a rowing boat, and the boats were under constant inspection by the observers in the steam-tug "Toby," which had been specially retained for the purpose. The float observations were carried out under my instruction, and were from time to time inspected by me; but in order to ensure the greatest accuracy they were placed under the personal care of Mr. R. W. Peregrine Birch, M. Inst. C.E., who took up his quarters, during the period of observation, on board the steam-tug.

Although the experiments were started at high water at spring tide on the 14th September 1882, owing to a fog on the night of that day, and the men not being thoroughly conversant with the work, the first start proved abortive, and it was not until the 17th September that the experiments fairly commenced.

The following particulars will show the various points of importance with reference to the movement of the floats in the river.

#### *No. 1 Float.*

No. 1 float was put into the centre of the River Thames at high water, opposite the Metropolitan Northern Outfall Sewer at Barking, at 4h. 25m. P.M. on the 17th September 1882. The tides at this period were "taking off," high spring tide having occurred on the 14th September. On the ebb tide the float descended as far as Denton Wharf, 15·84 miles below the point at which it was put in. On the returning tide, on the morning of the 18th September, the float reascended the river to a point in Halfway Reach 2·77 miles below the Northern Outfall Sewer, and in the afternoon of the same day, at high water, it reached a point 2·14 miles below the Northern Outfall Sewer, and so the float progressed backwards and forwards in the river, until at low water at noon on the 20th September it reached a point in Gravesend Reach 16·73 miles below where it was inserted, being about a quarter of a mile above Shorne Mead Battery. On the afternoon of the 22nd September, being the period of neap tide, the float at high water was at a point in Long Reach 7·65 miles below the Northern Outfall Sewer, and at low water on the morning of the 23rd September it was near Coal House Point, 17·56 miles below the Northern Outfall Sewer. On the morning of the 24th September, at low water, the float had reached a point 18·32 miles below the Northern Outfall Sewer, and at high water on the night of the 24th September it was in Erith Reach, 3·92 miles below the Northern Outfall Sewer. Early in the morning of the 27th September, at high water, the float had ascended the river to a point 0·65 of a mile above the Northern Outfall Sewer, and on the following low water it had reached a point in Gravesend Reach 13·37 miles below the Northern Outfall Sewer. On the morning of the 29th September, being the period of high spring tide, the float had reached a point in Woolwich Reach, 2·08 miles above the Northern Outfall Sewer, and at low water on the following tide it had descended to a point in the lower part of Northfleet Hope, 13·10 miles below the Northern Outfall Sewer. On the morning of the 1st October, at high water, the float was 0·05 of a mile below the Northern Outfall Sewer, and at low water on the morning tide of the same day it had reached a point in Gravesend Reach 15·38 miles below the Northern Outfall Sewer. On the morning of the 4th October, at high water the float was in Long Reach, 7·13 miles below the Northern Outfall Sewer, and at low water on the same day it was in Gravesend Reach, 17·36 miles below the Northern Outfall Sewer. On the afternoon of the 6th October, being the period of neap tide, at high water the float was off the Leather Bottle, 1·66 miles below the Northern Outfall Sewer, and at low water in the morning of the 7th October it was in Northfleet Hope, 13·00 miles below the Northern Outfall Sewer. At high water on the morning of the 12th October the float was off the Leather Bottle, 1·62 miles below the Northern Outfall Sewer, and at low water on the same morning it was at a point off Rosherville, 13·87 miles below the Northern Outfall Sewer. On the 13th October, at high water on the morning tide, the float was in Halfway Reach 1·76 miles below the Northern Outfall Sewer, and about two hours after the return of the float down the river a fog came on, and the float was lost. At noon the same day it was again started in a position with reference to No. 4 float, which had been continuously working during the period, similar to that which it had occupied on the previous tide, and in the afternoon, on the first tide, after being so started, it had reached a point at high water in Halfway Reach, 2·22 miles below the Northern Outfall Sewer, and at low water in the afternoon of the same day it had reached a point in Gravesend Reach, 17·50 miles below the Northern

App. R.

Outfall Sewer. On the morning of the 14th October, being the period of high water spring tide, at high water the float was in Halfway Reach, 2·20 miles below the Northern Outfall Sewer. On the morning of the 16th October, at high water, the float was 2·00 miles below the Northern Outfall Sewer, being opposite the Metropolitan Southern Outfall Sewer at Crossness, and at low water on the same morning it was in Gravesend Reach, 13·63 miles below the Northern Outfall Sewer. On the succeeding flood tide the float made considerable progress up the river, so that at high water on the afternoon tide it was in Woolwich Reach, 2·00 miles above the Northern Outfall Sewer, and on the high-water morning tide of the 17th October the float had reached a point in Greenwich Reach 6·56 miles above the Northern Outfall Sewer, and at low water had descended to a point in Long Reach 6·62 miles below the Northern Outfall Sewer. At high water on the succeeding tide the float descended somewhat lower, being in Blackwall Reach, 5·52 miles above the Northern Outfall Sewer, after which it gradually descended, so that at high water on the morning of the 19th October it was in Woolwich Reach, 2·75 miles above the Northern Outfall Sewer. On the morning tide of the 21st October, being the period of neap tide, at high water the float had descended to a point in Barking Reach, 1·13 miles below the Northern Outfall Sewer, and at low water in the afternoon of the same day it had reached a point in Fiddler's Reach 10·20 miles below the Northern Outfall Sewer. On the morning of the 22nd October, at high water, the float had reached a point in Halfway Reach 1·56 miles below the Northern Outfall Sewer, and in the afternoon of the same day, at low water, it was in Northfleet Hope, 11·60 miles below the Northern Outfall Sewer. At high water on the morning of the 24th October the float was in Halfway Reach, 2·15 miles below the Northern Outfall Sewer. Shortly after high water a gale came on, rending it impossible to observe the floats in this part of the river, so that the experiment was discontinued until the afternoon of the 25th October, when the float was again put into the river at low water, in exactly the same position as it had occupied at low water on the morning tide of the 24th October. At high water on the early morning of the 26th October the float had reached a point in Woolwich Reach, 2·00 miles above the Northern Outfall Sewer, after which it was again lost in a fog, and to continue the experiment, the float was again put into the river at high water on the afternoon tide of the same day, and at the same spot at which it had reached at high water on that morning previous to its being lost in the fog. It descended the river on the ebb tide to a point in Northfleet Hope, 12·08 miles below the Northern Outfall Sewer, and on the succeeding flood tide reascended the river to a point in Blackwall Reach 5·22 miles above the Northern Outfall Sewer. On the morning of the 28th October, being the period of spring tide, the float at high water had reached a point in Greenwich Reach, 7·23 miles above the Northern Outfall Sewer. In the evening of the same day a gale came on, and the experiment was discontinued until the afternoon of the 29th October, when the float was again put into the river, at a point 0·42 of a mile below the position which it occupied at high water in the afternoon of the 28th October. On the ebb tide it descended to a point in Fiddler's Reach 10·55 miles below the Northern Outfall Sewer, and reascended on the flood tide to a point in Woolwich Reach, 2·10 miles above the Northern Outfall Sewer. On the morning of the 1st November the float had reached a point in Halfway Reach 2·20 miles below the Northern Outfall Sewer, and at low water the same morning it was at a point in Gravesend Reach, 17·45 miles below the Northern Outfall Sewer. The float again ascended the river, but a heavy gale having arisen, the experiment was stopped.

It will be observed that, in the forty-five days this float had been in the river, it only made a progress of 2·20 miles down it, that is upon the assumption when there was a break in the experiment, the float was reinserted in its proper position with reference to the former experiment, but it will be seen from the diagrams that these corrections are rather favourable than otherwise to the descent of the float down the river. In two complete lunations, or to the morning of the 16th October, the float had descended 2·00 miles down the river. It will also be observed that in the twenty-six days in which there was no break in the experiments, that is, between the 17th September and the 13th October, the float had only progressed down the river 1·76 miles from the point at which it was inserted opposite the Northern Outfall Sewer.

*No. 2 Float.*

No. 2 float was put into the centre of the river, opposite the Northern Outfall Sewer at Barking, at 7h. 25m. P.M. on the 17th September 1882, being three hours after high water. On the ebbing tide it descended to a point below Purfleet Wharf, being 7·40 miles below the Northern Outfall Sewer. On the next flood tide, on the morning of the 18th September, it ascended the river to a point opposite Greenwich Station, being 6·75 miles above the Northern Outfall Sewer. On the morning tide of the 20th September, at high water, the float was 1·95 miles above the Northern Outfall Sewer, and at low water at noon the same day it was 7·85 miles below the Northern Outfall Sewer. Subsequently the float progressed backwards and forwards, so that at high water on the morning of the 22nd September, being the period of neap tide, it was 3·10 miles above the Northern Outfall Sewer, and at low water in the afternoon of the same day it was 6·82 miles below the Northern Outfall Sewer. On the morning tide of the 23rd September, at high water, the float was but 0·30 of a mile above the Northern Outfall Sewer, and at low water on the same day it was 10·18 miles below the Northern Outfall Sewer. On the morning of the 24th September, at low water, it was 10·15 miles below the Northern Outfall Sewer, and at high water the same day it was exactly opposite the point at which it was put in on the 17th instant, or at the Northern Outfall Sewer. At high water in the afternoon tide of the 27th September the float had reached a point 5·82 miles above the Northern Outfall Sewer, and at low water in the afternoon of the same day it was 10·58 miles below the Northern Outfall Sewer. On the morning of the 29th September, being the period of high water spring tide, the float had reached a point opposite Greenwich Hospital, or 6·64 miles above the Northern Outfall Sewer, and at low water in the morning of the same day it was 6·60 miles below the Northern Outfall Sewer. At high water in the afternoon of the 30th September, the float had reached a point 9·90 miles above the Northern Outfall Sewer, being just below the point of crossing of the Thames Tunnel, and at low water in the night of the same day it had reached a point 7·10 miles below the Northern Outfall Sewer, being opposite Purfleet Wharf. On the morning of the 1st October, at high water, the float was 8·92 miles above the Northern Outfall Sewer, being in the upper portion of Limehouse Reach, and at low water on the morning of the same day it was 6·18 miles below the Northern Outfall Sewer. At high water in the afternoon tide of the same day the float had reached a point 9·70 miles above the Northern Outfall Sewer, and on the following low water descended to a point 5·60 miles below the Northern Outfall Sewer. On the morning of the 4th October, at high water, the float was 1 mile above the Northern Outfall Sewer, and just after noon on the same day, at low water, it was in the lower part of Long Reach, or 9·28 miles below the Northern Outfall Sewer. In the afternoon of the 6th October, being the period of neap tide, at high water the float was 4 miles above the Northern Outfall Sewer, and on the succeeding low water, on the morning of the 7th October, it was 6·15 miles below the Northern Outfall Sewer. On the early morning of the 10th October the float had reached a point at high water 4·40 miles above the Northern Outfall Sewer, and when descending upon the morning tide of that day it was lost sight of in the fog, and was found again near Erith Pier upon the ascending tide. The float was seen at 7 A.M., at low water, opposite the West Kent Outfall, so that there is every probability that it ran its full course. On the succeeding high water of the same day the float had reached a point above Bow Creek, or 5 miles above the Northern Outfall Sewer, and at low water on the following tide reached a point 7·80 miles below the Northern Outfall Sewer, being rather lower than the position of the West Kent Outfall into the Thames. At high water on the morning of the 12th October the float had reached a point in Greenwich Reach, 7·15 miles above the Northern Outfall, and at the following low water, in the morning of the same day, it had reached a point 7·14 miles below the Northern Outfall Sewer, being a little below Purfleet Wharf. On the morning of the 14th October, being the period of high water spring tide, the float was 6 miles above the Northern Outfall Sewer, and at low water on the following tide was 8·90 miles below the

Northern Outfall Sewer. On the morning of the 16th October, at high water, the float was 6·62 miles above the Northern Outfall Sewer, and at the following low water it was 6·15 miles below the Northern Outfall Sewer. At high water in the afternoon of the same day it had ascended the river to a point 8·08 miles above the Northern Outfall Sewer, or to Limehouse Reach, just above Millwall Docks. On the afternoon of the 17th October the float had reached, at high water, a point in Limehouse Reach, 8·25 miles above the Northern Outfall Sewer. At low water on the morning of the 18th October the float had descended to a point at Crayford-Ness, 6·10 miles below the Northern Outfall Sewer, and on the succeeding high water, in the afternoon of the same day, it had ascended to Blackwall Reach, at a point 5·45 miles above the Northern Outfall Sewer. The float again descended the river, but some time afterwards a fog came on and the float was lost.

It will be observed that, calculating from the high water of the tide following that on which the float was inserted in the river, in thirty-one days the observations were going on, the float advanced 1·30 miles down the river in the high water periods, or from 6.75 miles above the Northern Outfall Sewer to 5·45 miles above it. At the end of the two periods of lunation, ending on the 16th October, the float had ascended 1·33 miles up the river.

*No. 3 Float.*

No. 3 float was put into the centre of the river opposite the Northern Outfall Sewer, at low water, at 11h. 40m. P.M. on the night of the 17th September 1882. On the ascending tide at high water, on the morning of the 18th September, it had reached Lambeth Bridge, being 13·90 miles above the point at which it was put in the river. At low water, on the following tide, it had reached a point 0·75 of a mile above the Northern Outfall Sewer. At high water, in the afternoon of the 20th September, the float had reached Chelsea Bridge, being 16·62 miles above the Northern Outfall Sewer, and at low water on the following tide, in the early morning of the 21st September, it had reached a point 5·30 miles above the Northern Outfall Sewer. In the afternoon of the 22nd September, being the period of neap tide, the float at high water was above Vauxhall Bridge, or 14·65 miles above the Northern Outfall Sewer, and at low water on the succeeding tide, in the morning of the 23rd September, it was 3·90 miles above the Northern Outfall Sewer. At low water, on the afternoon of the 23rd September, it had reached a point 2·95 miles above the Northern Outfall Sewer. On the morning of the 24th September, at low water, the float was 2·95 miles above the Northern Outfall Sewer, being opposite the Upper Ferry at Woolwich, and at high water, on the succeeding tide, it was at Westminster Bridge, or 13·37 miles above the Northern Outfall Sewer. On the early morning of the 26th September, at high water, the float was below Chelsea Bridge or 16·50 miles above the Northern Outfall Sewer, and at low water, in the morning of the same day, it was 2·95 miles above the Northern Outfall Sewer. On the early morning of the 27th September, the float had reached a point 18·55 miles above the Northern Outfall Sewer, and at low water, in the morning of the same day, it was 4·70 miles above the Northern Outfall Sewer. On the morning tide of the 29th September, being the period of high spring tide, the float had reached a point 21·68 miles above the Northern Outfall Sewer, being opposite Messrs. Thorneycroft's works at Chiswick. At the following low water, in the morning of the same day, the float was in Greenwich Reach, or 6·62 miles above the Northern Outfall Sewer. In the afternoon of the 1st October, the float at high water was 19·20 miles above the Northern Outfall Sewer, being above Putney Bridge, and at low water on the succeeding tide had reached a point 4·70 miles above the Northern Outfall Sewer. On the morning tide of the 4th October, at high water, the float was 15·45 miles above the Northern Outfall Sewer, and on the succeeding low water of the same day it was 3·82 miles above the Northern Outfall Sewer. In the afternoon of the 6th October, being the period of neap tide, at high water, the float was 15·40 miles above the Northern Outfall Sewer, and on the succeeding low water, in the morning of the 7th October, it was 4·88 miles above the Northern Outfall Sewer. On the afternoon tide of the 12th October, at high water, the float was 19·90 miles above the Northern Outfall Sewer; and on the succeeding low water, on the same night, it was 5·75 miles above the Northern Outfall Sewer. On the next tide, in the morning of the 13th October, at high water, the float was 20 miles above the Northern Outfall Sewer. At low water, in the morning of the same day, the float was in Blackwall Reach, 6·10 miles above the Northern Outfall Sewer. At high water, on the morning of the 14th October, being the period of high water spring tide, the float was 20·15 miles above the Northern Outfall Sewer. On the morning of the 16th October, the float was 17·52 miles above the Northern Outfall Sewer or below Fulham Bridge, and at low water, in the morning of the same day, it was in Bugsby's Reach, or 4·64 miles above the Northern Outfall Sewer. At high water, in the morning of the 17th October, the float was 17·60 miles above the Northern Outfall Sewer, and at low water it was 4·70 miles above the Northern Outfall Sewer. On the following high water, in the afternoon of the 17th October, the float was 15·90 miles above the Northern Outfall Sewer, after which period it continued to descend until, in the afternoon of the 18th October, it reached a point at high water 12·85 miles above the Northern Outfall Sewer. After returning down the river some distance a fog came on, and the float was lost sight of. It was, however, again started on low water in the afternoon of the 19th October, in the same position with reference to No. 7 float (which had not been lost), and which was the nearest float to it, as it had occupied previous to its being lost. At high water, on the afternoon of the 19th October, the float had reached a point 11·00 miles above the Northern Outfall Sewer, being 1·85 miles lower than the high water of the tide preceding that upon which it was lost in the fog. At high water on the morning of the 21st October, being the period of neap tide, the float was 8·00 miles above the Northern Outfall Sewer, and at low water, on the succeeding tide it descended to a point 3·20 miles below the Northern Outfall Sewer. At high water, on the morning of the 22nd October, the float was 6·73 miles above the Northern Outfall Sewer, and at low water, in the afternoon of the same day, it was 3·38 miles below the Northern Outfall Sewer. At low water, on the morning of the 24th October, the float was 6·20 miles below the Northern Outfall Sewer. At 11h. 40m. A.M. at high water, on the same day, the float had reached a point in Greenwich Reach, 6·60 miles above the Northern Outfall Sewer. A gale coming on, the observation was discontinued until high water on the afternoon tide of the 26th October, when the float was put into the river in exactly the same position as it had occupied at high water on the 24th October. The float descended the river on the ebb tide to a point 6·19 miles below the Northern Outfall Sewer, and on the following flood tide, on the early morning of the 27th October, it passed up the river to a point 10·48 miles above the Northern Outfall Sewer. On the morning of the 28th October, being the period of spring tide, at high water the float had reached the Upper Pool, or 10·40 miles above the Northern Outfall Sewer, and at low water, in the morning of the same day, it reached a point 4·45 miles below the Northern Outfall Sewer, being just opposite Erith Church. At high water, in the afternoon of the 29th October, the float was 4·93 miles above the Northern Outfall Sewer, and at low water, on the night of the same day, it reached a point 6·80 miles below the Northern Outfall Sewer. On the morning of the 1st November, at high water, the float had descended to a point 0·30 of a mile below the Northern Outfall Sewer, and at low water on the succeeding tide it reached a point 13·80 miles below the Northern Outfall Sewer. On the following flood tide it ascended the river to a point 2·75 miles below the Northern Outfall Sewer. A gale coming on the experiment was discontinued.

It will be observed that in the forty-three days that this float was in the water, it made a progress from low water to low water of 13·80 miles down the river. It will also be observed that, if we take the thirty-one days in which this float was going backwards and forwards in the river without any interference, at the end of the period it had made no advance down the river, but ascended one mile above the point at which it was inserted. It will also be seen that in the two lunations ending the 16th October, the float had not descended at low water, but had advanced up the river 4·64 miles, and it was not until a large quantity of land water came down the river that the float made any progress seawards.

App. R.

*No. 4 Float.*

No. 4 float was put into the centre of the river opposite the Northern Outfall, at high water, at 7h. 50m. A.M. on the morning of the 22nd September, being the period of neap tide. On the first ebb it descended a distance of 6·95 miles, and on the succeeding flood, on the afternoon of the same day, it reached a point 1·70 miles above the Northern Outfall Sewer. On the morning of the 24th September, at low water, the float had reached a point 11·35 miles below the Northern Outfall Sewer, and on the succeeding high water, on the morning of the same day, it was 2·15 miles below the Northern Outfall Sewer. Early in the morning of the 27th September, at high water, the float was in Woolwich Reach, 2·92 miles above the Northern Outfall Sewer, and on the succeeding low water it had reached a point of 12·85 miles below the Northern Outfall Sewer, or was opposite the Northfleet Mill. On the night of the same day, at low water, it had descended the river to a point 16·10 miles below the Northern Outfall Sewer. On the morning of the 29th September, being the period of high spring tide, at high water the float had reached a point 4·40 miles above the Northern Outfall Sewer, and on the succeeding low water descended to a point 11·75 miles below the Northern Outfall Sewer. On the morning of the 1st October, at high water, the float was 1·00 mile above the Northern Outfall Sewer, and at the succeeding low water was 14·75 miles below the Northern Outfall Sewer. At high water on the morning of the 4th October, the float was 4·00 miles below the Northern Outfall Sewer, and on the succeeding low water was 12·25 miles below the Northern Outfall Sewer. In the afternoon of the 6th October, being the period of neap tide, at high water, the float was 0·20 of a mile above the Northern Outfall Sewer, and on the succeeding low water of the following morning it was 10·65 miles below the Northern Outfall Sewer. At high water on the night of the 7th October, the float was 0·78 of a mile below the Northern Outfall Sewer, and on the early morning of 8th October, it descended down the river and reached a point at low water 10·82 miles below the Northern Outfall Sewer, and reascended on the flood tide to a point 2·13 miles below the Northern Outfall Sewer. On the 10th October, in the early morning, at high water, the float was 2·18 miles below the Northern Outfall Sewer, and in descending the river a fog came on, and the precise position to which the float descended could not be seen; although the observers never lost sight of the float, they were unable to see the shore until the float again returned at high water, when it reached a point 1·10 miles below the Northern Outfall Sewer. At high water on the morning of the 13th October, the float was 0·75 of a mile below the Northern Outfall Sewer, and on the descending tide the float was lost in a fog, but was found on the same tide, just before low water, by the observers in the steam-tug "Toby," and at low water it descended to a point 15·40 miles below the Northern Outfall Sewer. On the return tide in the afternoon of the same day, at high water, the float was 1·50 miles below the Northern Outfall Sewer. On the morning of the 14th October, being the period of high-water spring tide, the float was 0·80 of a mile below the Northern Outfall Sewer, and on the succeeding low water had descended to a point 14·75 miles below the Northern Outfall Sewer. On the morning of the 16th October, at high water, the float was 0·43 of a mile above the Northern Outfall Sewer, and at low water on the same morning it was 10·82 miles below the Northern Outfall Sewer. On the morning tide of the 17th October the float had made considerable progress up the river, so that at high water it was found at a point opposite Greenwich Station, being 6·86 miles above the Northern Outfall Sewer, and on the succeeding low water it was 6·22 miles below the Northern Outfall Sewer. At high water on the morning of the 19th October, the float was 3·99 miles above the Northern Outfall Sewer, and on the succeeding low water was 6·98 miles below the Northern Outfall Sewer. On the morning of the 21st October, being the period of neap tide, at high water, the float had descended to a point 0·65 of a mile below the Northern Outfall Sewer, and on the succeeding low water, in the afternoon of that day, was 9·63 miles below the Northern Outfall Sewer. On the morning of the 22nd October, at high water, the float was 1·40 miles below the Northern Outfall Sewer, and on the succeeding low water of the same day it was at a point 10·93 miles below the Northern Outfall Sewer. At low water in the morning of the 24th October, the float was 14·35 miles below the Northern Outfall Sewer, and on the succeeding high water had reached a point 2·15 miles below the Northern Outfall Sewer, when a gale arose and the observations were for a time suspended. The float was again put into the river at low water, on the afternoon of the 25th October, at the same point at which it had arrived at low water in the morning of the 24th October. It ascended the river, and reached a point, in the early morning of the 26th October, 1·70 miles above the Northern Outfall Sewer, when the float was again lost in a fog. In the afternoon of the same day, at high water, it was put into the river at the same place it had reached in the early morning high water, and descended on the ebbing tide to a point 11·87 miles below the Northern Outfall Sewer, and on the succeeding tide, in the morning of the 27th October, it had reached a point at high water 4·85 miles above the Northern Outfall Sewer. At high water on the morning of the 28th October, being the period of spring tide, the float was just below Millwall Dock entrance, 7·86 miles above the Northern Outfall Sewer, and on the succeeding low water, in the morning of the same day, reached a point in Erith Rands 5·26 miles below the Northern Outfall Sewer. On the succeeding flood tide the float reached a point in Greenwich Reach above the Greenwich Gasworks, 6·98 miles above the Northern Outfall Sewer, when this observation was concluded.

It will be observed that in the 36 days this float was in the river, instead of descending the river, it ascended to a point 6·98 miles above that at which it was inserted It will also be observed that in the 32 days in which there was no break, that is, between the 22nd September and the 24th October, the float had descended but 2·15 miles down the river. It will also be observed that in the two lunations ending the 21st October, on the morning tide of the 21st October the progress down the river had been but 0·65 of a mile, and in the afternoon tide of the same day the position of the float exactly corresponded to that at which it was put in at the commencement of the observations, or was opposite the Northern Outfall Sewer at Barking.

*No. 5 Float.*

No. 5 float was put into the centre of the river, three hours after high water, opposite the Northern Outfall Sewer, at 10h. 50m. in the morning of the 22nd September, being the period of neap tide. On the ebb tide it passed down the river 4·95 miles below the Northern Outfall Sewer, and on the succeeding flood tide reached a point in the upper part of Blackwall Reach, 6·30 miles above the Northern Outfall Sewer. At low water on the morning of the 24th September, the float had reached a point 4·80 miles below the Northern Outfall Sewer, and on the succeeding high water it had travelled to a point 7·15 miles above the Northern Outfall Sewer. At high water on the morning tide of the 27th September. the float had reached a point just below Millbank Pier, 14·20 miles above the Northern Outfall Sewer, and on the succeeding low water descended to a point 0·07 of a mile below the Northern Outfall Sewer. On the morning of the 29th September, being the period of high spring tide, the float had reached Putney Bridge, 18·85 miles above the Northern Outfall Sewer, and at the succeeding low water it was still 3·85 miles above the Northern Outfall Sewer. At high water on the morning of the 1st October, the float had reached a point above Putney Bridge, 19·70 miles above the Northern Outfall Sewer, and on the succeeding low water was in Bugsby's Reach 4·55 miles above the Northern Outfall Sewer. On the morning of the 4th October, the float had reached a point near the Victoria Railway Bridge, 15·40 miles above the Northern Outfall Sewer, and on the succeeding low water, in the afternoon of the same day, it was still 2·45 miles above the Northern Outfall Sewer. At high water on the morning tide of the 5th October, the float was 14·25 miles above the Northern Outfall Sewer, near Millbank Pier, and on the ebb tide it descended the river to a point 4·75 miles above the Northern Outfall Sewer. Shortly after the return of the float upon the flood tide, it was taken out, as it was found that No. 3 float was in such close proximity, it was not worth while to continue two floats running over the same course, and this float was started, after this date, as No. 7 float. The observations which have been made with reference to No. 3 float, after this period, will apply to No. 5 float.

It will be observed that, in the 13 days these observations were going on, counting from high water succeeding the period when the float was put in the

river to the last high water observed, the float had made a progress up the river, in the 13 days, of 7·95 miles.

*No. 6 Float.*

No. 6 float was put into the centre of the river at low water, opposite the Northern Outfall Sewer at 2h. 40m. in the afternoon of the 22nd September, it being the period of neap tide. It was carried by the flood tide to a point 10·18 miles above the Northern Outfall Sewer, and on the succeeding low water in the morning of the 23rd September, it had reached the same position as that at which it was started. On the succeeding flood tide a fog came on and the float was lost sight of; but in the afternoon tide of the same day it was started at a point equivalent to low water at the Northern Outfall Sewer, and on the succeeding high water on the night of the same day, the 23rd September, it had reached a point 11·75 miles above the Northern Outfall Sewer. On the morning of the 24th September, at low water, the float was again at the same position from which it was started, viz., opposite the Northern Outfall Sewer, and on the succeeding high water it reached a point 11·18 miles above the Northern Outfall Sewer. Early in the morning of the 27th September, at high water, the float had reached a point just below Putney Bridge, or 18·70 miles above the Northern Outfall Sewer, and at low water in the morning of the same day it was 4·70 miles above the Northern Outfall Sewer. On the morning of the 29th September, being the period of high water spring tide, the float had reached at high water, Hammersmith Bridge, a point in the river 20·80 miles above the Northern Outfall Sewer, and on the succeeding low water was found at a point 6·30 miles above the Northern Outfall Sewer. At high water on the morning of the 1st October, the float was at Putney Bridge, 18·71 miles above the Northern Outfall Sewer, and at low water about noon on the same day it was 4·15 miles above the Northern Outfall Sewer. On the morning of 4th October the float was at Vauxhall, being 14·28 miles above the Northern Outfall Sewer, and on the succeeding low water in the afternoon of the same day, it was 2·95 miles above the Northern Outfall Sewer. In the afternoon of the 6th October, being the period of neap tide, at high water, the flood was at Vauxhall, being 13·53 miles above the Northern Outfall Sewer, and on the succeeding tide of the morning of the 7th October, it was 4·35 miles above the Northern Outfall Sewer. At high water about mid-day on the 8th October the float was at the Victoria Railway Bridge, 15·45 miles above the Northern Outfall Sewer, and at low water in the afternoon of the same day it reached a point 3·70 miles above the Northern Outfall Sewer. At high water in the morning of the 12th of October, the float was at Putney, 18·87 miles above the Northern Outfall Sewer, and at low water in the morning of the same day it was 6·08 miles above the Northern Outfall Sewer. On the morning of the 13th October at high water, the float was 19·80 miles above the Northern Outfall Sewer, and at low water in the morning of the same day was 6·03 miles above the Northern Outfall Sewer. On the morning of the 14th October, being the period of high water spring tide, at high water the float was 20·15 miles above the Northern Outfall Sewer, and at low water in the morning of the same day, it was 7·10 above the Northern Outfall Sewer. At high water on the morning tide of the 15th October, the float had ascended the river to a point 19·30 miles above the Northern Outfall Sewer, and on the succeeding low water, in the morning of the same day, it was in Blackwall Reach at a point 5·92 miles above the Northern Outfall Sewer. At high water in the morning of the 16th October the float was at a point in the river between Chelsea and Battersea Bridge, 16·85 miles above the Northern Outfall Sewer, and on the succeeding low water, in the morning of the same day, it was in Bugsby's Reach, 4·75 miles above the Northern Outfall Sewer. At high water, on the morning of the 17th October, the float was 17·02 miles above the Northern Outfall Sewer, and at low water on the descending tide in the same morning, it was in Bugsby's Reach, 4·39 miles above the Northern Outfall Sewer. After this the float began to descend the river, and at low water at mid-day on the 18th October, it had reached a point 1·0 mile above the Northern Outfall Sewer, and on the succeeding high water in the afternoon of the 18th October it was at Waterloo Bridge, 12·75 miles above the Northern Outfall Sewer. On the following ebb tide a fog came on and this float was lost sight of. It was, however, started again on the flood tide in the afternoon of the 19th October, being placed in the same position with reference to No. 7 float, having worked continuously throughout this period. At high water on the afternoon of the 19th October, the float was in the Upper Pool, 10·89 miles above the Northern Outfall Sewer, and on the succeeding low water, in the early morning of the 20th October, it had reached a point 0·65 of a mile below the Northern Outfall Sewer. At high water on the morning of the 21st October, being the period of neap tide, the float was 7·90 miles above the Northern Outfall Sewer, and on the succeeding low water, on the afternoon of the 21st October, was 3·25 miles below the Northern Outfall Sewer. On the morning of the 22nd October, at high water, the float was nearly opposite Greenwich, at a point 6·62 miles above the Northern Outfall Sewer, and at low water, in the afternoon of the 22nd October, it reached a point 2·97 miles below the Northern Outfall Sewer. On the succeeding high water on the night of the 22nd October, the float was in Limehouse Reach, 8·37 miles above the Northern Outfall Sewer, and so the float ascended and descended the river until low water in the morning of the 24th October, when it reached a point 6·53 miles below the Northern Outfall Sewer. On the succeeding high water, on the morning of the 24th October, the float had reached a point near the Millwall Dock entrance, being 8·00 miles above the Northern Outfall Sewer. Shortly after this a gale came on and the observations with this float were discontinued.

It will be observed that in the 31 days this float was in the river, counting from low water to low water, it progressed down the river 6·53 miles. In the first 26 days, in which there was no break in the observations with this float, it had advanced at low water 1·00 mile up the river, or if two complete lunations are taken, ending in the afternoon on the 21st October, at low water, the float had descended 3·25 miles down the river.

*No. 7 Float.*

No. 7 float was put into the river at half flood, opposite the Northern Outfall Sewer, at 6 A.M. on the 6th October, being the period of neap tide. On the completion of its flow up the river, at high water, it was in Bugsby's Reach, 4·40 miles above the Northern Outfall Sewer, and on the succeeding low water, on the 6th October, it descended to a point in Erith Rands, 5·10 miles below the Northern Outfall Sewer. On the afternoon tide of the 7th October, the float had reached a point at high water, near Millwall Dock entrance, 8·00 miles above the Northern Outfall Sewer, and at low water on the succeeding morning tide of the 8th October, it had descended to a point near Rainham Creek, 3·55 miles below the Northern Outfall Sewer. On the early morning tide of the 10th October, at high water, the float was near the Thames Tunnel, being 10·00 miles above the Northern Outfall Sewer, and at low water on the succeeding tide of the 10th October it had descended to a point in Erith Reach, 3·60 miles below the Northern Outfall Sewer. On the early morning tide of the 12th October the float had reached Blackfriars, or was at a point 12·20 miles above the Northern Outfall Sewer, and on the succeeding low water on the morning of the 12th October it was in Halfway Reach, 1·50 miles below the Northern Outfall Sewer. On the early morning tide of the 13th October, at high water, the float was 14·70 miles above the Northern Outfall Sewer, being opposite Pimlico Pier, and on the succeeding low water was in Barking Reach, 0·10 of a mile above the Northern Outfall Sewer. At high water, in the morning of the 14th October, being the period of high water spring tide, the float was at Battersea Park Pier, 15·40 miles above the Northern Outfall Sewer. On the succeeding low water, on the morning of the 14th October, it was in Woolwich Reach, 3·00 miles above the Northern Outfall Sewer, and on the following high water, in the afternoon of the 14th October, it was at Battersea Bridge, 16·45 miles above the Northern Outfall Sewer, and on the succeeding low water it had descended to a point opposite North Woolwich Station, being about 2·00 miles above the Northern Outfall Sewer. At high water on the afternoon tide of the 16th October, the float was at Chelsea Bridge, being 16·40 miles above the Northern Outfall Sewer. On the succeeding low water, on the night of the 16th October, the float was in Woolwich Reach, 3·15 miles above the Northern Outfall Sewer. On the 18th October, on the afternoon tide, the float had reached a point about Charing Cross, 12·97 miles above the Northern Outfall Sewer. In the afternoon of the 18th October, the float was lost sight

App. R.

of in Blackwall Reach for about four hours, but was found on the flood tide at North Woolwich Station. It was clear, however, from the position in which the float was found that it had continued to travel its proper course, and on the succeeding high water, in the early morning of the 19th October, it had reached a point in Barking Reach 1·40 mile below the Northern Outfall Sewer, and so it continued to travel backwards and forwards until the morning tide of the 21st October, being the period of neap tide, when at high water it was near the Millwall Dock entrance, or 8·00 miles above the Northern Outfall Sewer, and on the succeeding low water in the afternoon of the 21st October, it had descended to a point near the mouth of the Beam River, being 2·80 miles below the Northern Outfall Sewer. On the morning of the 22nd October, at high water, the float was in Greenwich Reach, 7·00 miles above the Northern Outfall Sewer, and on the succeeding low water, in the afternoon of the same day, it was in Halfway Reach, 3·32 miles below the Northern Outfall Sewer, and so the float continued to ascend and descend the river, until at low water, on the morning of the 24th October, it was below Erith, at a point about 5·25 miles below the Northern Outfall Sewer, and on the succeeding high water of the tide on the morning of the 24th October, it reached a point in Greenwich Reach, 6·63 miles above the Northern Outfall Sewer, when a gale came on to blow, and the experiment was discontinued.

It will be seen, counting from high water to high water, that in the eighteen days this float was in the river, it made a progress of 2·23 miles up the river. If we take one period of similar lunation, ending on the 20th October, it will be seen that the upward progress of the float was 3·50 miles.

*No.* 8 *Experimental Float.*

No. 8 experimental float was put into the river at Teddington, at high water, at 3h. 40m. in the afternoon of the 27th October 1882. On the ebb tide of that afternoon it floated down to Vauxhall, being a distance of 15·49 miles. On the return tide, early in the morning of the 28th October, at high water it had reascended the river a distance of 6·75 miles above the point which it had reached at the previous low water. On the succeeding ebb tide of the 28th October, it floated down the river a distance of 15·16 miles, and had reached a point in the upper part of Blackwall Reach. On the following flood tide, in the afternoon of the 28th October, it was carried up the river 11·02 miles, to a point above Chelsea Bridge, and on the succeeding ebb tide, on the afternoon of that day, it descended the river 15·52 miles, to a point in the lower part of Woolwich Reach, being 1·74 miles above the Northern Outfall Sewer. On the succeeding flood tide, at high water, in the early morning of the 29th October, the float had passed up the river 11·03 miles, being at Waterloo Bridge, and at low water on the succeeding ebb tide of the same day, it passed down the river 14·22 miles, or to the "Leather Bottle," at Crossness, 1·45 miles below the Northern Outfall Sewer. On the high water of the succeeding flood tide it passed up the river 10·61 miles, being opposite the Regent's Canal Dock, 9·16 miles above the Northern Outfall Sewer. The experiments at this point were discontinued on account of the rough weather.

In the two days that this float had been floating down the river it will be observed that it descended a distance of 20·98 miles.

*No.* 9 *Experiment, or Simultaneous Observations.*

On the 3rd November 1882, three floats were put into the river at high water at the following places, viz., one at Vauxhall Bridge, a second in the upper part of Limehouse Reach, near the West India Dock west entrance, and a third 150 yards above the Metropolitan Southern Outfall Sewer at Crossness.

The first of these floats descended upon the ebb tide 13·70 miles, or to a point in Galleon's Reach; the second 11·78 miles, or to near the mouth of the Beam River in Halfway Reach; and the third 11·14 miles, or to a point near the lower part of Northfleet Hope. On the succeeding flood tide the first float reascended the river 8·51 miles, the second 9·48 miles, and the third 8·11 miles

On the 6th November four floats were put into the river at high water at the following points, viz., the first at Vauxhall Bridge; the second in the upper part of Limehouse Reach, near the West India Dock west entrance; the third at a point 150 yards above the Metropolitan Southern Outfall at Crossness; and the fourth in the lower part of Gravesend Reach, just above Shorne Mead Battery. On the ebb tide the first float descended a distance of 12·62 miles, or to a point near Woolwich Ferry; the second 11·72 miles, or to a point near the mouth of the Beam River; the third 10·92 miles or to a point near the lower part of Northfleet Hope; and the fourth 13·21 miles, or to about three-quarters of a mile below London Stone. On the return flood tide, the first float reascended the river 9·42 miles, or to a point near the Tower Subway; the second 11·69 miles, or to a point near the West India Dock west entrance; the third 9·70 miles, or to a point in the lower part of Halfway Reach; and the fourth 8·41 miles, or to a point in the upper part of Sea Reach.

On the 7th November, the four floats were again put into the river at high water, at the same points as on the previous day. The first float descended 12·65 miles, or to a point in the lower part of Woolwich Reach; the second 11·72 miles, or to a point in Halfway Reach; the third 11·72 miles, or to a point opposite Rosherville Pier; and the fourth 12·32 miles, or to a point near London Stone. On the return flood tide the first float reascended the river 9·48 miles, or to a point near the Tower Subway; the second float 11·07 miles, or to a point in Limehouse Reach; and the third float 10·32 miles, or to a point opposite Rainham Creek. The fourth float on this occasion did not reascend the river on account of the rough weather.

The last two days' observations show that the range of the tide with No. 1 float on the flood tide, in the upper part of the river, was 9·45 miles; No. 2 float, somewhat lower in the river than No. 1 float, 11·38 miles; No. 3 float, lower still in the river, 10·01 miles; and No. 4 float, in the lower part of the river, 8·41 miles;* while on the ebb tide No. 1 float in the upper part of the river, had an average range of 12·63 miles; No. 2 float, at a lower point in the river, 11·72 miles; No. 3 float, still lower in the river, 11·32 miles; and No. 4 float, in the lower part of the river, 12·76 miles.

*No.* 10 *Experiment.*

In this experiment two sets of floats were used, viz., deep floats, such as were used in the observations Nos. 1 to 7, and surface floats, the object being to ascertain the effect of mixture by the ebb and flow of the tides in the river, and the relative velocity of these floats in various parts of the river.

The first experiment consisted in putting into the river at low water, at London Stone, on the 29th October, at 8·25 A.M., a float of the same kind as used in the observations Nos. 1 to 7. So soon as the float had been put into the river, samples of water in duplicate were drawn at one foot below the surface, and also at half the depth of the river, in order to ascertain the amount of chlorine in the water. When the float had passed on the flood tide as far as Middle Blythe Buoy, No. 2 samples of water were taken alongside the float in a similar way to those taken at the starting; and when the float had reached Cliffe Creek, a distance of 11·00 miles from the point of starting, No. 3 samples of water were taken; and when the float had come to rest at high water, after having gone up the river a distance of 13·40 miles, or to a point in Gravesend Reach, No. 4 samples of water were taken. On the morning tide of the 30th October, the same float was put into the river at low water in Gravesend Reach, at the same point that it had reached at high water on the morning of the preceding day. No. 5 samples of water were taken alongside the float after it was placed in the river, both below the surface and at half the depth of the river, for the purpose of chlorine tests. When the float had passed up the river as far as Gray's Causeway, No. 6 samples of water were drawn; and as it proceeded up to Cold Harbour, No. 7 samples were drawn, and at the end of its course at high water, near the Metropolitan Southern Outfall, having travelled up the river 14·25 miles, No. 8 samples were drawn. On the following day, the 31st October, at low water, the float was again put into the river, near the Metropolitan Southern Outfall Sewer, at the same point it had reached at high water on the preceding day, and before starting up the river No. 9 samples of water were drawn; and as the float passed up the river, when it reached a point near North Woolwich, No. 10 samples of water were drawn. As the float travelled still farther up the river, and off the Ship Hotel at Greenwich,

* This was a single observation

No. 11 samples of water were drawn; and at high water, when opposite Limekiln Dock, No. 12 samples of water were drawn, the float having travelled a distance of 11·25 miles on its flow up the river. On the following day, the 1st November, the float was again put into the river at low water, at the same spot as that at which it had arrived on the previous day tide, and No. 13 samples of water were drawn. After the float had reached London Bridge, No. 14 samples of water were taken alongside of it, and at high water, when it had arrived at Vauxhall Bridge, having travelled up the river 5·20 miles, No. 15 samples of water were drawn. On the following day, the 2nd November, a float consisting of a copper ball with bucket suspended by a chain was used, the bottom of the bucket being immersed 5 feet from the surface. The float was put in at low water at the same spot the float had reached at high water on the previous day, and No. 16 samples of water were drawn alongside of it, and at high water the float arrived at Wandsworth Bridge, having travelled a distance of 3·53 miles up the river, when No. 18 samples of water were drawn. On the following day, the 3rd November, the float was again put into the river at low water at Wandsworth Bridge, being the same place it reached on the preceding day tide at high water, and No. 19 samples of water were taken alongside of it. At high water it had passed up to the mouth of the Beverley Brook, a distance of 1·45 mile, when No. 20 samples of water were taken. At low water on the following day, the float was again put into the river opposite Beverley Brook, being the same point as it had reached on the preceding day at high water, when No. 21 samples of water were drawn. The current of land water down the river being so strong, this float only made a swim of 300 yards during the flow of the tide, and when taken out No. 22 samples of water were taken.

At high water on the 4th November, a surface float was put into the river at Teddington Weir at 9.37 A.M., when No. 23 samples of water were taken alongside of it. When the float had flowed down to the top of Chiswick Eyot, No. 24 samples of water were drawn, and at low water the same day the float had arrived at a point opposite the City of London Schools, having travelled a distance of 17·80 miles, when No. 25 samples of water were taken. On the morning tide of the 5th November, at high water, the float was again put into the river opposite the City of London Schools, when No. 26 samples of water were drawn. On the float arriving at Greenwich Pier, No. 27 samples of water were drawn, and as the float swam down the river, opposite the Albert Dock entrance, No. 28 samples of water were drawn, and at low water the float had arrived at the "Leather Bottle" at the top of Halfway Reach, having travelled a distance of 14·00 miles down the river, when No. 29 samples of water were drawn. On the morning tide of the 6th November, the float was again put into the river at high water, at the "Leather Bottle," being the same point as it had reached on the previous day at low water, when No. 30 samples of water were taken alongside of it. As the float passed down the river, when near the middle of Erith Rands, No. 31 samples of water were drawn, and on arriving at the middle of St. Clement's Reach No. 32 samples of water were taken. At low water the float had reached a point opposite the mouth of the Medway Canal, having travelled a distance of 13·67 miles down the river, when No. 33 samples of water were taken. On the morning tide of the 7th November the float was again put into the river opposite the Medway Canal, being the point at which it had arrived on the preceding day at low water, when No. 34 samples of water were drawn, and as the float proceeded down the river in the Lower Hope, No. 35 samples of water were drawn, and at Canvey Island Beacon, No. 36 samples of water were drawn. At low water the float had arrived at London Stone, having travelled down the river a distance of 14·50 miles, when No. 37 samples of water were drawn.

It will be seen that, when working up the river the float only ascended from London Stone in the seven-day tides, a distance of 50 miles, and came back from Teddington, a distance of 60 miles, on four tides.

On the 30th and 31st October, and 1st, 2nd, and 3rd November, while the floats were working from Gravesend Reach up the river, a surface float was tested alongside a deep float, and when working down the river, from the 4th to the 7th November, a surface float was again tested alongside a deep float, in order to ascertain the relative rates of velocity, with the following results:—

| Date. | Deep Float ran up River. | Surface Float ran up River. |
|---|---|---|
| | Miles. | Miles. |
| October 30th | 14·25 | 13·01 |
| ,, 31st | 11·08 | 11·25 |
| November 1st | 5·14 | 5·20 |
| ,, 2nd | 3·53 | 3·48 |
| ,, 3rd | 1·45 | 1·44 |

The average of the speed of the deep floats up the river was 7·09 miles, while the average of the surface floats was 6·87 miles per tide. When flowing down the river from a point opposite the City of London Schools, the results were:—

| Date. | Deep Float ran Down River. | Surface Float ran Down River. |
|---|---|---|
| | Miles. | Miles. |
| November 5th | 13·88 | 14·00 |
| ,, 6th | 12·47 | 13·67 |
| ,, 7th | 13·90 | 14·50 |

On an average of these experiments, the deep floats passed down the river 13·41 miles, while the surface floats passed down in the same time 14·05 miles per tide, so that it will be seen on ascending the river, on an average, the surface floats moved with less velocity than the deep floats; but on descending the river, the surface floats moved with the greatest velocity.

*Horizontal Oscillation of the Tides in the River Thames.*

In the experiments made with the floats Nos. 1 to 7, which were immersed 12 feet in the tidal way between the 17th September and the 1st November inclusive, these floats completed 456 complete swims on the flood tide, and 450 complete swims on the ebb tides, in addition to which there was a swim of half a tide on the flood and two half-tides upon the ebb, which were not taken into account in ascertaining the average distance which was traversed by the floats, but they have an influence with reference to the position of the floats in the river during the period of observation. Taking the whole of the experiments upon flood tides, the average distance travelled by the floats upon the flood tides was found to be 12·60 miles per tide, and the average distance travelled by the floats upon all the ebb tides was found to be nearly the same, viz., 12·64 miles per tide. If, however, the distances traversed are taken at different periods, they vary. From the 17th September to the 30th September, the average distance traversed on the floods was 13·46 miles, and on the ebbs 13·29 miles per tide. Between the 1st and 16th October, the average distance travelled on the floods was 12·51, and on the ebbs 12·40 miles per tide. From the 17th October to the 1st November the average distance travelled on the floods was 11·95 miles, and on the ebbs 12·41 miles per tide. Taking the observations made with the recording machines upon the vertical range of the tides, it is found that there is a difference of time between ebb and flow, and the length of flood and ebb at Teddington, Deptford, Erith, Gravesend, and Southend, as shown by the following figures:—

| | Flood. | Ebb. | Whole Tide. |
|---|---|---|---|
| | H. M. | H. M. | H. M. |
| Teddington | 2 3 | 10 10 | 12 13 |
| Deptford | 5 30 | 6 55 | 12 25 |
| Erith | 5 51 | 6 34 | 12 25 |
| Gravesend | 5 57 | 6 27 | 12 24 |
| Southend | 6 3 | 6 22 | 12 25 |

In all cases the period of ebb is longer than that of flow, but the times vary in different parts of the river.

The accompanying Table, No. 1, shows the distance the floats passed over on every tide up and down the river, and the diagrams show the position of these floats in every part of the river during the period of observation.

## TABLE No. 1.

TABLE of OBSERVATIONS showing the DISTANCE FLOATS IMMERSED 12 FEET TRAVELLED on the FLOOD and EBB TIDES in the RIVER THAMES, from the 17th SEPTEMBER to the 1st NOVEMBER 1882.

| Average of No. 5 float from 22nd September to morning tide of 5th October | | | | | | | | | | | | | | | | | 13·46 | 13·31 | 13·79 | 14·76 | | | | | | | | |

NOTE.—The figures in No. 5 float observations from the afternoon of the 5th October to the end of the experiment are the same as for No. 3 float. The figures in italics, being only parts of the full tidal flow, are not added in the averages.

*Vertical Range and Mean Level of Tide.*

For many years past the vertical range of the tides, except in the mouth of the river, has been proportionately increasing. This is specially shown in recent years by the increasing number of high tides in the Thames, and also by increased range of tide. From Mr. Redman's Paper in the Minutes of Proceedings of the Institution of Civil Engineers, vol. xlix., the range of tide in the Pool was shown to have increased, between 1800 and 1874, 4 feet, as will be seen from the following figures:—

1800 = 18·0 feet.
1843 = 19·5 ,,
1864 = 20·3 ,,
1866 = 20·6 ,,
1874 = 22·0 ,,

The highest tide on record in the Thames occurred on the 18th January 1881, on which occasion the tide rose to 4 feet 10 inches above Trinity High Water (17·33 above Ordnance Datum) at London Bridge, and 3 feet 9 inches above Trinity High Water (16·25 above Ordnance Datum) at Gravesend. There was a table of high tides in the Thames published in the report of the Government Referees in 1857, which shows that the highest tide on record up to that time occurred on the 12th November 1852, when the tide rose to a level of 3 feet 9 inches above Trinity high-water mark (16·25 above Ordnance Datum) at the Wapping entrance to the London Docks. Since 1873 the tides have risen to a higher point than before, and culminated in the high tide of January 1881. It also appears that in the highest parts of the tidal portion of the river, as at Teddington, the range of high water has increased, for in a phamphlet by Dr. Sayer, published in 1858, the range of forty-five spring tides at Teddington is given as 2 feet 5 inches, and neap tides 1 foot 0½ inch. He also gave the mean rise of the same number of spring tides as 10 feet 1 inch at Strand-on-the-Green, and at Blackfriars Pier 17 feet 6½ inches, and the rise of an equal number of neap tides as 8 feet 8 inches at Strand-on-the-Green, and 15 feet 4¾ inches at Blackfriars Pier.

The observations taken in September, October, and November 1882, show the average vertical range of the tide at the following places to be—

| | Feet. |
|---|---|
| Southend Pier - - | 14·36 |
| Gravesend Pier - - | 16·57 |
| Erith Pier - - - | 17·55 |
| Deptford Cattle Market - | 18·29 |
| Teddington Lock - - | 3·70 |

In the same period, the range of a single tide on the 28th September 1882, was—

| | Feet. |
|---|---|
| Southend Pier - - | 19·2 |
| Gravesend Pier - - | 21·4 |
| Erith Pier - - | 22·7 |
| Deptford Cattle Market - | 23·8 |
| Teddington Lock - - | 9·1 |

The greatest range from highest high water to lowest low water on different tides was—

| | Feet. |
|---|---|
| Southend Pier - - | 19·6 |
| Gravesend Pier - - | 22·3 |
| Erith Pier - - - | 27·5 |
| Deptford Cattle Market - | 28·1 |
| Teddington Lock - - | 12·2 |

The mean level of the tide in the river at the London Docks is stated in Mr. Redman's Paper, before referred to, so be 2 feet 6 inches above Ordnance Datum. In the observations made on the river for the Commissioners of Sewers, in one month, in June and July 1849, it was stated to be:—

| | Feet. | |
|---|---|---|
| Deptford - | 2·02 | above Ordnance Datum. |
| London Bridge - | 2·44 | ,, ,, ,, |
| Battersea - | 2·50 | ,, ,, ,, |

The observations made on the river in the months of September, October, and November, 1882, show that the mean tides were as under:—

| | Feet. | |
|---|---|---|
| Southend Pier - | 1·89 | above Ordnance Datum. |
| Gravesend Pier - | 1·94 | ,, ,, ,, |
| Erith Pier - - | 1·96 | ,, ,, ,, |
| Deptford Cattle Market | 1·98 | ,, ,, ,, |
| Teddington Lock - | 11·00 | ,, ,, ,, |

In the case of Teddington, the level has been arrived at from observing the levels in a number of tides when the volume of water has been about that of the mean flow of the river, for at this high point in the river the volume of upland water coming down very materially affects the level of the tide.

The observations on the range of the tide show that low water at Southend, on an average of all the tides between September and November, 1882, is 1·87 feet higher than Deptford. On the 27th September, 1882, low water at Deptford was 2·5 feet lower than at Southend. Low water at Gravesend, on the average, was 1·06 feet lower than at Southend, and low water at Erith 1·52 feet lower than at Southend. High water at Southend, on an average of all the tides from September to November, 1882, was 2·06 feet lower than high water at Deptford. On the 28th September, 1882, high water at Deptford was 2·60 feet above that at Southend. On the average of all the experiments, high water at Gravesend was 1·16 feet above that at Southend, and at Erith 1·66 feet above that at Southend.

---

Previous Observations which have been made in the River Thames with a view to ascertain the Range of the Tides in regard to the question of the Sewage Outfalls for the Metropolis.

It appears that some of the earliest investigations, of which there is any record, of the horizontal range and velocity were made for the Corporation of London, who were then the Conservators of the Thames, by Sir John Rennie, C.E., and W. C. Mylne, Esq., C.E. The observations were made in 1832 with reference to the velocity of flow between the bridges. In these experiments floats of 7 feet, 4 feet, and 2 feet in length were used, and from the results of the experiments, it is shown that the greatest progress was made on the half flood and half ebb, and the least nearest low and high water. In these experiments the deeper float sometimes moved with a greater velocity than the shallower float, and, *vice versâ*, sometimes the shallowest float moving with the greatest velocity.

In 1849 the Commissioners of Sewers for the Metropolis instituted a series of tidal experiments. At this period it does not appear that any observations were made upon the horizontal movement of the tides through the river, but careful observations were made for a month, from the 19th June to the 19th July, upon the vertical range, with gauges fixed at Deptford, London Bridge, and Battersea. After it had been determined by the Commissioners of Sewers to convey the sewage into Galleon's Reach, the first series of tidal observations were made under the direction of Mr. Frank Foster. These observations were carried out by Mr. John Phillips and his assistant, Mr. William Betts, junior. A diagram of these float observations was published in the Government Report upon the Main Drainage of the Metropolis in 1857. At a later period in April 1858, the engineers appointed by the Metropolitan Board of Works, viz., Messrs. Bidder, Hawksley, and Bazalgette, reported that the diagram printed by the Government Referees was in error, and they produced a diagram of these observations, from which it will be seen that in seventy-four runs up and seventy-four runs down the river, from the 20th June to 20th August, the average rate of progress up the river was 11·98 miles per tide, and the average rate of progress down the river was 12·64 per tide.* It should be remarked, however, in reference to these observations, that they are taken so as to give an undue advance down the river, for forty-one of the swims occurred on tides that were falling, while thirty-three only occurred on rising tides. If we take an equal number of tides from the neap tide between the 23rd and 24th July 1851, and count back ten tides, the float at high water is 3¼ miles below Barking Creek, and then if we count ten tides forward from the tide in question, the float is 4¼ miles below Barking Creek, having descended the river but one mile in twenty-one tides. At high water at the period of spring tides on the 15th August the float was 2¼ miles above Barking Creek. Counting back ten tides from this tide, the float was a point 4¾ miles above Barking Creek, and counting forward ten tides from the same tide, the float had advanced to a point 9 miles below Barking Creek, or in the twenty-one

* The float used in these experiments was immersed in the water about 5 feet 6 inches.

App. R.

tides it had advanced 13¾ miles down the river. Taking the sum of these forty-two tides the float descended 14¾ miles down the river, or just over one-third of a mile per tide.

Sir J. W. Bazalgette, when giving evidence against the Great London Drainage Bill in June 1853, said that as a result of Mr. Frank Foster's Tidal Observations—Question 2723—"The sewage at Greenwich "would at certain times, even though discharged at "high water, or within two hours of high water, "return up to six miles above that point, which is "near London Bridge."

In a report of the engineers to the Metropolitan Commissioners of Sewers, 5th March 1855, it is stated that some recent float experiments show that a float put in the river at the Earl Sluice, at low water, passed up the river on the flood to Battersea Old Church, a distance of 9½ miles, while another float put in at Woolwich, was carried up on the flood tide as far as Lambeth.

In June 1856, Captain Burstal was instructed by the First Commissioner of Her Majesty's Works to make some tidal observations in the River Thames, with a view to advise him as to the effect of discharging sewage at the proposed Northern Outfall Sewer at Barking, and the Southern Outfall in Plumstead Marshes, at a point opposite the proposed Barking Outfall. The result of these observations clearly showed that the sewage, if discharged at these points, would return at certain states of the tide up the river above the point of outfall, and in consequence of this report of Captain Burstal, a scheme was prepared for removing the outfalls lower down the river, or to Rainham Creek. After it had been determined by the Metropolitan authorities to shift the outfalls to this point, and they sought the sanction for the work, Sir Benjamin Hall, the First Commissioner of Public Works, referred the whole question to the Government Referees, Captain Douglas Galton, Mr. James Simpson, C.E., and Mr. T. E. Blackwell, C.E. The inhabitants of Erith and its neighbourhood, alarmed at the prospect of the sewage being turned into the river so near to them, instructed Mr. Homfray, an engineer, to make a series of tidal observations. These observations consisted first in ascertaining the range of oscillation of the tide from the points of proposed outfall at Rainham Creek, as well as the vertical range in different parts of the river. After the observations had been made near the points of the proposed outfall, further observations were made by the same engineer in Sea Reach. The observations in Erith Reach show that even at this point the sewage discharged would have found its way back into the Metropolitan District. A full report is to be found in the Appendix to the Government Referees' Report of 1857, page 353. There is also a chart showing the direction taken by the floats, as well as a diagram showing the vertical range of the tides. It may be pointed out that Messrs. Bidder, Hawksley, and Bazalgette, in their Report in 1858, mentioned that the diagram of the vertical range of the tides referred to was evidently in error, as low water in the lower part of the river was shown to be higher than in the upper part of the river. The recent observations, as well as others, show that the error was not made by the Government Referees, and that high water at, say, London Bridge, is higher than high water at Sheerness, so low water in the river at London Bridge is absolutely lower than low water at Sheerness.

In 1857 a further series of float observations in the Thames were made by Captain Burstal, on behalf of the Government Referees, which are set forth in a chart which is given in their Report. These observations were made in the lower part of the river.

A series of observations were also made in connexion with the outfall proposed by the late Mr. M'Clean, Past President of the Institution of Civil Engineers, in the German Ocean.

The foregoing are all the tidal observations that are generally known to have been made in the River Thames, in connexion with the horizontal oscillation of the tides in reference to the outfall sewers of the Metropolis.

### Gaugings of the Thames.

The accompanying Table, No. 2, gives the quantities of water, in cube feet per minute, at the various places which have been gauged, to which is added the water supply of the London Water Companies, and the calculated quantity for the area not gauged, so that the accurate quantity of water daily passing down the Thames, during the period the tidal observations were going on, can at once be seen. The area of the Thames Basin actually gauged is 4,878 square miles.

From former surveys of the River Thames Basin, it is shown that the area above Teddington Lock is 3,676 square miles, the total area of the Thames Basin being 5,162 square miles, of which the drainage area of the River Lea constitutes 500 square miles. The quantity of water flowing down the river has been gauged at Seething Wells for a number of years past by Mr. John Taylor, C.E., and most of these records have been published, many of them in the Sixth Report of the Rivers Pollution Commissioners.

It may be mentioned that the dry weather flow of the Thames may be taken at 12 cube feet per minute per square mile, and the average flow at 30 cube feet per minute per square mile, the maximum flow in periods of excessive flood rising to 360 cube feet per minute per square mile.

The Table of Gaugings shows that during the period the tidal observations were going on, except for a few days at the commencement, there was more than an average quantity of water coming down the river.

About the 11th October a wet period commenced, and the result is shown by the large increase in the volume of the water in the river on the 14th October and subsequently, which culminated in the excessively large quantity of upland water passing down the river on the 30th October, after which it greatly diminished, but the river still continued in flood until the end of the tidal experiments.

## APPENDIX U.

*(Put in by Mr. Baldwin Latham, 24th January 1883. See Q. 7525.)*

FORMULÆ for the DETERMINATION from CHLORINE ANALYSES of the RATIO of the FRESH WATER to the SEA WATER in a SAMPLE of the MIXTURE.

Let $a$ represent the amount of chlorine in one volume of sea water.
,, $b$ ,, the amount in an equal volume of fresh water.
,, $c$ ,, the amount in the sample.

Then, if a mixture be made of sea water and fresh water, the amount of chlorine in the mixture will be equal to the volumes of sea water and fresh water multiplied by $a$ and $b$ respectively.

Also, if a mixed sample of sea water and fresh water in unknown proportions be taken, then the component volume of sea water, whatever it may be, multiplied by $a$, together with the volume of fresh water multiplied by $b$, will represent the total amount of chlorine in the mixed sample; that is, will be equal to the volume of the sample multiplied by $c$, or, what is equivalent, the sum of the component volumes of sea water and fresh water multiplied by $c$.

In the sample suppose $V_s$ and $V_r$ to represent the component volumes of sea water and river water respectively, then—

$$V_s \times a + V_r \times b = (V_s + V_r) \times c;$$
$$V_s a + V_r b = (V_s + V_r) c;$$
$$V_s a + V_r b = V_s c + V_r c;$$
$$V_s a - V_s c = V_r c - V_r b;$$
$$V_s (a - c) = V_r (c - b);$$
$$a - c = \frac{V_r}{V_s} (c - b);$$
$$\frac{a - c}{c - b} = \frac{V_r}{V_s}.$$

$\frac{V_r}{V_s}$ represents the ratio in the mixed sample that the fresh water bears to the sea water.

Therefore, in the sample, the ratio of the fresh water to the sea water is equal to $\frac{a - c}{c - b}$.

*Example.*—Suppose a sample, on analysis, was found to contain 251·42 parts of chlorine in 100,000 parts, and that it consists entirely of fresh water and sea water.

Consider the amount of 100,000 parts as the volume of the sample:—

$a$, the chlorine in the component sea water is taken at 1,961 parts per 100,000;

$b$, the chlorine in the fresh water is taken at 1·7 parts per 100,000;

$c$ is found by analysis to be 251·42;

then,—

$a - c = 1961 - 251{\cdot}42 = 1709{\cdot}58$;

$c - b = 251{\cdot}42 - 1{\cdot}7 = 249{\cdot}72$;

the ratio of the fresh water to the sea water $\frac{a - c}{c - b}$ is equal to $1709{\cdot}58 \div 249{\cdot}72 = 6{\cdot}8459875$, &c.; therefore the ratio of the fresh water to the sea water in the sample is 6·8459875 : 1.

*Proof.*—If the sample be re-mixed in these proportions it will be found to contain 251·42 parts of chlorine per volume of 100,000 parts.

The ratio of the fresh water to the sea water is 6·8459875 : 1.

| | Chloriné. |
|---|---|
| 6·8459875 volumes of fresh water at 1·7 parts per volume = | 11·63817875 |
| 1 volume of sea water at 1,961 parts per volume = | 1961·0000 |
| Therefore the mixture of 7·8459875 volumes contains = | 1972·63817875 |

$1972{\cdot}63817875 \div 7{\cdot}8459875 = 251{\cdot}4200$;

thus showing that the sample on being re-mixed in the above proportion would contain 251·42 parts of chlorine.

It will be seen from this proof that no other ratio of composition would give a mixture containing 251·42 parts of chlorine, for, as the ratio of fresh water to the sea water increases, the chlorine in the mixture necessarily diminishes, as may be seen, thus:—

If the ratio be 5 : 1

| | Chlorine. |
|---|---|
| 5 volumes fresh water at 1·7 = | 8·5 |
| 1 volume sea water at 1961 = | 1961·0 |
| the mixture of 6 volumes contains | 1969·5 |

and 1 volume contains 328·2 parts chlorine.

If the ratio be 6 : 1

| | Chlorine. |
|---|---|
| 6 volumes fresh water at 1·7 = | 10·2 |
| 1 volume sea water at 1961 = | 1961·0 |
| the mixture of 7 volumes contains | 1971·2 |

and 1 volume contains 281·6 parts chlorine.

If the ratio be 6·8, &c. : 1 (as before),
one volume of the mixture contains 251·4 parts chlorine, and so on, varying in inverse quantities to the ratio. Therefore there is only one ratio of composition which will produce a mixture containing a given amount of chlorine.

When sewage is mixed with river water in a known proportion, and consequently the quantity of chlorine per 100,000 parts of the mixture is known, the ratio of the river water and sewage combined to the sea water can be determined in the same manner as above, calling $b$ the quantity of chlorine in one volume of river water and sewage combined.

# APPENDIX A.C.

*Put in by Mr. Baldwin Latham. See Q. 7787.*

TABLE showing the RESULT of EXPERIMENTS CONDUCTED by Mr. BALDWIN LATHAM, C.E., at CROYDON, upon the RATE AT WHICH RAIN FALLS, and the EXTENT to which the MAXIMUM FALL of RAIN AFFECTS the FLOW in the SEWERS of CROYDON.

### MAY 1879.

| Day of Month. | Total Quantity of Rain falling in the Day. | Maximum Quantity of Rain falling within any one Hour of the Day. | Time in which maximum Rainfall occurred. | Rate of maximum fall of Rain, if continued for 24 hours. | Time of Day when the maximum fall of Rain occurred. | Proportion of maximum flow of Sewage to mean flow caused by the maximum Rainfall at Croydon. | Time when maximum flow of Sewage occurred in Croydon Sewers. |

## APPENDIX A.F. (1).

### DETERMINATION OF THE EFFECT OF THE MIXING ACTION, IN THE WATER OF THE RIVER THAMES, BY THE AID OF THE CHLORINE TEST.

By William Pole, F.R.S., Mem. Inst. C.E.

A Tidal estuary receives, from an outfall at a certain point, a flow of sewage = S cubic feet per minute, and containing $c_2$ grains of chlorine in every cubic foot.

At various points above this the estuary receives a flow of land water, in all = L cubic feet per minute, and containing $c_1$ grains of chlorine in a cubic foot.

It may also receive, at its mouth, from the incoming tide, sea water containing $c_3$ grains of chlorine in a cubic foot.

Samples of water are taken at various points of the estuary, above and below the sewage outfall, and the quantity of chlorine in each is found by analysis. It is also found, by taking several samples at the same section, that the composition of the water is fairly homogeneous throughout the cross area of the river.

Given then the number of grains of chlorine, = C, in a cubic foot taken at any point, it is required to determine the proportion of land water, sewage, and sea water respectively at that point.

The problem must be solved separately for the lengths of the estuary below and above the sewage outlet respectively.

*First: Below the Sewage Outfall.*

Let A = the area of the river at the point where the sample is taken, in square feet. Then the quantity of water in one foot length at that section will be = A cubic feet, and the total quantity of chlorine in that quantity will be—

= A C.

Let $x$ = cubic feet of land water.
„ $y$ = „ sewage.
„ $z$ = „ sea water.
in the quantity A.

Then we have the equations—
(I.) $x+y+z = A$ and
(II.) $xc_1 + yc_2 + zc_3 = AC$.

But as the land water and the sewage have gone down together from the site of the outfall, and have become thoroughly mixed, there is every reason to conclude

App. A.F. (1). that they will retain the proportions of their origin, *i.e.*, that $\frac{x}{y} = \frac{L}{S}$ whence

$$\text{III.} \begin{cases} \frac{y}{A} = \frac{c_3 - C}{\left(\frac{L}{S} + 1\right) c_3 - \frac{L}{S} c_1 - c_2} \\ \frac{z}{A} = 1 - \left(\frac{L}{S} + 1\right) \frac{y}{A} \\ \frac{x}{A} = \frac{L}{S} \frac{y}{A} \end{cases}$$

which determine the proportions of the various elements in the mixture *at any point below the sewage outfall*. The equations may also be taken as applicable near the outfall itself.

*Secondly.—Above the Sewage Outfall.*

The formulæ given above will not apply here, because the assumption that $\frac{x}{y} = \frac{L}{S}$ will obviously not hold good *above* the outfall.

For this locality, the assumption must be reversed, and made to apply not to the land, but to the *sea* water. The sea water as it passes the sewage outfall will naturally carry a portion of the sewage with it; and since, in all parts of the river the different constituents are found uniformly mixed, it may be fairly assumed that, in all parts above the sewage outfall, the proportion of sea water and sewage water will remain the same as it was *at* the outfall; for having been once mixed there in that proportion, there is no reason why, in travelling upwards, the proportion should be altered.

Now it may be found by the equations (III.) what this proportion is at the outfall; let this be—

$$\frac{\text{Sea water}}{\text{Sewage}} = r.$$

Then for all places above the outfall—

$$\frac{z}{y} = r.$$

Substituting in equations I. and II., we get—

$$\text{IV.} \begin{cases} \frac{y}{A} = \frac{C - c_1}{c_2 + r c_3 - (r+1) c_1}. \\ \frac{x}{A} = 1 - (r+1) \frac{y}{A}. \\ \frac{z}{A} = r \frac{y}{A}. \end{cases}$$

Which determine the proportions of the various elements in the mixture at *any point above the sewage outfall*.

For simplicity of reasoning the quantities of chlorine have been assumed to be given in grains per cubic foot, but it is evident, from the form of the equations, that any other denomination may be substituted. They happen to be given in parts per 100,000 by weight, and the fixed quantities used in the calculations of this matter by the various witnesses are—

$$c_1 = 1{\cdot}7.$$
$$c_2 = 10{\cdot}.$$
$$c_3 = 1961{\cdot}.$$

Inserting these the equations become—

$$\text{(III.)} \quad \frac{y}{A} = \frac{1961 - C}{1961 \left(\frac{L}{S} + 1\right) - 1{\cdot}7 \frac{L}{S} - 10}.$$

$$\text{(IV.)} \quad \frac{y}{A} = \frac{C - 1{\cdot}7}{10 + 1961\, r - 1{\cdot}7\,(r+1)}.$$

$\frac{x}{A}$ and $\frac{z}{A}$ in both cases as before.

By these equations the following tables are calculated.

---

Approximate Composition of the Water at different points of the River Thames, as shown by the Chlorine Tests.

*(The following results are laid down graphically on the accompanying diagrams,* A.F. (2)).

I.

September 14, 1882.
Land water about 25 per cent. under the average.
Spring tide. High water.

$$\frac{L}{S} = \frac{93{,}167}{16{,}090} = 5{\cdot}79$$
$$r = 5 \text{ nearly.}$$

None of these chlorine tests happen to have been made at the time which is of the greatest importance in the inquiry, namely, in the driest weather. The inflow of fresh water on the 14th September was below the average, but it was much more than the minimum. In the absence, therefore, of any direct data, it is worth while to see if a rough estimate can be made of what the effect might be in the driest time.

The three amounts of inflow given vary considerably, and by examining the effect of the variation it may be possible to form some empirical rule by which the effect may be carried farther.

We may take as the element to be found the maximum proportion of sewage in the river at both high and low water; it is obvious that this will become greater as the inflow of water is less; and a critical examination of the nature of the increments will show that the quantities may be represented, empirically, by an expression of the following form.

Let Y = the maximum proportion of sewage in 1,000 parts of the river, and L = the inflow of fresh water; then—

$$(Y + \alpha)^2 = \beta \left( \frac{10,000,000}{L} + \gamma \right)$$

Where $\alpha$, $\beta$, and $\gamma$, are constants differing for high and low water respectively. They may be taken approximately as follows:—

For high water $\alpha = 0$; $\beta = 75$; $\gamma = -10$.

„ low „ $\alpha = 60$; $\beta = 270$; $\gamma = +10$.

The following tables show the result of this mode of estimation. App. A.F. (1).

| At High Water. | Inflow of Land water, in cubic feet per minute. | Parts of Sewage in 100 parts of River water near the Outfalls. |
|---|---|---|
| 1882. | | |
| November 30 | 522·000 | 2·5 |
| September 22 | 134·000 | 7·0 |
| September 14 | 93·167 | 8·5 |
| *In dry weather, minimum flow (Estimated)* | *48·500* | *12·0* |
| **At Low Water.** | | |
| November 30 | 522·000 | 2·8 |
| September 22 | 134·000 | 8·7 |
| September 14 | 93·167 | 11·8 |
| *In dry weather, minimum flow (Estimated)* | *48·500* | *18·0* |

According to this estimate therefore, in dry weather, at low water, no less than 18 per cent of the river near the outfalls may consist of liquid which has been discharged from the sewer. The distribution over the length of the river may easily be estimated, by the former results.

The mean rate of permanent progress of the sewage down the river at any place will be equal to the quantity of land water and sewage travelling down divided by the area of section at that place occupied by the two together at mean tide level, $= \frac{L \quad S}{x + y}$. The result for each of the days calculated is given in the following table.

| | Total sectional area, mean tide level. | Nov. 30. | Sept. 22. | Sept. 14. | Dry weather. (Estimated.) | |
|---|---|---|---|---|---|---|
| L + S in cubic feet per minute | — | 537,943 | 150,154 | 109,257 | 64,000 | |
| | | *Downward Progress in miles per diem.* | | | | |
| At the Outfalls | 50,200 | 3·1 | 1·1 | 0·85 | | 0·6 |
| At Erith | 70,475 | 2·3 | 0·91 | 0·71 | | |
| At Gravesend | 96,674 | — | 1·1 | 0·87 | | |

There appears to be some uncertainty about the values of the data $c_2$ and $c_3$. The quantity of chlorine in normal sewage has been taken here at 10 parts in 100,000, but some chemists believe it to be higher, ranging between 10 and 20. It will, however, be evident by a glance at equations III. and IV. that any variation between these limits cannot have any appreciable influence on the value of $y$; the difference, if $c_2$ were made = 20, would be less than $\frac{1}{10}$ per cent; the reason of this is, that the proportion of sewage in the water is deduced chiefly from the proportions of the sea and land water in the mixture, and not from the chlorine in the sewage, which only enters into the equation as a slight correction.

The quantity of chlorine in sea water has been taken as 1961; but it varies considerably in different places. Here again the equations will show that a moderate change in this datum will not have much effect. For example, a variation of 50 parts either way would not, in the most important case, vary the result one per cent. The important element is the quantity C (the chlorine at the point taken) and if this is correct the results given in the tables cannot be materially wrong.

The ratio $\frac{L}{S}$ is assumed to have been constant, or nearly so, for some time before the observation; but, strictly, this ratio should apply to the period when the water, at the point calculated, may be assumed to have passed the outlets.

## APPENDIX A.H.

See Q. 10, 847.

REPORT on the SUSPENDED MATTER in LONDON SEWAGE by PROFESSOR E. FRANKL AND, F.R.S.

In recent inquiries into the composition and polluting power of London sewage, scarcely any notice has been taken of the effect of rainfall upon the proportional and absolute amount of suspended matter or mud discharged from the outfalls.

Inasmuch, however, as every ·01 inch of rain augments the volume of London sewage by upwards of 14,000,000 gallons, and as all analyses point to the conclusion that the heavier the rainfall the larger the proportion of suspended matter in the sewage, it follows that any estimates based upon the dry weather flow of sewage and its chemical composition must be exceedingly incorrect; for whilst in 76 samples of dry weather sewage (even when all dry weather samples containing an abnormally large amount of suspended matter were excluded) there was on the average 23·36 grains of suspended matter; 9 samples of sewage, collected on days when the rainfall was 0·1 inch and upwards, averaged no less than 134·94 grains of suspended matter per gallon.

I have, therefore, compiled tables showing :—

1. The rainfall on every day during the years 1878 and 1879.
2. A short (official) description of the way in which rain fell on each occasion.
3. The average number of grains of suspended matter contained in a gallon of sewage discharged into the Thames :—
   (*a.*) In fair weather;
   (*b.*) In rainy weather when the daily rainfall does not exceed 0·03 inch;
   (*c.*) Ditto when the daily rainfall is above 0·03 inch, but under 0·1 inch.
   (*d.*) Ditto when the daily rainfall is 0·1 inch and over.
   Also the actual and average amounts of mineral and organic matter contained in the suspended matter in each of these cases.
4. The number of gallons of sewage entering the Thames each day in 1878 and 1879.
5. The number of tons of dry suspended matter discharged into the Thames each day, and the number of tons of wet mud to which this would be equivalent, on the supposition that 1 ton of dry suspended matter forms 3 tons of wet mud.
6. The total amount of dry and wet mud discharged into the Thames during each of the years 1878 and 1879.
7. The average percentages of organic and mineral matter in fair weather sewage, in storm sewage, and in the aggregate mud discharged in each of the two years.

These tables are appended to this Report.

Table A contains the information mentioned in paragraphs 1 and 2. It is compiled from the Meteorological Observations made at the Royal Observatory, Greenwich, under the superintendance of the Astronomer Royal, and published in the "Weekly Returns of Births, Deaths, &c.," issued by the Registrar General.

Table B shows the results of analysis, actual and average, as regards suspended matter, of 82 samples of fair-weather London sewage, of 10 samples when the rainfall did not exceed ·03 inch in 24 hours, of 2 samples when it was above ·03 inch, but under ·1 inch, and of 11 samples taken on days when the rainfall was ·1 inch and upwards. The analyses executed by Messrs. Hofmann and Witt are marked with an asterisk, and those made by Mr. Keates with an obelisk †. The unmarked analyses are my own. All the analyses are given in the Table, but such as are obviously abnormal are ruled out and excluded from the averages. This table also contains the rainfall, if any, and remarks on the weather.

Table C gives, for the years 1878 and 1879, the number of days when no rain fell, and the number under each particular depth of rain, together with the information mentioned in paragraphs Nos. 4, 5, and 6. In this table the rain is calculated as falling upon 122 square miles, and 20°/₀ is allowed for evaporation, which is probably much in excess of the truth. On the rainless days the volume of the sewage is reckoned as equal to the average daily water supply, which was 129,657,848 gallons in 1878, and 134,443,669 gallons in 1879. I have taken, however, the round numbers, 130,000,000 and 134,000,000, in the Table. On the rainy days these volumes are added to the rainfall minus 20°/₀, to find the total volume of sewage. This daily sewage rate is given in the fourth column of the table, whilst the fifth column records the number of tons of dry suspended matter contained in this volume of sewage, multiplied by the number of days (given in the first column) during which this rate of flow prevailed. The dry suspended matter is converted into wet mud, in this table, by multiplying it by 3. This multiplier is probably rather too high, and I have therefore given separately the aggregate weight of wet mud discharged in each of the two years, on the assumption that it contains only 60°/₀ of water, which is the proportion actually found by Dr. Tidy in the mud deposits of the tidal Thames.

Table D shows the aggregate number of tons of dry organic, mineral, and total suspended matter in the four average varieties of sewage discharged into the Thames in each of the years 1878 and 1879, and defined in table B. The numbers in this table show strikingly how enormously the proportion of mineral matter in the sewage mud is raised in wet weather; for whilst the percentage in dry-weather mud is only 40·41, it rises to 44·16 with a rainfall not exceeding ·03 inch, to 65·38 when the rainfall is above ·03 but under ·1, and to no less than 75·16, when the rainfall is above ·1 inch.

In this table the wet mud is assumed to contain 60°/₀ of water.

E. FRANKLAND.

### TABLE A.

RAINFALL and WEATHER OBSERVATIONS for the Years 1878 and 1879.

| 1878. | Rainfall. | Remarks. |
|---|---|---|
| Jan. 1 | ·00 inch. | |
| „ 2 | ·02 „ | Overcast; thin rain and fog. |
| „ 3 | ·05 „ | Fine and partially cloudy in morning; rain fell occasionally in afternoon and evening. |
| „ 4 | ·22 „ | Overcast; frequent rain. |
| „ 5 | ·02 „ | „ „ „ |
| „ 6 | ·01 „ | Generally overcast; a little rain fell in the early morning hours. |
| „ 7 | ·01 „ | Partially cloudy; fine throughout morning; slight rain in afternon. |
| „ 8 to 14 | ·00 „ | |
| „ 15 | ·02 „ | Overcast generally; rain in morning. |
| „ 16 to 22 | ·00 „ | |
| „ 23 | ·06 „ | Heavy squall of wind and rain in early morning; showery at times. |
| „ 24 | ·00 „ | |
| „ 25 | ·05 „ | Variable; occasional showers of rain and snow. |
| „ 26 | ·00 „ | |
| „ 27 | ·02 „ | Overcast; occasional rain. |
| „ 28 | ·39 „ | „ with heavy rain till afternoon. |
| „ 29 to 31 | ·00 „ | |
| Feb. 1 | ·00 „ | |
| „ 2 | ·01 „ | Overcast; occasional thin rain. |
| „ 3 | ·00 „ | |
| „ 4 | ·03 „ | „ rain in morning. |
| „ 5 | ·01 „ | „ rain fell in the early morning. |
| „ 6 to 8 | ·00 „ | |
| „ 9 | ·01 „ | „ rain in morning. |
| „ 10 | ·16 „ | „ rain and fog. |
| „ 11 | ·00 „ | |
| „ 12 | ·03 „ | A fine day; overcast with rain after 11 p.m. |
| „ 13 | ·08 „ | Overcast, with slight exceptions; rain fell during the morning. |
| „ 14 | ·51 „ | Overcast, rain fell throughout the morning until p.m. |
| „ 15 | ·02 „ | Cloudy hin rain fell in the evening. |
| „ 16 & 17 | ·00 „ | |
| „ 18 | ·03 „ | Cloudy in morning, and a showery rain fell between 5 and 6 a.m. |
| „ 19 to 26 | ·00 „ | |
| „ 27 | ·19 „ | Overcast; rain fell throughout the afternoon and evening. |
| „ 28 | ·02 „ | Overcast; occasional rain. |
| March 1 | ·11 „ | Overcast; frequent rain. |
| „ 2 | ·02 „ | Rain fell in the early morning hours. |
| „ 3 to 9 | ·00 „ | |
| „ 10 | ·08 „ | Overcast; gloomy and rainy in the morning; fine in the afternoon. |
| „ 11 | ·00 „ | |
| „ 12 | ·01 „ | Cloudy, with slight rain in morning. |
| „ 13 to 23 | ·00 „ | |

Rainfall and Weather Observations for the Years 1878 and 1879—(*continued*).

| 1878. | Rainfall. | Remarks. |
|---|---|---|
| March 24 - | ·02 inch. | A little snow fell in early morning hours; fine till 4 p.m.; snow fell thickly till 5.30 p.m. |
| „ 25 - | ·01 „ | Snow fell in the morning, with occasional rain in the afternoon. |
| „ 26 - | ·00 „ | |
| „ 27 - | ·01 „ | Snow fell in the morning. |
| „ 28 - | ·21 „ | Overcast generally; rain and snow fell in the evening. |
| „ 29 - | ·39 „ | Overcast; snow fell thickly throughout the morning. |
| „ 30 - | ·07 „ | Cloudy; snow and rain fell occasionally. |
| „ 31 - | ·13 „ | Overcast, with rain and snow in afternoon and evening. |
| April 1 - | ·01 „ | Snow fell in the early morning hours; slight showers in the afternoon. |
| „ 2 - | ·01 „ | Partially cloudy till evening, with showers in the afternoon. |
| „ 3 - | ·17 „ | Overcast, with rain till evening. |
| „ 4 - | ·00 „ | |
| „ 5 - | ·06 „ | Partially cloudy till evening, with showers of rain accompanied by thunder and lightning. |
| „ 6 to 9 | ·00 „ | |
| „ 10 - | ·31 „ | Generally cloudy; rain commenced falling at 5 p.m., and was still falling at midnight. |
| „ 11 - | 2·51 „ | Rain fell heavily throughout the morning and until 1.40 p.m., having fallen continuously for nearly 21 hours |
| „ 12 - | ·00 „ | |
| „ 13 - | ·03 „ | Partially cloudy during morning; overcast, with rain in afternoon and evening. |
| „ 14 & 15 | ·00 „ | |
| „ 16 - | ·12 „ | Overcast; frequent rain; very gloomy in afternoon. |
| „ 17 - | ·16 „ | Cloudy; frequent showers; lightning and thunder in afternoon. |
| „ 18 - | ·00 „ | |
| „ 19 - | ·02 „ | Overcast, with rain in morning; fine and partially cloudy during the day; showery at night. |
| „ 20 - | ·43 „ | Overcast, with continuous rain from early morning until afternoon; fine afterwards. |
| „ 21 - | ·09 „ | Fine and partially cloudy till evening; overcast, with heavy rain at night. |
| „ 22 & 23 | ·00 „ | |
| „ 24 - | ·11 „ | Overcast, with frequent rain till afternoon, fine afterwards. |
| „ 25 to 28 | ·00 „ | |
| „ 29 - | ·08 „ | Rain fell throughout the afternoon and evening. |
| „ 30 - | ·20 „ | Rain fell frequently during the morning. |
| May 1 - | ·38 „ | Showery in morning; fine but cloudy in afternoon; overcast with rain at night. |
| „ 2 to 5 | ·00 „ | |
| „ 6 - | ·03 „ | Generally cloudy; rain fell at night. |
| „ 7 - | 1·52 „ | Rain fell very heavily from 5.33 p.m. to 7.30 p.m.; 1 inch rain between 6 and 6.50 p.m. |
| „ 8 - | ·30 „ | Rain fell all the morning until about 9.30 a.m.; slight showers fell till noon. |
| „ 9 - | ·02 „ | Rain fell at night. |
| „ 10 - | ·18 „ | Fine day; lightning at night; rain fell heavily between 10 p.m. and midnight. |
| „ 11 - | ·05 „ | Rain in the morning. |
| „ 12 - | ·00 „ | |
| „ 13 - | ·14 „ | Heavy rain fell in morning. |
| „ 14 - | ·02 „ | Cloudy; showery. |
| „ 15 - | ·19 „ | „ „ heavy rain at night. |
| „ 16 - | ·03 „ | Generally cloudy; rain throughout afternoon and evening. |
| „ 17 - | ·00 „ | |
| „ 18 - | ·25 „ | Frequent heavy showers of rain with thunder and lightning in morning. |
| „ 19 - | ·00 „ | |
| „ 20 - | ·22 „ | Cloudy; frequent rain. |
| „ 21 - | ·06 „ | „ showery. |
| „ 22 - | ·00 „ | |
| „ 23 - | ·32 „ | Cloudy; rain fell heavily in the morning. |
| „ 24 - | ·20 „ | Generally cloudy; rain fell frequently in afternoon and evening. |
| „ 25 - | ·01 „ | Occasional slight showers. |
| „ 26 - | ·07 „ | Showery. |
| „ 27 - | ·01 „ | Occasional light showers. |
| „ 28 - | ·28 „ | Overcast generally; rain at night. |
| „ 29 - | ·04 „ | „ rain fell in morning. |
| „ 30 - | ·00 „ | |
| „ 31 - | ·01 „ | A little rain at night. |
| June 1 - | ·00 „ | |
| „ 2 - | ·00 „ | |
| „ 3 - | ·03 „ | Rain fell in early morning. |
| „ 4 - | ·30 „ | Variable; rain fell very heavily in the early morning, and occasional showers fell in the afternoon and evening. |
| „ 5 - | ·07 „ | Overcast and showery till evening. |
| „ 6 & 7 | ·00 „ | |
| „ 8 - | ·40 „ | Cloudy; thunderstorm between 4 p.m. and 5 p.m. |
| „ 9 - | ·01 „ | Cloudy and showery in morning; fine afterwards. |
| „ 10 - | ·07 „ | Partially cloudy; showery; thunder in afternoon. |
| „ 11 - | ·02 „ | Showery till evening. |
| „ 12 - | ·12 „ | Occasional showers of rain. |
| „ 13 - | 1·05 „ | None in the morning; very heavy in the afternoon. |
| „ 14 - | ·01 „ | A little rain in early morning. |
| „ 15 - | ·00 „ | |
| „ 16 - | ·98 „ | Rain fell heavily in early morning hours; heavy rain fell also in evening. |
| „ 17 - | ·01 „ | Showery in afternoon. |
| „ 18 to 22 | ·00 „ | |
| „ 23 - | ·61 „ | Violent thunderstorm in afternoon. |
| „ 24 to 29 | ·00 „ | |
| „ 30 - | ·89 „ | Frequent rain with thunder during the day. |

Rainfall and Weather Observations for the Years 1878 and 1879—(*continued*).

App. A.H.

| 1878. | Rainfall. | Remarks. |
|---|---|---|
| July 1 - | ·00 inch. | |
| „ 2 - | ·03 „ | Occasional rain in morning. |
| „ 3 - | ·02 „ | „ „ and afternoon. |
| „ 4 to 8 | ·00 „ | |
| „ 9 - | ·02 „ | Showery in evening. |
| „ 10 to 21 | ·00 „ | |
| „ 22 - | ·03 „ | Shower of rain in afternoon. |
| „ 23 - | ·00 „ | |
| „ 24 - | ·04 „ | |
| „ 25 - | ·07 „ | Showery. |
| „ 26 - | ·07 „ | „ |
| „ 27 & 28 | ·00 „ | |
| „ 29 - | ·01 „ | Showery in afternoon. |
| „ 30 - | ·01 „ | Midday showery. |
| „ 31 - | ·00 „ | |
| August 1 & 2 | ·00 „ | |
| „ 3 - | ·23 „ | Slight rain in early morning; thunderstorm with rain before noon. |
| „ 4 - | 1·23 „ | Fine till noon; thunderstorms. |
| „ 5 - | ·39 „ | Showery in early morning; fine till evening; violent rain and lightning at night. |
| „ 6 - | ·14 „ | Rain with lightning in early morning; slight shower at night. |
| „ 7 to 9 | ·00 „ | |
| „ 10 - | ·46 „ | Overcast generally; frequent rain. |
| „ 11 - | ·00 „ | |
| „ 12 - | ·16 „ | Variable; showery; lightning; and thunder in the afternoon. |
| „ 13 - | ·12 „ | Overcast generally. |
| „ 14 - | ·23 „ | Rain fell heavily in early morning hours; generally fine after; shower of rain in evening |
| „ 15 - | ·11 „ | Fine and partially cloudy till evening; overcast afterwards. |
| „ 16 - | ·45 „ | Variable; frequent showers. |
| „ 17 - | ·01 „ | A light shower of rain fell about 6 p.m. otherwise fine. |
| „ 18 to 21 | ·00 „ | |
| „ 22 - | ·10 „ | Rain fell at night. |
| „ 23 - | ·83 „ | Frequent heavy showers of rain accompanied by thunder till evening. |
| „ 24 - | ·28 „ | Frequent heavy showers of rain with lightning and thunder. |
| „ 25 - | ·01 „ | A little rain fell in early morning. |
| „ 26 - | ·00 „ | |
| „ 27 - | ·08 „ | Cloudy and showery in morning. |
| „ 28 - | ·00 „ | |
| „ 29 - | ·32 „ | Cloudy; frequent showers of rain with thunder. |
| „ 30 - | ·42 „ | A gale of wind in morning; variable and showery with lightning and thunder during day. |
| „ 31 - | ·32 „ | Showers of rain; thunder in afternoon. |
| Sept. 1 to 7 | ·00 „ | |
| „ 8 - | ·01 „ | Fine till afternoon; overcast, with occasional thin rain afterwards. |
| „ 9 to 11 | ·00 „ | |
| „ 12 - | ·01 „ | A shower fell in afternoon. |
| „ 13 & 14 | ·00 „ | |
| „ 15 - | ·12 „ | Fine day; overcast with heavy rain at night. |
| „ 16 & 17 | ·00 „ | |
| „ 18 - | ·23 „ | Frequent rain till afternoon. |
| „ 19 - | ·00 „ | |
| „ 20 - | ·14 „ | Heavy rain in early morning; cloudy all day; sharp shower of rain and hail fell in afternoon; cloudless at night. |
| „ 21 - | ·00 „ | |
| „ 22 - | ·01 „ | Slight rain in morning; then rain in evening. |
| „ 23 - | ·13 „ | Rain in early morning; fine during day; evening cloudless, heavy dew. |
| „ 24 - | ·00 „ | |
| „ 25 - | ·05 „ | Occasional thin rain. |
| „ 26 to 29 | ·00 „ | |
| „ 30 - | ·12 „ | Rain fell in early morning hours; fine till afternoon; overcast afterwards. |
| Oct. 1 - | ·01 „ | Showery at night. |
| „ 2 to 5 | ·00 „ | |
| „ 6 - | ·04 „ | Rain fell in the evening. |
| „ 7 - | ·20 „ | Rain fell heavy in early morning hours; fine throughout day. |
| „ 8 - | ·06 „ | Rain fell in early morning hours; fine during day. |
| „ 9 - | ·07 „ | Showery and windy. |
| „ 10 - | ·17 „ | Showery till afternoon; fine afterwards. |
| „ 11 to 21 | ·00 „ | |
| „ 22 - | ·20 „ | Overcast with heavy rain in morning; shower of hail and rain in afternoon. |
| „ 23 - | ·01 „ | Showery in afternoon. |
| „ 24 - | ·32 „ | Overcast with rain throughout morning; fine in afternoon and evening. |
| „ 25 - | ·00 „ | |
| „ 26 - | ·45 „ | Cloudy and showery till evening. |
| „ 27 - | ·00 „ | |
| „ 28 - | ·02 „ | Occasional showers of rain and hail. |
| „ 29 - | ·00 „ | |
| „ 30 - | ·08 „ | Snow and rain fell in the morning |
| „ 31 - | ·03 „ | Overcast with rain in evening. |
| Nov. 1 - | ·01 „ | Overcast with rain in the morning; fine afternoon. |
| „ 2 to 7 | ·00 „ | |
| „ 8 - | ·10 „ | Showery. |
| „ 9 - | ·00 „ | |
| „ 10 - | ·79 „ | Overcast with frequent heavy rain till evening; fine night. |
| „ 11 - | ·04 „ | Shower of hail and granular snow fell shortly before 2 p.m.; thin rain at night. |
| „ 12 - | ·00 „ | |
| „ 13 - | ·03 „ | Occasional rain. |
| „ 14 - | ·44 „ | Frequent rain. |

Rainfall and Weather Observations for the Years 1878 and 1879—(*continued*).

| 1879. | Rainfall. | Remarks. |
|---|---|---|
| July 24 - | ·02 inch. | Showery in morning. |
| „ 25 - | ·00 „ | |
| „ 26 - | ·01 „ | A few light showers of rain. |
| „ 27 to 30 | ·00 „ | |
| „ 31 - | ·10 „ | Continual rain till afternoon. |
| August 1 - | ·16 „ | Continual rain in early morning. |
| „ 2 - | ·00 „ | |
| „ 3 - | ·09 „ | Slight thunderstorm a.m. |
| „ 4 - | ·01 „ | Showery in morning. |
| „ 5 - | ·09 „ | Fine, generally cloudy. |
| „ 6 - | ·21 „ | Showery; thunder about noon. |
| „ 7 - | ·10 „ | „ in afternoon an evening. |
| „ 8 - | ·01 „ | A little rain at night. |
| „ 9 to 15 | ·00 „ | |
| „ 16 - | ·03 „ | Showery. |
| „ 17 - | ·51 „ | Frequent rain. |
| „ 18 - | ·19 „ | „ „ in morning, |
| „ 19 - | ·38 „ | „ „ |
| „ 20 - | ·56 „ | Heavy rain all morning; some showers after. |
| „ 21 - | ·20 „ | Frequent showers; in afternoon rain with thunder. |
| „ 22 - | ·02 „ | A shower fell about 10 a.m. |
| „ 23 - | 1·17 „ | Heavy rain till afternoon; showers in evening. |
| „ 24 - | ·00 „ | |
| „ 25 - | ·16 „ | Frequent showers in morning. |
| „ 26 - | ·39 „ | Fine morning; showery after. |
| „ 27 - | ·22 „ | Rain fell frequently. |
| „ 28 - | ·48 „ | Heavy rain from 6 a.m. to 2 p.m. |
| „ 29 - | ·16 „ | Showery in afternoon and evening. |
| „ 30 & 31 | ·00 „ | |
| Sept. 1 to 4 | ·00 „ | |
| „ 5 - | ·01 „ | A little rain fell in the morning. |
| „ 6 - | ·01 „ | Slight rain about 1 p.m. |
| „ 7 - | ·01 „ | Showery in afternoon. |
| „ 8 - | ·06 „ | Heavy shower fell between 10 and 10.30 a.m. |
| „ 9 - | ·17 „ | Showery. |
| „ 10 & 11 | ·00 „ | |
| „ 12 - | ·12 „ | Showery at night. |
| „ 13 - | ·36 „ | Rain in afternoon. |
| „ 14 - | ·19 „ | Rain in morning. |
| „ 15 & 16 | ·00 „ | |
| „ 17 - | ·07 „ | Occasional rain. |
| „ 18 - | ·03 „ | A little rain. |
| „ 19 to 22 | ·00 „ | |
| „ 23 - | ·75 „ | Frequent rain. |
| „ 24 - | ·71 „ | Heavy rain in morning; showery after. |
| „ 25 to 27 | ·00 „ | |
| „ 28 - | ·19 „ | Heavy rain at night. |
| „ 29 - | ·16 „ | Heavy rain in early morning hours. |
| „ 30 - | ·00 „ | |
| Oct. 1 - | ·20 „ | Heavy rain in morning. |
| „ 2 - | ·02 „ | Showery between 9 a.m. and 1 p.m. |
| „ 3 to 13 | ·00 „ | |
| „ 14 - | ·01 „ | A little rain fell at night. |
| „ 15 to 17 | ·00 „ | |
| „ 18 - | ·01 „ | Little rain at night. |
| „ 19 - | ·16 „ | Frequent rain. |
| „ 20 - | ·01 „ | A shower fell between 1 p.m. and 2 p.m. |
| „ 21 - | ·00 „ | |
| „ 22 - | ·02 „ | Average for 24 hours:—Foggy in morning; overcast, with occasional *misty rain* during day. |
| „ 23 - | ·01 „ | Thin rain at night. |
| „ 24 - | ·07 „ | Occasional rain in afternoon and evening. |
| „ 25 - | ·21 „ | Showery in morning. |
| „ 26 - | ·01 „ | Showery from 4 p.m. till evening. |
| „ 27 & 28 | ·00 „ | |
| „ 29 - | ·04 „ | Thin rain. |
| „ 30 & 31 | ·00 „ | |
| Nov. 1 - | ·01 „ | Occasional thin rain. |
| „ 2 - | ·00 „ | |
| „ 3 - | ·01 „ | Occasional thin rain. |
| „ 4 to 9 | ·00 „ | |
| „ 10 - | ·01 „ | Occasional thin rain. |
| „ 11 - | ·01 „ | Shower of rain fell about 5 p.m. |
| „ 12 to 18 | ·00 „ | |
| „ 19 - | ·01 „ | Thin rain in morning. |
| „ 20 - | ·15 „ | Frequent snow. |
| „ 21 - | ·32 „ | „ „ |
| „ 22 - | ·15 „ | Snow in morning. |
| „ 23 - | ·00 „ | |
| „ 24 - | ·12 „ | Fog in morning, rain at night. |
| „ 25 - | ·04 „ | After 4 p.m. rain, frozen rain and snow occasionally fell. |
| „ 26 - | ·02 „ | Occasional snow. |
| „ 27 - | ·01 „ | Little rain and snow at night. |
| „ 28 to 30 | ·00 „ | |
| Dec. 1 - | ·04 „ | Snow fell frequently. |
| „ 2 to 4 | ·00 „ | |
| „ 5 - | ·08 „ | Fog in morning; snow fell now and then in afternoon and evening, heavily at night. |
| „ 6 & 7 | ·00 „ | |
| „ 8 - | ·03 „ | Snow fell in morning. |
| „ 9 - | ·01 „ | Snow and sleet at night. |
| „ 10 - | ·01 „ | Little thin rain in forenoon. |
| „ 11 to 18 | ·00 „ | |
| „ 19 - | ·01 „ | Thin rain fell in afternoon and evening. |
| „ 20 & 21 | ·00 „ | |
| „ 22 - | ·03 „ | Thin rain till afternoon. |
| „ 23 to 27 | ·00 „ | |
| „ 28 - | ·03 „ | Thin rain in morning. |
| „ 29 - | ·00 „ | |
| „ 30 - | ·21 „ | Frequent heavy showers of rain at times mingled with hail and between 1 and 1.30 p.m. lightning and thunder. |
| „ 31 - | ·19 „ | Frequent rain. |
| 1880. | | |
| Jan. 1 - | ·01 „ | Occasional rain. |
| „ 2 to 6 | ·00 „ | A little rain between 9 and 10 a.m. on the 2nd. |

App. A.J.

# APPENDIX A.J.

## Extracts from Documents in the possession of the Erith Local Board.

*Erith Drainage.*

3, Whitehall Place,
London, S.W.,
17th September 1877.

Gentlemen,

In accordance with your clerk's letter of the 23d August, requesting me to report upon the present state of the drainage in the parish of Erith, I have had the whole of the district carefully surveyed, and have annexed to this Report a schedule of details obtained from the most reliable information I could get, which will show you how the various streets and houses are at present drained. Underlined in red are those which appear to be in the worst condition.

Accompanying this Report is a plan showing how I have subdivided the four districts as requested by you, and on this the blue lines show the existing sewers in Erith, and the red spots indicate the places underlined in the accompanying schedule.

From these details you will perceive that at present out of the whole of your district the sewage is only carried through a system of sewers in Erith proper, and these discharge into the river. In the other districts, cesspools of various depths have been universally used, and in some cottages which have recently been supplied by the Kent Waterworks Company, the old wells down to the chalk have been covered over and converted into cesspools. I need scarcely say, that this state of things requires immediate attention, and I feel confident that nothing but a general system of sewage for the whole district will meet the requirements of the Local Government Board.

A comprehensive plan should be at once prepared, and the necessary steps taken to obtain the sanction of the central authority to its being carried out.

I am, &c.
(Signed) Edward Easton.

To the Erith
Local Board of Health,
Erith, Kent.

---

*State of Sewers in Erith.*

Through Wheatley Terrace there is a large brick drain. This discharges into the river opposite the gardens through an iron pipe having a flap valve on the river bank. This drain is said to be between 3′ 6″ and 4′ 6″ high and 2′ 4″ wide.

This is joined in Appold Street by a brick sewer commencing on the Wheatley Terrace side of the tramway. This drain said to be 2′ 4″. A few houses are drained above the railway branch through a six-inch pipe drain which is carried under the line.

The brick sewer is carried up from Wheatley Terrace the same size to crossing of High Street and Pier Road, and then continued up to opposite "Prince of Wales" public-house in Avenue Road. A pipe goes up High Street from the Pier Road to opposite Messrs. Catchpole's Brewery. The large sewer is reported to be in good condition. Opposite the "Prince of Wales" it receives a drain from the Avenue Road, and another from the backs of Crayford Road. Another branch is also taken up Queen Street and is carried up Queen's Road, and joins the sewer from Bexley Road in Pier Road, and another branch in Queen's Road is taken the other way to Avenue Road, Albert Villas, in the Queen's Road are drained at the back into Avenue Road, and then into brick sewer.

In Pier Road an iron pipe is taken up over the railway bridge, and continued by an earthenware pipe to the top of the villas.

This joins the large sewer at the corner of Pier Road and High Street.

Another branch joins the sewer opposite Mr. Stones, in Pier Road, coming from Custom House Cottages and the back of Collrook Street.

In Pier Road and High Street several of the houses are drained through the front, and have, as a rule, separate drains. This is only exceeded in case of three and four houses belonging to one owner. The only ventilation to large sewer is near the public hall. It used to be ventilated, but these have been stopped up some time since.

*Outfall by Flour Mill.*

This is said to be a private drain, draining on its way down several cottages, and is reported to have been well put in.

This sewer goes through Mr. Steers' stables up at the back (right hand) of Crown Street, 9-inch pipes are laid all the way; it is trapped by a syphon where it turns off the road. There are five houses in High Street drained into this at the bottom.

At the bottom of Crown Street a pipe joins this sewer, draining all the houses on the left hand, going up to No. 18. A small drain is then carried above this to drain the "Rose and Crown." This sewer goes up the back, and comes through the opening by R. Austin's shop.

*Outfall from Bexley Road.*

This sewer is laid from the police station in Bexley Road through High Street, and discharges into the river opposite the Causeway through a brick sewer. At the bottom of the Bexley Road it receives two drains, one from the back of the houses on the left going up, and another from a small yard on the right. From the information obtained, it appears these two branches are too small to properly carry off the drainage. At the upper end a small line of pipes is laid across the road to drain the "King's Arms" public house.

---

To the Erith Urban Sanitary Authority.

Pier Road, Erith,
16th January 1878.

Gentlemen,

In presenting my first annual Report to you, it is with a feeling of great joy that I congratulate you upon the fact of there not having been a single death from any infectious disease during the last six months, and further, that during the year there has been a complete absence of any epidemic.

It is true there were a few isolated cases of small-pox imported into the district at the commencement of the year, but prompt action was taken, and the disease did not spread.

The cases of typhoid fever that occurred in Crown Street and Back Lane at the spring were examined into, and the wells either cleared out or closed, and since then there have been only a few cases reported to me, and these of a mild character.

I would here suggest the advisability of having all wells closed, and enforcing the company to lay on a constant supply of water to every house, as nearly all the wells in the village are influenced by the tide of the river, and many must be more or less affected by the river water, which, as you know, is greatly impregnated with sewage.

As I know you have given instructions for a complete system of drainage to be planned for the district, it is not worth while to trouble you with many details with which you are already acquainted; but I would, however, have you bear in mind that it would be as well if you could at the same time bring into your system the whole of the North End in the parish of Crayford, and I think the Local Government Board would, if you asked them, give you power to extend your boundary as to take in that portion of Crayford parish which really forms a part of Erith town.

The cases of small-pox above alluded to were imported into the parish from Crayford or London in the first place.

I have from time to time reported to you upon different portions of the parish which in every case has received prompt attention.

The well behind the "Standard" public house, which is situated far too near the cesspool and urinal, and which I reported to you a short time since, your inspector tells me the landlord declines to close without the water is analysed, I directed the surveyor to ask you to have this done.

The drainage down Manor Road, to which attention has constantly been drawn, you have informed me is postponed awaiting the report upon the general scheme of drainage.

You will remember in the Summer some of your board attended at Dartford to consult with the guardians

respecting the advisability of erecting a joint hospital for infectious fevers, &c., but nothing came of it. I would strongly urge you, however, to erect one for yourselves, or get Crayford and Bexley to join you. This is more forcibly impressed upon me as there is a case of small-pox at present in the village which I have no power to enforce to go into the Union Infirmary, and who, therefore, is now being treated at her own home.

A special report upon this case will be before you.

The death rate for the year has been remarkably low, as you will see by perusing the accompanying table, only averaging 13·1 per 1,000, calculating for increase of population.

Believe me, &c.

(Signed) Fredk. B. Jessett, F.R.C.S.E.,
Medical Officer of Health.

---

*Annual Report for the Year ending 31st December 1878.*

To the Urban Sanitary Authority, Erith.

Pier Road, Erith,
29th January 1879.

Gentlemen,

The health of the parish has been even better this year than it was last, as you will see by perusing the subjoined tabular reports.

With regard to the influence affecting or threatening to affect injuriously the health of the parish, I would in the first place point out those that actually do affect the public health injuriously, and then allude to those influences which threaten to affect it.

Firstly, then, a great part of the parish is either very imperfectly drained, or has no drainage at all, I allude in the first place to that property that is drained into the general sewer and has no ventilating shafts, and the closets and sinks of which are very indifferently trapped. Among this property may be classed a great part of Queen's Road, Crayford Road, and the High Street; that part of Queen's Road known as Stonleigh Villas, as my report on that property showed was in a most fearful condition, the drain in many instances actually being ventilated by means of a waste water pipe directly into the houses, the result being a fatal case of typhoid fever. This state of things is, however, remedied, or in course of being so.

In Crayford Road the drainage, although going into the main sewer, is very imperfect, and there is a complete absence of ventilation, however, none of the closets being furnished with cisterns, there is no water to flush the drains, excepting what the people throw down, the consequence being that often the drain gets clogged.

The sinks in nearly all this property are very bad, being furnished merely with bell-traps, which in many instances are either broken or otherwise out of order.

Next with regard to that property that is not drained at all or are merely drained into very indifferent cesspits.

This represents a very large portion of the property, viz.: Belvedere Abbey Wood, Northumberland Heath, Manor Road, Erith, Lesney Park, West Street, and South Street, Erith.

In Belvedere the drainage is very bad. Many of the gardens at the rear of the houses having several cesspits in them, so much so, that in some of the best shop property, I am told, it is difficult to sink any more.

This is a state of things that must be remedied.

Abbey Wood in cases is nearly as bad, but not being so densely populated, the same ill effect is not so likely to result.

Northumberland Heath is rearly worse than either, as the population here is very poor and densely populated. The different districts named in Erith are all, with few exception, equally bad.

The only remedy for these evils is a thorough and complete system of drainage. This, I am glad to find you studying; the plans for draining the parish prepared for you by Mr. Easton is likely shortly to be very effectually carried out.

So much for the drainage; now for the water supply. This is most important, more especially as I have shown so much property is only drained into cesspits. There are still a great number of houses and cottages not supplied with water from the company, the occupants having to get the water for drinking and other purposes from wells in many cases in close contiguity with some cesspit or with some pit which has been closed. This is the case in the Pier Road (Francis Cottages), Park Spring Place, High Street, some parts of Bexley Road, formerly known as Back Lane, Northumberland Heath, and Abbey Wood.

Belvedere is, I think, nearly all supplied with the company's water.

Now, of course, water supply from the main is very likely to, and in point of fact does, very quickly fill up cesspits, and they have therefore to be constantly emptied.

But on the other hand, if wells are in close vicinity to cesspits, they run the great risk of becoming polluted with sewage. It therefore becomes a choice of evils of which it is your duty to choose the least, which is, of course, that which runs the least risk of affecting injuriously the health of the occupier, viz., a good supply of water from the main.

Having alluded somewhat fully to this part, let me briefly notice that which threatened to prove injurious to the public health.

I think nobody who has noticed the large quantity of ice washed into the shore in Erith Reach about Church Hole, the ballast wharves, the crown quay, and the pier, cannot but be struck with the very strong set of tide running down from London into Erith, the result of which must be, I think, to wash a large quantity of the sewage sent out at Barking and Crossness outfalls into Erith, and depositing it upon our banks.

The parish has been peculiarly free from all epidemic of infectious disease, as although there have been some cases of scarlet fever, the disease has not spread at all, in fact, as will be seen by the tabular report, there have been only eight deaths during the whole year. One family in which two deaths occurred undoubtedly contracted the disease in London. In every case prompt measures have been adopted, and to this I attribute the limited number of cases.

*Offensive Trades.*

There are still some offensive processes of trade going on in Erith marshes, at the artificial manure works, and glue works, the owners of which do not take proper precautions to consume the smells emitted in the manufacture of their articles. This, in the coming Session of Parliament, will be dealt with, and a Bill introduced which, if passed, will enable you to deal with these nuisances.

*Sanitary Improvements.*

During the year at my suggestion a number of wells have been closed which were found polluted with sewerage, and I hope in the course of time to get rid of all the wells situated in the town.

Picardy Street has been much improved in every way, the drainage however, like the rest of Belvedere, cannot be properly undertaken until the whole parish is thoroughly drained.

Stoneleigh Villas have been thoroughly inspected, and the drainage is being now put into a proper condition. When completed I shall make another survey of this property and report thereon.

During the year I have visited, with many members of your Board, the Hertford Sewage Works, with the view of reporting thereon as to the advisability of our adopting the same system as is carried out at Hertford. I sent in a full report of this to your board.

Subsequently I visited Aylesbury and inspected the "A.B.C." system with the same object.

A great part of the drainage that I recommended you to do, and which you investigated, have been postponed, awaiting the decision as to the best mode of draining the whole parish.

I think the board may congratulate themselves on the excessively low death rate of the parish which would compare most favourably with any other town in England, and as this is the case now when we are bound to admit our drainage, &c. is far from perfect, may we not fairly hope to attain to a still higher degree of perfection when the admirable drainage scheme sketched out by Mr. Easton is carried out.

There have been 142 deaths in the parish during the year; of these nearly half have been either over 60 years of age or under 1.

This gives, allowing for increase of population, the extraordinary low death rate of 11·83 per 1,000.

Now it will be no doubt intering to you to know approximately the death of the different districts, viz., Erith proper, Belvedere, and Northumberland Heath.

At the last census, at Belvedere and Abbey Wood, there were 623 houses, with a population of 3,004 people. Northumberland Heath 153 houses, with population of

App. A.J.

675, and Erith proper 911 houses, with a population of 4,294 inhabitants. The marshes and Crossness having 56 houses and 316 population.

This is an abstract of the census of 1871. Let us see then how the number of deaths stand in relation to the population of each district, we shall find it thus:

| | Population in 1871. | Deaths. | Death rate. |
|---|---|---|---|
| Erith - - - - | 4,294 | 68 | 16·07 |
| Belvedere - - - - | 3,004 | 52 | 17·3 |
| Northumberland Heath - - | 675 | 12 | 17·7 |
| Marshes - - - - | 316 | 3 | — |
| Violence - - - - | — | 7 | — |

This being the population at the last census, and as Erith proper has increased considerably more since then than either Belvedere or Northumberland Heath it follows if one could get at the exact population now that the death rate of Erith has been considerably lower than either of the other districts, but even taking the rate at the last known population it is still remarkably low.

Believe me, &c.,

T. Parish, Esq., Clerk to the Board. F. B. Jessett.

---

To the Erith Sanitary Authority.

Pier Road, Erith, Kent,

Gentlemen, October 27th, 1879.

I visited with your Inspector of Nuisances the different manufactories on the river bank situated in your parish.

The building furthest from Erith was empty but had been used recently for experiments.

Next to this are Bevington's Artifical Manure Works, the manure being the product of boiling scutch by steam at a high pressure with sulphuric acid this afterwards being run into open vats, and when sufficiently dry being thoroughly dried over long brick kilns.

Precautions appear to be taken here for the prevention of escape of the vapour while the scutch is being boiled, but the smell from the evaporation when run into the vats is very offensive, as also is the smell while the product is being dried over the kilns.

More care should be taken here, in the first place the boiled liquid should not be allowed to run out of the boilers until quite cold, and then when run into the vats I think there should be good covering of lime thrown over the whole.

The drying over the kilns should be avoided as much as possible and certainly not used until the product is very much drier than is the case at these works, I believe this drying is detrimental to the commercial value of the manure as large quantities of ammonia are driven off by the heat.

Collins, late Brown, Manure and Glue Works are contiguous to the last named factory being separated by a wide and very offensive ditch filled with filth, and the drainage from certain cottages a short distance off. This ditch should be filled in and some large glazed earthenware pipes placed there to carry off the drainage.

Collin's works were not working at our visit, the boiler being out of order, but the whole building was very dirty. Their business appears to be to extract glue from old horses hoofs, hide, shedding, &c. and then from the scutch to treat it with oil of vitrol, and boil by steam in closed boilers, then to run the product under cover to dry. They do not use any kilns, and the manager informed me that they treat the boiled scutch after skimming off the fat with saltpetre and sugar scum to prevent the smell.

It did not seem to have the desired effect, however, as the smell was very bad.

Here there were flues connected with the boilers and run into the main shaft. This appeared to be very bad as the steam, of necessity, was carried from the boiling scutch up the flues to the shaft and then wafted whither the wind took it. These flues should be done away with and the scutch boiled under high pressure as at Bevington's.

More cleanness should be observed at this factory.

The building has been erected some three years.

Next to Collin's are two very large factories in course of erection, the first called the French Alum Company and the next the Metal and Chemical Company for making paint.

The alum in the first washing extracted from alumite imported from Rome; the ore is ground into powder and then treated with sulphuric acid which thins down the alum.

The paint is made from an ore imported from Ireland containing 24 per cent. each of tin and lead, this is simply ground into a very fine powder and mixed for paint.

The paraffin works were then visited but there was nothing to complain of there.

There are number of works situated on the other side of the river that were said to be very offensive.

1st. On the east side of Rainham creek there are three manufactories of artificial manures. One where bad fish are treated and fat boiled, reported as being very bad, then comes George Wilson, and Miller and Johnson's Artificial Manure Works.

To the west of Rainham Creek are some Bi-carbon works and others.

Doubtless we are affected at Erith by these works, and it would be well if some steps were taken to enforce them to take every available measure to consume the noxious odours arising from their trades.

Believe me, &c.

F. Parish, Esq. F. B. Jessett, F.R.C.S.E., Medical Officer, Health.

---

To the Erith Local Board,

Pier Road, Erith, Kent,

Gentlemen, 24th November 1879.

The nuisance arising from the Artificial Manure Works since my last report has been, if possible, worse than ever, and I think the time has arrived when you should exert your power to abate this nuisance.

Mr. Collin's works have not been at work lately, as the boiler is out of order, so that the smell must be produced by Messrs. Bevington's on this side of the river.

Clause 114, Public Health Act deals very clearly with the question relating to offensive trades in any urban district, and the preceding clause enables urban sanitary authorities to make byelaws regulating the action of offensive trades.

Clause 91 defines a nuisance in subsection 6 relating to factories, workshops, &c. as being a nuisance or injurious to health, and the following section treats with the method of abating such nuisance.

Clause 115 gives power to urban authorities to deal with any manufactory certified to be a nuisance or injurious to the health of any of the inhabitants of the district of an urban authority when situated without the district.

I trust that the board will take very decided steps to abate this nuisance, as it is undoubtedly a nuisance within the meaning of the Act, and considerably deteriorates from the value of property.

If there is any doubt as to the interpretation of the section above alluded to, would it not be better for the board to instruct your clerk to state the case, and obtain counsel's opinion as to the best course to pursue.

Yours, &c.

F. Parish, Esq. Fredk. B. Jessett, F.R.C.S.E., Medical Officer, Health.

---

To the Urban Sanitary Authority, Erith.

*Annual Report for the year ending December 31st*, 1879.

Pier Road, Erith, Kent,

Gentlemen, 22nd January 1880.

There has been no material change in the general condition of this parish since my last annual report.

The influences threatening to affect the public health injuriously have been in many cases removed, I refer especially to the closing of a number of wells, the water from which has been analysed and found unfit for domestic use. These wells are chiefly situated in the lower part of Erith, and one or two in Northumberland Heath. In every case an order has been issued for the owners to close these wells and supply water from the West Kent Waterworks Company . . . .

I may here mention as threatening to affect injuriously the public health the horrible smells arising from the manufactories on the river. These I shall show later in my report the board are using their best endeavours to put a stop to . . . . .

There have been during the whole year a few cases of scarlet fever throughout the district, but of a very mild character.

There have been 11 deaths, however, caused by it, but in the majority of cases they have been caused by secondary disease brought on from insufficient care during convalescence from the fever.

Five deaths have occurred in Erith, four in Belvedere, and two at Northumberland Heath. It was difficult to ascertain the origin of the fever. In every case, however, strong sanitary measures were taken to prevent the spread of the disease, and this proved very effectual, for at present there is not to my knowledge any fever in the parish . . . . .

I would again draw attention to the fact that undoubtedly a large quantity of sewage sent out from Crossness and Barking is carried by the current on the river on to our shores.

Strenuous efforts should be made to prevent this, but at present the outfalls are protected by the Public Health Act.

*Offensive Trades.*

This is a subject which has occupied the attention of your board for some time, and it is with very great satisfaction that I have found you are determined to use your utmost endeavours to enforce the owners of the different glue manufactories, and other offensive trade's works to abate the nuisance arising from their manufactories.

I have visited, with your inspector, all the works on this side of the river, and sent my report in to you.

I am certain, if the different owners used the very best known measure to abate the nuisance arising from their works, that the smells complained of would be done away with, or at any rate reduced to so small proportion that they would cease to be perceptible at such a distance as Erith and Belvedere.

I would, however, suggest to the board that a petition should be sent to the Home Secretary urging him to introduce his Noxious Vapours Bill Act in Parliament during the coming session, and I think with the coming election in view the members of the county might be written to with a view of their bringing the subject prominently before the Home Secretary.

The mortality of the district, although higher than last year, still keeps very low.

There have been 165 deaths this year as against 142 in 1878, 50 of the 165 deaths were above 60 years of age and 38 under 1 year, being more than half of the whole mortality, of the 50 deaths over 60 no less than 16 occurred at the Royal Alfred Institute, of the 50 deaths above 60 no less than 32 were over 70 years of age, and the total age of the whole 50 amounted to 3,704 years, or an average age of 74 years.

Dividing the deaths among the several districts, viz. (1) Belvedere, including Abbey Wood and the Marshes, (2) Erith, and (3) Northumberland Heath, we shall find the following result, taking the population of each district at the number of population at the last Census, 1871, viz.:

| | Population, 1871. | Deaths. | Death Rate. |
|---|---|---|---|
| Erith - - - - | 4,300 | 73 | 17·6 |
| Belvedere - - - - | 3,320 | 49 | 14·8 |
| Northumberland Heath - - | 675 | 15 | 22·2 |
| Royal Alfred Institute - - | — | 16 | — |
| Cottage Hospital - - - | — | 6 | — |
| Violence - - - - | — | 6 | — |

I have, in the above table, put the whole of the Marshes, Abbey Wood, and the outfall into Belvedere District, and taken out all the deaths occurring at the Royal Alfred Institute which reduces the death rate to a minimum.

The population of that district has not, I think, materially increased since the last Census, whereas Erith population has considerably increased, as also has the Northumberland Heath District.

The death rate for the year, allowing for increase of population, and excluding the deaths occurring at the Royal Alfred Institute is at the rate of 12·5 per 1,000, this is slightly higher than last year, and may be accounted for by the excessively wet cold weather, which has carried off a very large number of old people and children.

Deaths from disease of the respiratory organs, included in Table 29 and 30 of the Tabulated Report, having been unusually high.

Included in this number also are six deaths from accident, four of which were bodies washed up from the river, having been discovered, and, therefore, really not part of the deaths occurring in the district from disease . . . .

In reference to my remarks on the extension of fever, I intended to draw attention to the desirability of the board having a hot room where clothes, bedding, &c. might be brought and thoroughly fumigated and disinfected. By this means, I think, an epidemic, should it arise, might be much more speedily cut short, and the risk of an epidemic occuring, much reduced by early and proper disinfection of the clothes, &c. of those who have fever lightly.

I append the printed forms by which you will see the number of deaths at each age, and the disease of which they died.

I am, &c.

FREDK. B. JESSETT, F.R.C.S.E.,
Medical Officer of Health.

F. Parish, Esq.

*Here follows the tabular statement.*

---

COPY MEMORIAL, signed by 69 RATEPAYERS of BELVEDERE, presented to ERITH LOCAL BOARD on 14th September 1880.

To the Local Board of Health of Erith.

GENTLEMEN,

WE, the undersigned inhabitants and ratepayers of Belvedere, beg to call your attention to the continuous and unabated nuisance arising from the factories on the river banks, the fumes and vapours are having a serious effect upon the health of our families, and we must ask you to put in force any powers you may have to remedy the evil with as little delay as possible.

We are, &c.

---

To the Erith Local Board.

Offices, High Street, Erith,
14th December 1880.

GENTLEMEN,

I HAVE visited the manure and other works on this side of the Thames, according to the instructions I have received.

On Saturday, 4th December, at 8·45 a.m. wind west, Bevington and Co. were boiling, and had been doing so the preceding day, Friday, with the usual smell arising, the concentrator provided to assist in the prevention of smells, had been placed in position and fixed, a concrete foundation for tank for condenser had been put down on cross planks about four inches apart. I found in enlarging foundation side of concentrator the smell from removal of earth was more obnoxious from that of boiling.

Messrs. Callender and Sons had been at work the first five days of the week, and were cleaning and chipping on this day, Saturday, which is their accustomed way of conducting their business.

Monday the 6th instant, at same time, with wind in same direction, I visited Messrs. Bevington & Co.'s works. They were boiling scutch, and intended doing so for the two next consecutive days, which was done, the engineers were still fitting up the concentrator.

At the same date, and near the same time, Messrs. Callender and Sons were at work with the two outside boilers, and shed, where damp coarse sheeting was prepared; the three boilers in shed in centre of premises were having the flues altered, and agitators put into the boilers worked by steam, that they might be covered in, to prevent the escape of gas, to which they were liable when worked by hand, the foreman stated the two outside boilers now at work, would be placed alongside those now being altered, as soon as they were completed, that they might be all under one roof, and worked with same engine.

I have seen an open ditch taking refuse from Messrs. Price and Co.'s works which is offensive, and com-

App. A.J.

plained of by Messrs. Callender and Son's foreman. This I think should be attended to by the Thames Conservancy as it flows into the river.

Friday, December 10th, I found a very bad smell when leaving the office 5.15 p.m., which I should think caused by the boiling of scutch, which must have arisen from works on the Essex side, the wind being about north.

10.30 a.m., December 13th, 1880, Monday, wind west, Messrs. Bevington and Co. boiling, will continue doing so for two more days, and then not again until the alteration of the works are completed; the tank for consider 24′ 0″ × 10′ 0″ × 2′ 6″ is built, and the inner side cemented. The excavation is proceeding for putting down pipes which have not at present arrived.

Messrs. Callender and Sons are continuing their alterations which will take some time before they are completed.

On Friday, December 10th, on passing I found a very obnoxious and offensive smell arising from Messrs. Collins' Work either from the turning of hide chippings or from being placed in solution in vats alongside the river wall.

The drawings left for approval at last board meeting by Mr. Bleeze for house to be built I believe in Brook Street are very vague, and no specification being sent therewith, I would suggest they be amended.

I have also received drawings and specifications for building stables for S. S. Baiss, Esq., Belvedere, which I believe are in accordance with the bye-laws.

The house of Northumberland Heath where typhoid fever occurred has been fumigated with "bi-sulphide of "carbon" in every room.

The dangerous earth on Knee Hill, Abbey Wood, has been removed.

Application has been made and forms filled in for slaughter house licenses for Messrs. C. Weller, J. Hind, W. Smith, G. Alcey, and Mrs. S. Robertson.

Mr. T. C. Hayward, Surveyor of Eltham, would be pleased to know the terms the board would let the steam roller upon and if an arrangement could be made for use of same.

---

*Annual Medical Report for the Year* 1880.

To the Erith Local Board.

Pier Road, Erith, Kent.

GENTLEMEN, January 28th, 1881.

VERY little change has taken place in the general condition of the parish.

Influences threatening to injuriously affect the health of the neighbourhood have been removed as far as possible. A number of wells have been closed especially in the town itself and the company's water laid on.

Other wells are under inspection * * *

There has been very little building in the parish this year. The cottages that have been built are, however, of a very superior character to those built some few years since, especially in a sanitary point of view.

The very elaborate and thoroughly exhaustive plans for draining the whole parish as prepared by Mr. Easton last year are still in your offices but the time has not at present arrived apparently when they are likely to be carried out. In the meantime the whole of the Belvedere, Abbey Wood, and Northumberland Heath District are drained into cesspools.

This is much to be regretted, but doubtless the time is at hand when you will see the necessity of carrying out the very complete system of drainage above referred to.

Your board has during the year taken very active measures to abate the nuisance arising from the different factories along the river. I have inspected and sent in two or three reports upon the condition of those factories situated on this side of the river, and further you have appointed Mr. Ogston (analytical chemist of London) and he has visited not only those factories in your own parish but also those on the other side of the river which threaten to affect injuriously the health of the inhabitants of your district.

The result of your labours has been to enforce Messrs Bevington and Messrs. Callendar to stop their works until such time as they have erected suitable machinery to abate the nuisances complained of. Messrs. Price and Co. are now being attacked and doubtless you will be entitled to enforce them also to erect suitable machinery for the same object.

Having satisfactorily arranged for mitigating the nuisances arising from the factories in this parish you will doubtless during the coming year give your attention to those factories on the other side of the river.

I have visited again the Picardy St. property and find it greatly improved, but the open ditch or, I may say, open cesspool at the end of the street still exists and should be done away with as it must undoubtedly affect the health of the inhabitants in its immediate neighbourhood injuriously.

The privies too are still as bad as ever, and the only means of improving them is to have a thorough system of earth closets superintended by your own Inspector of Nuisances.

There was a very sharp and extensive epidemic of measles at the commencement of the year.

It commenced at Northumberland Heath and here your board ordered the National and Sunday schools to be closed for one month.

The epidemic, however, extended to Lessness Heath and Erith and as the disease was of a very mild type and from experience of closing the schools at Northumberland Heath you found did not stop the tide of the epidemic it was not necessary to close the larger schools at Erith or Belvedere.

Out of the whole number affected only seven died and these mostly from secondary affections such as bronchitis.

There have been a few isolated cases of scarlet fever in the parish. At Northumberland Heath there were a few cases of typhoid fever, one of which terminated fatally. Diarrhœa was prevalent during the summer among infants, but there were only nine deaths.

A few isolated cases of chicken pox have also occurred. The general health of the parish has been very good during the year, the mortality being slightly less than last year, viz. 161 as against 165 in 1879. The death rate of the parish during the year, allowing for increase of population, is 1,464 per 1,000.

Thirty-nine of these deaths were over 60 years of age and 44 under one year.

Twelve deaths occurred at the Royal Alfred Institute and four in the Cottage Hospital.

Dividing the deaths between the several districts, viz. (1) Belvedere including Abbey Wood and the other marshes; (2) Erith; and (3) Northumberland Heath, you will notice the following death rate taking the population of each district at the number of population of each district at the number of population returned at the last census.

| — | Population, 1871. | Deaths. | Death-rate. | Measles. |
|---|---|---|---|---|
| Belvedere - - - | 3,320 | 61 | 18·4 | 2 |
| Erith - - - - | 4,300 | 60 | 13·95 | 5 |
| Northumberland Heath - | 675 | 12 | 17·6 | 2 |
| Royal Alfred Institute - | 675 | 12 | — | — |
| Cottage Hospital - - | 675 | 4 | — | — |
| Violence - - - - | 675 | 12 | — | — |

Comparing this table with last year you will notice that Belvedere heads the poll considerably, having jumped from 14·8 per thousand in 1879 to 18·4 in 1880, both undoubtedly very low death rates. Erith, on the contrary has dropped from 17·6 per thousand in 1879 to 13·95 in 1880 while Northumberland Heath remains about the same.

The number of deaths in Erith for were 1879 76, as against 60 for 1880, while Belvedere showed 49 in 1879 and 61 in 1880.

The number of births in the whole district was 336 or rather more than two to every death registered. I append hereto the usual tabulated forms as furnished by the Local Government Board, which will show you at a glance the ages and diseases from which the majority of the deaths occurred. A table of new cases of sickness has been added, and through the dispensary books I have been enabled to tabulate a large number of diseases that otherwise it would be impossible to collect particulars of.

Believe me, &c.

F. Parish, Esq. FREDK. B. JESSETT.
Clerk to the Board.

---

To the Erith Local Board,

Pier Road, Erith, Kent,

GENTLEMEN, February 27th, 1882.

I HAVE to report a death from typhoid fever occurring in Queen's Road, Erith.

The sinks in the cottages in this street run direct into the drainage and the small bell trap, which affords the

only protection to sewer gas coming into the houses, are in many cases out of repair. This should be altered and the pipe from the sink be disconnected from the drain leading into the sewer.

The Company's water is laid on here, stand pipes being provided to each cottage over the sinks, the occupiers catching what water they require during the short time the water is turned on. I think it would be better if proper cisterns were provided for these cottages. * * * * * *

*Noxious Vapours.*

The smells from Messrs. Proctor and Bevington on Tuesday, February 21st and Thursday 23rd, were worse than I ever smelt them. On Tuesday the wind was N,N.E., and on Bostol Hill the smell was such as to cause patients of mine to close their windows although it was highly essential for them to be open.

On Wednesday a most sickening smell pervaded the neighbourhood. I believe from the state of the tide it must have been sewage. The wind was N. and the smell worst at Beadle's Wharf.

I have to draw your attention to a low wall which exists behind Mr. Stone's yacht building yard. Here a man fell over and was killed.

In this same yard the privy accommodation is very bad.

Yours, &c.
(Signed) Fredk. B. Jessett,
F. Parish, Esq. Medical Officer of Health.

---

Pier Road, Erith, Kent,
February 28th, 1881.

To the Erith Local Board.

*Noxious Vapours.*

Gentlemen,

The effluvia from the glueworks was very bad indeed on Wednesday, February 16th.

I don't know whether it came from Messrs. Bevington or Collins, but it was reported to me by many inhabitants as being as bad if not worse than ever. It would be as well, I think, if your inspector made inquiries as to who was working on the day mentioned.

*Small-pox.*

A case of small-pox has been reported to me at Mr. Barnes, grocers, North End. I have given instructions to have the shop closed, and have written to the inspector of Crayford parish, to issue notices to the owner of the shop; also to supply the necessary disinfectants.

Believe me,
Yours, &c.
Fredk. B. Jessett, F.R.C.S.,
F. Parish, Esq., Clerk. Med. Off. Health.

---

22, Mincing Lane, E.C.,
15th March 1881.

To the Erith Local Board,

Gentlemen,

In accordance with your wishes conveyed to me in a letter from Mr. Parish on the 4th instant, I have made another visit to the factories on the south side of the river, and have to report to you the condition in which I found them.

Messrs. Callendars were not at work on the day of my inspection, but I find they have attached to one of their boiling pans an apparatus which they believe will prevent the escape of oily vapours into the air. This consists of a corrugated iron fitting fairly closely over the pan or boiler from which, at one end a pipe enters, connected with the furnace above the fire bars. The anticipation is that the vapours which have been proved to be so offensive, will in passing over the fuel, in contact with the hot flue, be burnt up to become innocuous. My impression is that this plan will not be effective because the considerable amount of watery vapours which as well as the oil is discharged during the boiling will keep down the temperature of the whole, below the point at which combustion would take place. There would have been a better chance of success in my opinion if the pipe leading from the pan had been taken below the furnace instead of above it. Mr. Callendar told me they were to commence working on the 14th March (yesterday) so that with a favouring wind the result will soon be known in the neighbourhood. It will be remembered that in one of my reports to you, I expressed the opinion that some arrangement by which the shale oil vapours should be condensed would give the greatest security against annoyance, and I fear that with a varying intensity of fire under the boilers the plan now being tried can scarcely be expected to give uniform results, if indeed it provides any serious remedy.

Messrs. Price's works were visited, but I was not fortunate enough this time to meet Mr. Harvey. With regard to the particular process of which I have more than once spoken, viz., the refining of oil by means of sulphuric acid, and about which complaints were more than justified, Mr. Harvey told me that an alteration was to be made in the situation of the building in which the process was carried on, and that some alterations in the process itself was to be made, but Mr. Harvey did not say that the steam conveying acid vapours from the refining cisterns into the air was to be condensed and so got rid of, so far as Erith is concerned. This, as I have more than once explained, will be found to be necessary, and as it can be done with very little cost without interfering with the course of the business, I think it ought to be provided for at once. The treatment of the oil occupies, I believe, two hours every day, but it was not going on whilst I was present. One other disagreeable vapour, which has up to quite lately been allowed to escape into the air, is now conducted by a pipe into the furnace below the boiler in which it is produced, here it is said to be destroyed; the resulting gases passing into the chimney, and so, of course, out of the range of observation whilst I was on the premises. It was smelling very much whilst I was there, but the manager explained that this was due to a defective pipe through which the vapours were leaking, and that this fault was to be immediately remedied. Many of Messrs. Price's processes are evidently intermittent; it is impossible, therefore, for me to say if there are more than those I have mentioned to which their attention should be drawn, and it can only be after putting an end to the offensiveness of those that are known to be objectionable, one by one, that certainly on this point can be arrived at.

Mr. Collins' factory was not open to me, and I am, therefore, unable to inform you of its internal condition. There is great prepartion for work on a considerable scale, both for glue making and scutch boiling, as evidenced by the collection of large quantities of material on the wharf, and it is certain that unless great improvement in the boilers and machinery, I saw at my last visit is made, before they commence to work very great annoyance will be created in the neighbourhood.

Messrs. Proctor and Bevington. This firm have put up some extensive machinery with the view of condensing their acid vapours and dying their manure completely in mixers before it is exposed to the air. If the apparatus is as successful with their compound as it has shown itself to be in other cases, the result should be satisfactory since nothing is allowed to escape. On the occasion of my visit on the 8th, however, some difficulty was experienced in the working of the machine almost for the first time, and a good deal of vapour was escaping from the boiling pans, Mr. Bevington told me they had spent 700*l.* upon the machine, and some faults having shown themselves in it they were about to make alterations and hoped to get good results.

Messrs. Bevington have always seemed to me to be seriously endeavouring to do the best they can, but I must say there was a good deal of smell on Tuesday last, owing I could see, in a great measure to the want of experience of the new machines on the part of those in charge.

Inasmuch as in only one instance is there any admission on the part of owners of factories that the slightest annoyance is occasioned to the neighbourhood by anything proceeding from their respective works, opinion on this point can only be formed from the outside, and as I have no doubt they honestly believe what they say, it will still be necessary to draw their attention after careful observations to the odours which can be distinctly traced to them individually.

It is scarely necessary to draw your attention again to the works upon the north side of the river. Messrs. Crossfield, Messrs. Miller and Johnson, and Messrs. Wilson, the former more especially are with fair winds sending "noxious vapours" to Erith and Belvedere,

App. A.J.

and undoubtedly they ought if possible to be prevented from doing so.

I am, &c.
(Signed) G. H. Ogston.

---

Mincing Lane, London, E.C.,
30th August 1881.

To the Chairman of the Erith Local Board,

Dear Sir,

In consequence of a letter from Mr. Parish, intimating your wish that I should again visit the factories on the south bank of your river on the 16th of this month, accompanied by your surveyor, I inspected all those that are mentioned in my former reports ascertaining what changes had been made in them, and what was proposed to be done.

Proctor and Bevington have completed the erection, and have worked the apparatus to dry their manure, and at the same time to condense the vapours arising from it. A considerable sum of money, 700*l.*, I believe, has been spent upon it, but I understand the machine is not yet a complete success. How far it falls short of this I cannot say, as on the 16th it was not at work, and additions are still being made to the apparatus. The character of the material with which Messrs. Proctor and Bevington have to deal differs considerably from the simple refuse fish that those gentlemen saw so completely dried when they made the purchase of the machine, and I regret they did not adopt my advice to experiment with their own stuff before adopting the plan. I did not see either of the partners, but pointed out to their manager a mode of working by allowing the mixture to cool to a certain point in the cylinder before discharging into the pits, which will mitigate the nuisance, until the additions are completed, and which it was promised should be adopted.

Messrs. Collins have not been boiling "shutch" since my last visit, and have made no alterations whatever in plant provided for the purpose. They are intermittently engaged in making glue, and have a large quantity of the material from which it is produced on the premises. There was, however, nothing to complain of, and, indeed, glue making if properly carried on need create no nuisance.

A fish-drying work, immediately adjoining Messrs. Proctors' on the upper side which have been working for some time past, are being put into repair, but I could not learn from the men engaged on the engines who were the proprietors, or what class of business it was proposed to carry on there. If fish-drying is to be re-established, attention should be directed to the place.

Sir Chas. Price and Co. have made some alterations in their works that will diminish the quantity of noxious vapours and some smells that were noticeable at my last visit to their works. Notably they have fixed a powerful, and I should think an effective condenser, to intercept the volatile acrolive resulting from the distillation of glycerine. Some months ago much of this escaped into the air, partly from a pipe which was leaking, but care seems to have been taken to put an end to this source of complaint. They have also erected air-tight cyclinders for the reception of offensive "cotton "oil foots" which comes alongside their wharf in "barges, and is drawn directly into these receptacles by exhausting them of air so that no exposure of the foots is allowed. This, no doubt, will be a great improvement.

With regard to a complaint I made to Mr. Harvey, that in refining some of their oil by steam and sulphuric acid and all the sulphurous vapours were allowed to pass into the air and suggesting that means ought to be taken to prevent their escape. I enquired of the manager if any change had been made in this direction, and he referred me to Mr. Harvey for information on this point. As on every other subject he gave me every possible assistance. I suppose that condensation of the vapour of which I complained has not been arranged for. This, in my opinion, ought to be done, as the escape is, I am told, of daily occurrence, and could be accomplished with little expense and without interference with the process.

Messrs. Callender have adapted to all their existing boiling pans a cover so arranged as by means of a large outlet pipe to conduct the vapours immediately into the furnaces below the pans. The arrangement in the first pans they altered appeared to me to be imperfect, inasmuch as the volatile matters were led above the fire bars instead of below them, the effect being to allow them to pass practically unchanged into the chimney in place of being destroyed by passing through the heated fuel. I pointed out this defect at my last visit, and the two other pans have been fitted as suggested. The works were not in operation, and I am therefore unable to say if the destruction of the noxious vapours is absolutely effected. The report of your surveyor after having seen the boiling going on, is however satisfactory, both as regards boiler house and a new process for impregnating cloth with their bitumen, which, when I saw the means provided for the purpose, seemed likely to produce a good deal of vapour and to cause annoyance.

The passage of the cloth into water directly it issues from the hot bitumen as described, will certainly, to a great measure, prevent the escape of this vapour.

The condition of the district is certainly greatly improved, and when Messrs. Proctor and Bevington's machinery is complete, and alterations are made in the retiring process at Sir Charles Price and Co.'s works, it is to be hoped the factories on the south side of the river may be worked without annoyance to the neighbourhood.

I am, &c.
(Signed) G. H. Ogston.

---

*Sanitary.*

To the Erith Local Board.

High Street, Erith,
November 1881.

Gentlemen,

From instructions received at the last Board meeting I have inspected the factories on this side of the Thames five different days, at different times each day. Messrs. Callendar and Sons commenced boiling on Monday, October 31st with the boilers that had been altered after discontinuing more than two months, and have done so since up to date, except on Saturday, on which day they do not boil, a great improvement is visible since notice was first given them, but the smell is not quite disposed of. Messrs. Price and Co.'s works I have not examined internally, only going round to ascertain the smells that arise therefrom; they are less than they were; the smell from ditch is also better, but not what it should be. Messrs. Berger, Spence, and Co. are doing but little, that is, grinding metallic ore for paint and melting small quantities of their metal for statuettes, busts, &c. for experiments. No disagreeable smell arises from these works. Messrs. Collins and Co. have received a large quantity of lime foots from tan yards for making into manure, this is mixed with lime and sulphuric acid, which evolves a non-pleasant smell, there is also drainage from these and the adjoining works; a quantity of stagnant water when stirred is very offensive. Messrs. Proctor and Bevingtons did not boil from October 20th until November 1st, and continued on November 1st, 3rd, and 4th, the refuse from concentrator is passed out in a semi-liquid state, and cannot be wheeled away until the next day; this, and having to dry it on kilns, allows a bad smell to escape, the alterations that have been made in the process of boiling have very much decreased the smell in that part of the work. Messrs. Johnstone's are at present using the old machinery that was fixed in their factory for drying and grinding the refuse from some of the London warehouses, the smell of which at present is not offensive and does not travel.

I observed a very offensive smell in my house on Sunday last about 5.30 p.m., which must have arisen from Messrs. Price's works or from works on the Essex side, as no other works in this district were at work; I also think from the opportunities I have of watching the manufactories on the Essex side of the river the most offensive smell arises therefrom, the smell from the river itself when the wind is favourable can scarcely be observed, which is very different to what it was some six weeks since.

---

Local Government Board,
Whitehall, S.W.,
Sir, 26th October 1881.

I am directed by the Local Government Board to transmit you herewith, for the consideration of the Erith Local Board, a copy of a letter which Mr. J. D. Lee has addressed to the Board renewing his complaint as to

the nuisances caused by noxious vapours emanating from manufactories in the neighbourhood of Erith, and adverting to your letter of the 25th April last I am to request that the Board may be furnished with the observations of the local board upon this subject.

I am, &c.
(Signed) Walter J. Sendall,
Assistant Secretary.

To F. Parish, Esq.,
Clerk to the Erith Local Board,
Erith, Kent.

To the Secretary of the Local Government Board,
Whitehall, London.

The Oaks, Belvedere Park,
Sir, October 17th 1881.

Referring to your letter of 5th May 1881, enclosing a reply received from the local board, bearing date of the 29th of April, I now regret to say that although the manufacturers have had a reasonable time for improving their machinery, that on my return to the Oaks after six months absence, the offensive vapours are as bad as when I left, and I can see no remedy but having at the age of 70, with my wife, to sacrifice my property and leave the neighbourhood. My neighbour who is on the Board is of the same mind, for he is powerless at that Board, the manufacturing element being too strong to carry out any suggestion of his.

During my absence a dear friend in the line of stench had occasion to call in Sir William Jenner on a case of gastric fever. On Sir William's arrival he enquired what the horrid smell was, and on being informed it was from the factories, his remark was "Death, death; get out of it as soon as possible." The poor fellow is out of it now—passed away—and his sister down with a similar attack.

I am aware that Mr. Ogston is claiming credit for having in a degree stopped the stench. I have to say that all day Sunday and again this morning it is dreadful, and I now learn that the Board have granted a license to a man to make manure from the condemned fish from Billingsgate, within half a mile of Erith, although at the same time it is proposed to put up a fever hospital on a piece of ground belonging to a member of the local board. Under these circumstances I must again throw myself upon the protection of the Local Government Board.

I have, &c.
(Signed) J. D. Lee.

Walter Sendall, Esq.

*Sanitary.*

To the Erith Local Board.

Offices, High Street, Erith,
Gentlemen, 13th September 1881.

Eight open privies in Claremont cottages have been panned and trapped, six other privies nearly adjoining are in a similar state as when last reported.

The manufactories on this side of the Thames are working in a satisfactory manner. Messrs. Proctor and Bevington have had the connection of pipes to the condenser made good, which has caused a beneficial effect, the others are in a similar manner as when last reported.

On Thursday September 8th a very offensive smell arose from the river, worse than I ever noticed.

To the Erith Local Board.

Pier Road, Erith,
Gentlemen, 20th December 1881.

I have to report that there are several slight cases of whooping cough in the parish among children.

I have cautioned those that have come under my notice to keep away from school for a time.

The parish is, I believe, perfectly free from every other infectious disease.

The smell from Price and Co.'s factory was very bad indeed on Tuesday, December 13. The wind being N.W., blew the effluvia straight across the town of Erith, and I smelt it even at the Saw Mills, Crayford.

I drew the attention of some people to it, who all condemned it as being most offensive and sickly.

Yours, &c.
F. Parish, Esq. (Signed) Fredk. B. Jessett.

To the Erith Local Board.

Pier Road, Erith, Kent,
Gentlemen, January 25th, 1882.

There have been 114 deaths during the year 1881. This is an extraordinary diminution in number as compared with any previous year. Thus in the year 1878 there were 147 deaths: 1879, 165, and 1880, 161, or taking the three districts of Erith, Belvedere, and Northumberland Heath and the public institutions, the number of deaths are as shown in the following table:—

| District. | 1878. | 1879. | 1880. | 1881. |
|---|---|---|---|---|
| Erith | 68 | 73 | 60 | 54 |
| Belvedere | 55 | 49 | 61 | 38 |
| Northumberland Heath | 12 | 15 | 12 | 14 |
| Cottage Hospital | — | 6 | 4 | 9 |
| Royal Alfred Institution | — | 16 | 12 | 4 |
| Violence | 7 | 6 | 12 | 6 |

The above table shows a universal improvement in the health of the parish; no one district fares better than its neighbour, and although Northumberland Heath maintains about the same number of deaths, yet it must be remembered that this district has been built upon more in proportion than any other.

There has been a total absence of any epidemic. There has not been a single death registered from either scarlet fever, measles, whooping cough, or any of the continued fevers, while there has been only one death from smallpox.

It will be observed that the death-rate is very much less than in any previous year, the rate being this year only 11·1 in 1,000, whereas in the year 1879 it was 13·7 in the 1,000; 1880, 14·63; these figures however were fallacious, as I allowed for a larger population than there really was.

The cases of typhoid fever which occurred at the Northumberland Heath district were confined to one family, and with the exception of the young man who died in the latter part of the year 1880, they all made a good recovery.

Of the few cases of scarlet fever that occurred in the Belvedere district, all did well; the disease was of a very mild type and limited to one or two families, thanks to the great precaution taken, no spread of this disease occurred. There has been one death during the year from diphtheria in some cottages situated behind West Street. These cottages are supplied by a well for drinking water, which well is in dangerous proximity to the closets and cesspool. The water was however twice analysed by the public analyst and reported fit for drinking purposes. The well therefore, much against my will, still exists. A few wells have however been closed during the year, and water laid on from the company's main. I find in Erith wells have been closed in Pier Road, Crayford Road, behind the King's Head, Bexley Road, West Street, Queen's Road, and Lesney Farm; to all of these water has been laid on from the West Kent Waterworks Company's main. In Belvedere wells have been closed in Cheshunt Road, Standard Road, Picardy Road, and the Royal Alfred Institution, the company's water being substituted.

A number of new cottages have been built during the year, viz., in Erith 16, Belvedere 18, and the new police station, Northumberland Heath, 19 new cottages have been added making 53 in all. Many of these have been drained into the Erith drainage, while the others have good cesspools formed according to the bye-laws. The scheme for draining the whole parish is still in embryo, and there is a possibility of the Metropolitan outfalls being carried further down the river, and as the present system appears under your supervision to answer fairly well, I cannot urge upon you to take any very active steps in the matter. While upon this topic I was most pleased to see that your Board fully entered into the vital importance of endeavouring to enforce the Metropolitan Board to do something to abate the

App. A.J.

abominable nuisance they are causing by pumping the enormous amount of sewage into the river at Crossness and Barking, the greater part of which must of necessity be deposited upon the banks of the river, as it has proved beyond dispute that the sewage that is pumped out of the river at the commencement of the ebb tide can never get lower down the river than Gravesend, while that which is pumped out later on the ebb can get no further than your parish before it is met by the flood tide to be carried up the river to Woolwich, Blackwall, and even London Bridge, the sewage that had been pumped out earlier on the ebb being returned to our shore from Gravesend, Greenhithe, and Northfleet.

Much no doubt will be made by the advocates of the present system of disposing of the sewage of London at the two outfalls of the excessively low death-rate of this district and also of the nearly total absence of all fevers; but, gentlemen, there are few among you who do not remember the vile stench emitted from the mud on our shores at low tide during the excessive heat of last summer. Without exception, I will venture to assert all the yachtmen who lay off our town will agree as to the filthy masses of black sewage washed backwards and forwards by their yachts during that excessive heat and of the stench emitted from the river generally. It was a source of some surprise to me that fever of the most virulent type was not manifest among the crews of these yachts, but thankful must we be to think we passed through this summer without any such outbreak; but we cannot but look with a wholesome dread at the summer to come, and I should not be doing my duty if I let this subject pass without urging upon you the great importance of your taking active steps to help and co-operate with those gentlemen who are moving in the matter in the hopes that some effectual means will be adopted to abate this gigantic and ever-increasing nuisance. I would even go further and say that the Local Government Board will be failing most egregiously in their duty to all the inhabitants of the different districts on either side of the Thames below London Bridge if they do not institute a most searching inquiry into the whole matter. It is not at this time of the year, gentlemen, that we are likely to suffer, as now, on account of the large proportion of storm water mixed with the sewage, it is so diluted that possibly little harm is likely to accrue; moreover, the temperature is such as not to encourage fermentation or chemical decomposition, but it is in the summer when the concentrated essence is thrown out of these two outfalls. We are told the Metropolitan Board intend enlarging the tanks at the outfalls; is this likely to improve matters? I say, emphatically, No. The only possible use of these large tanks will be to prevent the bursting of their sewers and the flooding of the property around Lee and other localities that have of late years been deluged with sewage during heavy rains and storms. But we do not want to go further when we read that the report of the London Sanitary Committee on Thames outfalls contains, besides statements such as I have mentioned above, a description of sample extracted from the river at various places and chemically tested. Without going into much detail, it may be mentioned that samples taken off Barking contained one fifth of their bulk of sewage.

The total solid residue was in this case 831 grains per gallon from one sample and 570 from another, the loss on ignition being set down at 375 in the first case, and the total of chlorine per gallon amounting to 260 and 280 grains respectively.

Another very interesting and highly instructive fact is that which shows the increase in 10 years on the gross amount of liquid discharged into the river from the two outfalls. The increase goes on year by year at a pretty steady rate; and the total rises from 17½ million gallons in 1863 to over 27 million in 1878 from Crossness outfall, while at Barking the increase is still more remarkable, the advance being from considerably under 13 millions in 1868, and more than 30 millions in 1878. That this state of things is a disgrace to the nation every one will, I think, agree, and if allowed to continue this huge cesspool between Blackwall and Gravesend will be worse than that which existed at Westminster years ago, and will undoubtedly, if not done away, bring among all our shipping an epidemic which will not be surpassed by the great cholera epidemic which existed in London before the drainage was carried to its present outlets.

*Noxious Vapours*

Much has been done during the year to abate the nuisances arising from the escape of noxious vapours from the factories along the river. Messrs. Callander, I think, have succeeded tolerably well in doing away with any nuisance arising from their works. Messrs. Price & Co. have introduced some improvements, but they still, during one process of the manufacture, emit a most offensive effluvia; this will, I hope, before long be overcome and the nuisance therefrom abated. Messrs. Collins and Bevington have not yet succeeded in stopping the nauseating smells being emitted from their works, but they have made many improvements, and doubtless they will succeed in effectually stopping any vapours escaping which will be a nuisance to the neighbourhood. A new manufactory has been started by Messrs. Johnston, just above Messrs. Bevington's; this factory threatened to be a great nuisance, but, thanks to the precautions taken by your Board, I do not think any great inconvenience is likely to arise from this firm. The gasworks often emit very disagreeable fumes from the lime which is thrown out of these works after it has been used to purify the gas. I think more care should be taken by the company to avoid this nuisance. During the coming year the new Alkali Act comes into force, and doubtless an inspector will be appointed for this district to watch the different factories, and stop any manufacture which may be a nuisance to the neighbourhood.

Believe me, &c.
(Signed) F. B. Jessett, F.R.C.S.

---

To the Secretary, The Local Board.

February 22nd, 1882,
Bastal Hill School,
Abbey Wood, Kent.

Sir,

Yesterday afternoon the smell from the marshes was intolerable.

This evening we were visited by a worse stench than I can remember. Directly I discovered it I had to rush and close every aperture looking north.

When it began I cannot say. It had made its way into my study at 7.15 a.m., and when I went out to investigate, I found the passages full of it, and it was almost impossible to stand at my front door.

By 7.25 it had sensibly diminished.

Will you kindly call the attention of the Board to this statement?

I am, &c.
(Signed) Frederic Wood.

P.S.—I have just seen the postman, and he tells me this stench had lasted quite an hour.

---

Belvedere, February 23, 1882.

Inspector of Factories on the Riverside, Belvedere Marshes.

In consequence of a very disagreeable stench at Belvedere Mr. Strickland requested me to find out what factory it came from. In tracing it I found it came from Messrs. Proctor and Bevington. I walked round the whole of the factories on the marshes, and the wind was bringing the smoke from the factories on the other side of the river, but I found no bad stench from any but Proctor and Bevington's.

4 o'clock p.m.
Wind N.E.

James Blake.

---

The Tower, Belvedere Park,
February 28, 1882.

My dear Sir,

I regret the state of my health has and will prevent my attending the meetings of the Erith Local Board for some time to come.

On the 23rd inst., and some days previous, the stench from the factories was at times awful; on the latter it was so bad that I asked Mr. Strickland to send the person who had previously been employed to watch the factories; he states that the stench came from Messrs Proctor and Bevington's. I thought the Government Surveyor would have been at Erith last month. If I do not hear from you that he is coming very shortly I must write to the Government Local Board, and remain

Yours truly,
Robt. V. Asser.

Wm. Anderson, Esq.,
Chairman,
Erith Local Board.

Utrecht House, Abbey Wood,
March 17th, 1882, 6.45 p.m.

Dear Sir,

I think it right to draw your attention to the fact that there is now a most noxious smell overhanging this district. I have just been on Bostal Common, where the stink was so bad that it was impossible for me to continue my walk. I think that what I now complain of is about as bad a smell as anything we have ever had. There is but very little wind, and what there is, is coming from the north-west.

Kindly bring this communication to the attention of the Local Board.

I am, &c.
Geo. A. Cape.

F. Parish, Esq.

---

Annual Report for the year 1882.

To the Erith Local Board.

Erith House, Erith, Kent,
January 1st, 1883.

Gentlemen,

At the early part of the year there were several cases of small-pox in the parish, all of which had been imported, the sufferers having contracted the disease either in London or Woolwich. Strict precautions, however, were taken, and the disease was in each case confined to the family in which it had occurred; one death, however, occurred in a child, the others all made a good recovery.

Scarlet fever was also prevalent in the early part of the year, and two deaths were registered. Strict antiseptic precautions were taken and the disease did not spread to any appreciable extent.

Whooping-cough was very prevalent throughout the whole parish in the spring, and caused a rather large number of deaths among infants; as the summer advanced, however, the disease gradually subsided.

During the latter part of the year there has been a very universal epidemic of measles, which, however, was of a mild type, and although several infants succumbed to the disease, yet it never assumed such proportions as to cause me to advise the school board to adopt any very stringent measures.

During the year there have only been a very few isolated cases of typhoid fever; one case, however, died from relaxation of the bowels following the fever.

A few more wells have been closed during the year, and there now remain only a very few in the parish, and for the health of the district the sooner they are closed he better.

There has been a good deal of building in the district during the year; new shops have been erected round the public hall, and some good cottages have been built in West Street; at Northumberland Heath a large number of very superior cottages have been erected, while at Belvedere some very excellent villa residences have been built, as well as many good cottages in Leather Bottle Road and Harrow Road. As these have been built according to the Board's byelaws, and under tke supervision of your inspector, it is fair to presume that the sanitary arrangements of all these houses have been attended to in first-rate manner.

The action your Board with other influential company and individuals have taken respecting the metropolitan outfalls has borne good fruit, a Royal Commission having been granted this body of gentlemen; have sat now several times, and most voluminous evidence has been given, all pointing to the terrible nuisance the pumping of the sewage into the river at Crossness and Barking causes; and I have very little doubt that evidence of such weight and importance will be the means of causing, at no very distant date, the Metropolitan Board to do something to abate this ever-increasing nuisance.

I wish I could congratulate you upon the results of your action in endeavouring to do away with the vile and nauseating stenches emitted from the factories on the river sides, both on this side of the river and on the Essex shore. The stenches emitted from these factories on many occasions during the year have exceeded, if it were possible, those of previous years, yet, as far as I can discover nothing has been done for a length of time to strive and abate the nuisance. I would urge upon you, however, in the coming year to direct your attention in this direction, as these smells are the means of detracting from the value of property in this parish, and apart from that I believe it to be indirectly injurious to health. It is true Mr. Ogston has been instructed to visit these factories; but without it is with a view of his collecting evidence to prosecute the delinquents, I contend you are doing the very thing by his visits which would strengthen the hands of the manufacturers, as if he passes their machinery as being the best, in his opinion, to abate the nuisance, I fear, if it came to active measures being taken, you would find, he acting as your representative having passed the machinery, would tell very much against you. Doubtless, however, during the coming year you will direct your attention to this matter.

App. A.J.

The disinfecting shed has been fitted and erected during the year. This is a subject on which you are to be congratulated, as if any epidemic should arise now you have a place in which all the bedding, clothing, &c. can be most thoroughly and efficiently disinfected, and I trust you will in years to come insist in all cases of fever, small-pox, and other infectious diseases that all the clothing, bedding, &c. shall be taken to this disinfecting shed and thoroughly fumigated and baked.

No doubt the Board that has seen its way to erecting this most essential building will ere long see the desirability of following up their efforts by advising the erection of a small infectious diseases hospital.

I would also direct your attention to the state of the public mortuary. I some time ago suggested that a proper table with a slate slab should be placed there, but up to the present time the old table still remains there, which is a disgrace.

I would also suggest that your inspector be instructed to visit this place from time to time and see that it is kept clean and in proper order; also a supply of towels, soap, pails, basins, should be kept there, as well as some weights and scales. I mention this last, as the coroner often in the course of his inquiries requires to have the weight of the different organs of the body when it might be of the greatest importance in enabling the jury to arrive at a true verdict.

I was sorry to find the annexation of the Arthur Street district to this urban district had been abandoned, as I look upon this part of Crayford parish as a most fruitful source of fevers to Erith that can be. It is badly drained; there are still wells open which are in dangerous proximity to cesspools. The new cottages erected there are, many of them, disgracefully built; in fact I know of few places that require more looking after than this district, and I am quite sure, if you could see your way to annexing it under your government, that much may done not only for the poor people living there, but also in all probability in preventing disease being imported into your own district.

The health of the parish generally has not been so good as last year, but better than in the two preceding years. The total number of deaths has been 158 as against 114 in 1881, and 165 in 1880, or taking the different districts, as I have done in former years, it is as follows:—

| District. | 1879. | 1880. | 1881. | 1882. |
|---|---|---|---|---|
| Erith - - - | 73 | 60 | 48 | 59 |
| Belvedere - - - | 49 | 61 | 33 | 52 |
| Northumberland Heath - | 15 | 12 | 14 | 20 |
| Cottage Hospital - - - | 6 | 4 | 9 | 5 |
| Royal Alfred Institution - | 16 | 12 | 4 | 5 |
| Violence and Inquests - | 6 | 12 | 6 | 17 |

The death-rate for the year is 15·8 per thousand; this is in excess of the previous year. I have always allowed for an increase in the population rather in excess of what the last census proved to be correct. This year, however, I have I believe allowed scarcely a sufficient increase, as on account of the number of men employed at Messrs. Shuttleworth and Chapman's, and the excess of births over deaths, I think the population now must be more than 10,000. The number of births this year has been 348 as against 321 in 1881.

As this is the last report I shall have the honour of making to you in my capacity as medical officer of health to your district, allow me to thank you for the courtesy you have always shewn, and for the kind manner in which you have listened to and endeavoured as far as possible to carry out any suggestions I might have thought right to place before you. If at any time feeling strongly upon any subject I may have expressed myself too freely I am sure you will understand my reason for doing so was that I always have had and always shall have the welfare of Erith at heart.

Believe me, &c.
Fredk. B. Jessett, F.R.C.S.E.,
Med. Off. Health.

Mean flow, 833,115,000 gallons per diem, or 92,568 cubic feet per minute, from 1853 to 1880.

## APPENDIX B.S.

*Put in by Dr. Collingridge.* *See QQ. 6764 and* 16,799.

Port of London Sanitary Offices,
King William Street, Greenwich, S.E.,
22nd July 1880.

Extracts from Monthly Report of the Medical Officer of Health, Port of London, affecting West Ham Pumping Station in Bow Creek.

Perhaps the most important event in connexion with the river, so far as the health of our great city is concerned, has been the publication of the report and determination of Captain Douglas Galton and Mr. Frederick J. Bramwell, the arbitrators appointed by the Metropolitan Board of Works and Conservators of the Thames to settle the question of obstruction to navigation by the deposit of mud banks caused by the outfalls at Barking and Crossness.

After a lengthy and exhaustive inquiry they determined—

1. That the navigation in the Barking and Halfway Reaches far from being injured by the sewage outfalls is actually in a better condition now than it was before those outfalls were opened;
2. That each of the three banks, viz., Barking, Margaretness, and Crossness, has arisen from the dredging operations of the Thames Conservators themselves in obedience to well-known laws;
3. That the river always contains a large quantity of suspended matter, of which the major amount is mineral, and to which the metropolitan sewers contribute but a very small proportion;
4. That the three banks have been formed from the suspended solid matter;
5. And, therefore, that the three banks cannot be said, in the sense of the Act of 1870, to have arisen from the flow of the sewage at the outfalls, and that consequently the Metropolitan Board of Works should not be called upon to remove them.

Thus this determination has very decidedly settled for many years to come the question of position of these outfalls, at any rate so far as an interference with the navigation is concerned.

The question, however, of other outfalls above these is still a serious one, and likely to give trouble to the river authorities in the future. One which has come more particularly under our notice recently is the West Ham Pumping Station, situated about a mile up Bow Creek.

The attention of this authority was called to the outfall by a letter from a barge owner living a short distance below the station, in which he stated that for some time there had been a very great nuisance in consequence of the sewage finding its way down the creek and being deposited on the banks, whence it gave rise to an extremely offensive smell, and that on account of the foul odour and its effects he was unable to men in his employ for any length of time.

Under these circumstances, I felt it my duty to make a careful inspection of the creek. This was done on the 4th June at high tide, at which time the water appeared fairly good, though somewhat turbid. There was no perceptible odour of sewage, and obviously nothing could be seen of the alleged deposits.

I visited the pumping station, and was informed by the manager that the sewage was treated by precipitation with lime; that after settlement the supernatant fluid was allowed to run into the river.

The sludge thrown down is allowed to dry, and is then compressed by powerful machinery into flat discs.

The rate of flow into the creek is about 4,000 gallons per minute, and as this continues for 16 or 18 hours a day, it must necessarily be continued at all states of the tide.

On the 17th, a second visit was made at low water. It was then found that a large deposit of undoubted sewage, mixed with the ordinary river mud, was thrown upon the banks in certain parts. When this is removed by barge builders from their hards it is returned at the next tide. At the time of inspection there was a full stream issuing from the pumping station sluice, which smelt very strong, was of a dark colour, and in which were floating masses of fæcal matter.

On the banks surrounding the outfall were large masses of rags, paper, and other materials usually found in sewage. Samples both of mud and water were taken, and have been examined.

In the two or three cases of illness which have occurred recently, said to be due to the noxious odour, the symptoms were similar, viz., vomiting and diarrhœa. The offensive character of the mud is said to be on the increase, and must of necessity prove more injurious during hot weather.

It should also be mentioned that there are a number of privies and other small outfalls emptying into the creek. Of these a complete list has been made, and your medical officer will call upon the proper authorities to remove them.

App. C.C.

# APPENDIX C.C.

List of Witnesses who have not yet been called.

*See conclusion of Forty-sixth Day's Proceedings.*

(A.) By the General Committee.

| Name. | Address. | Occupation. | Nature of Evidence. |
|---|---|---|---|
| Charles Stirt Milnes | Coal Exchange | Coal merchant | General increasing bad state of the river; also as to barges and steamers being sunk. |
| C. Umfreville | Ingress Abbey, Greenhithe. | Gentleman | As to increasing bad state of the river in his neighbourhood. |
| William Lee | Manager, Messrs. Green, Blackwall. | Ship builders | As to the increased bad state of vessels they raise which have been sunk in the river between Blackwall and Gravesend. |
| Alfred Henry Keep | Greenhithe | Barge owner and freeman of Waterman Company. | Do. do. do. |
| W. H. Sandford | Gravesend | Trinity pilot | As to the foul state of the river when coming up with ships, and its increase. |
| Frederick Paterson | Do. | Do. | Do. do. do. |
| Charles Thomas | "Hercules" Dredger, Purfleet. | Engineer | As to increasing bad state of the river at Purfleet during last 15 years. |
| John Jewett | "Goliah" Dredger, Purfleet. | Do. | Same as last, but knew the river as pleasant before the outfalls. |
| James Perkins | Do. | Working hand | Same as last witness, but known river for 27 years. |
| Robert Grainger | "Cornwall," Purfleet. | Carpenter | On board 23 years. Notices absence of fish and bad state of the river since the outfalls; considers it to be rapidly increasing. |
| Francis Fitzgerald | Do. | Second Officer | On board 14 years; known river well 19; that water has got very bad since outfalls; attributes attacks of typhoid to state of river. |
| Captain Wm. Scott | 6, Hindon Valley Terrace, Sunderland. | Captain of the "Erith." | Engaged on river over 30 years. Notices increase of bad smells between Gravesend and Erith; suffers nausea at times; had boat sunk in Gravesend. |
| John Edwd. Waterson | 209, East India Road, Poplar, E. | Trinity pilot | Known river 30 years well; can speak as to increasing bad state, which is unbearable at times. |
| Benjamin Starbuck | 1, Swan Yard, Gravesend. | Fisherman | Cannot now catch where used to; has to go out seawards. |
| Samuel Grant | 1, Mermaid Court, Gravesend. | Do. | Do. do. do. |

The above list consists of all the further witnesses on behalf of the memorialists whose proofs of evidence have actually been taken, but we may mention that the memorial (a print of which is hereto annexed, with the names of some of the signatories) was signed by over 14,000 people, all of whom were asked at the time of signing if they were willing, and what sort of evidence they could give, and they all expressed their willingness to give evidence if amenable at the time of its being required. The solicitors to the memorialists could, if the Commissioners think it necessary, furnish a list of all the persons who signed the memorial, all which persons, it would be seen, are those who are affected by the polluted state of the river, such as shipowners, mariners, fishermen, watermen, &c., &c.

(B.) By the Erith Local Board and other Local Authorities.

Proofs of the Evidence of the following witnesses were taken by the solicitor of the Erith Local Board before and during the sittings of the Commissioners when they were taking general evidence. These witnesses were not, however, called by counsel of the Erith Local Board under the circumstances stated by counsel to the Commission at the Eighth Sitting, on Tuesday the 28th November 1882.

Yacht Owners and Membebs of the Corinthian Yacht Club at Erith and Captains of Yachts.

| Name. | Address. | Occupation. | Nature of Evidence. |
|---|---|---|---|
| T. Catter Gash - | Lower Park Road, Belvedere. | In Bank of England; Secretary of the C.Y.C. | Says:—Continual complaints made in respect of the foul state of mud and the impossibility of keeping yachts clean or crews healthy since outfalls opened. Has been affected many times by the bad smells from the mud, and says sewage is not carried away by the tide. That mud is covered by a black and filthy slime, and that sewage settles largely near Erith, and that there is no sign of a similar settlement in Sea Reach, at the Blyth Sand, which would be equally affected if the sewage passed it going out to sea. |
| S. Harman Sturgis - | 12, Copthall Court, Throgmorton Street, London. | Stockbroker; Vice-Commodore Corinthian Club; owner of yacht "Elsie," 35 tons. | Says:—Has been yachting for more than 15 years. Used to bathe off Erith, but cannot do so now from exceedingly putrid state of water. Smells arise from mud which are almost unbearable, and his captain, Henry Curtis, and men frequently suffer when off Erith from cholic and nausea, attributable only to impurity of the water, and smells from that and the mud, on which sewage settlement can be seen. |
| Geo. Wood - - | Coal Exchange - | — | Has been yachting on the Thames for more than 40 years. He well remembers the condition of the river before the outfalls were opened. The condition is considerably worse now than then, and has become of late years a disgrace to civilization. Is of opinion that the sewage deposits on the banks are on the increase and settling up. Finds the bottom of the yacht fouled with sewage. The steward of the Erith Yacht Club was ill in 1880, and was in Sussex County Hospital. Dr. Rutter reported he was suffering from mirage fever. During the time witness lived at Erith he noticed the stench at Crossness, and has sailed through a thick liquid sewage frequently. |

App. C.C.

| Name. | Address. | Occupation. | Nature of Evidence. |
|---|---|---|---|
| Landseer Mackenzie | 6, Kensington Park Gardens. | Owner of the yacht "Heathen Chinee." | Has been yachting on and off for 15 years. Has noticed the water in the river become extremely dirty towards half-ebb tide, and it continues to be so till after low water, with unmistakable evidence of sewage matter. Has also noticed unmistakable evidence of sewage matter deposited on the mud. The bottoms of the yachts rapidly foul in Erith Reach. Has frequently found a slimy deposit on the sides of his boat above the water-line, which it is difficult to remove. Speaking of the river generally, says that the flood tide is decidedly the strongest. There is an eddy in Church Hole, Erith, after half-ebb, so that the tendency of the current is up the river for about eight hours out of the 12. There is a distinct difference both in the colour and smell of the water from Crossness down to Erith compared with other parts of the river. |
| H. N. Custance - | 34, Tregunter Road, Brompton. | Owner of the yacht "Venture." | Has been yachting since 1867. Has noticed a great difference in the river since the outfalls have been opened. The water has a dark sewage aspect, and has a highly objectionable smell, with black looking particles floating about the surface. The banks of the river between high and low water mark are more or less poisoned. |
| J. D. Lee, Esq. - | The Oaks, Belvedere | Owner of the "Druid." | Has been yachting for about 50 years. Has remarked the state of the river, and has no hesitation in saying it has become worse since the opening of the outfalls. Lives about a mile from the outfall; has noticed the smells are much worse in hot weather. The deposits on the banks increase every year, and are most offensive, filthy, and black. The captain of the "Druid" complains of sickness arising from the stench. |
| John Fradgley - | Greenhithe - | Owner of the yachts "Honey Bee" and "Marion." | Has been engaged in yachting 40 years. Remembers the condition of the river before the outfalls were opened, since which time the water has become infinitely worse, and at times the stench is very bad. The banks of the river are very objectionable, and the sewage deposits have increased most perceptibly. Has found the yacht's bottom foul more rapidly owing to the foulness of the water. Great discomfort is caused to his crew through the condition of the river, but no positive illness. |
| T. G. Winser - | 72, Mark Lane - | Owner of the "Sheela," "Nellie," &c. | Has been yachting for about 10 years. The nuisance from the sewage is undoubtedly growing worse every year. The water is very foul, and bubbles up at low water. The smell is worse in warm weather. A boat will foul at Erith more in a fortnight than it would elsewhere in six months, owing to the state of the water. Has been unable to sleep on board at Erith owing to the excessive smell from the river, and it is generally most unpleasant to sail in Erith Reach in the summer from the same cause. |
| G. R. Dunell - - | 5, Eyot Gardens, Hammersmith. | Owner of the yacht "Gymnotes." | For some time lived close to Erith Church and almost within a stone's throw of the river, and observed the foulness of the water; the mud flats uncovered at low water are composed of a disgusting fætid slime that can be attributable to no natural cause of the river. So nauseating is the stench from the banks, and also from the water itself in hot weather, that, as a rule, it is impossible to take any pleasure afloat in the summer. His yacht, although a fast steam launch, fouled rapidly off Erith, far more so than at any station out of the Thames. The evil state of the Thames increased year by year up to 1878; 1879 was a favourable year. Since then has abandoned the Lower Thames as a pleasure resort. |

| Name. | Address. | Occupation. | Nature of Evidence. |
|---|---|---|---|
| Stanley A. Hicks - | South Lea House, Datchet. | Owner of the yacht "Rifleman." | Has been yatching for about 10 years. The water off Erith is in a very turbid condition, especially at low water. It is worse on warm days, and has often noticed a smell from it. Finds his yacht's bottom fouls very quickly, which he attributes to the foul state of the river. Although none of his men have been ill, has had complaints as to the smell of the water from them. |
| E. B. Tredeven - | 27, Walbrook, E.C. | —— | Has been yachting on the Thames since 1872, a good deal in canoes, so that the condition of the water was brought forcibly to witness's notice. There has been a decided change for the worse in the river since 1872. The water is strongly impregnated with sewage, and cannot be bathed in without making one sick, and the banks are covered with foul smelling slime or mud. On warm days the smell is much worse. The mud deposits on the banks have become much more objectionable, because so largely mixed with sewage; very foul gases escape. On one occasion, at about one-quarter ebb, paddled close under the Crossness outfall, and was so sickened by the sewage then that had always endeavoured to give it a wide berth since. Has often seen excrementa floating in considerable quantities on the tide. |
| William Cook - | —— | Captain of the yacht "Marana." | Witness was formerly steward of C. Y. C. at Erith, and lived with wife and three children at club house there. His wife and children were never well, and the youngest died. He then gave up situation, and became captain of the "Marana." Has almost continually through the last two summers slept on board yacht off Erith, and during that time has suffered from chronic diarrhœa and cramp pains, which he attributes to sewage. In hot weather sewage lies on surface like dirty grease, quarter inch thick, and the stench is horrible from it. It clings to the boats and spoils the paint; smells like a cesspool, and cannot be used, except just at high water for washing decks. Witness says stream is silting up through sewage deposit and nothing else, as the black deposit is not river mud, to which he has been used from his infancy. Witness says yacht owners are removing their yachts from Erith to the mouth of the Thames, to avoid the dreadful sewage stench. |
| H. Curtis - - | —— | Captain of yacht "Elsie," 35 tons. | Supports generally the proof of evidence of W. Cook and the evidence of J. G. Lee given before the Commission on the fifth day of sitting, page 17, and has suffered from sore throat and sickness, attributable to sewage pollution. |
| J. Brown - - | —— | Captain of yacht "Irene." | Do. do. |
| H. Eagle - - | —— | Captain of yacht "Little Emily." | Do. do. |
| A. French - - | —— | Captain of yacht "Venilia." | Do. do. |
| John Cornish - - | —— | Captain of yacht "Lolah," 20 tons. | Do. do. |
| Wm. Spooner - | —— | Captain of yacht "Challenge," 20 tons. | Do. do. |
| Adolphus Rand - | —— | Captain of yacht "Maritana," 20 tons. | Do. do. |
| Albert Rouse - - | —— | Captain of yacht "Primrose," | Do. do. |
| Thomas Barnard - | —— | Captain of yacht "Wenonah," 36 tons. | Do. do. |
| James Barnard - | —— | S.S. "Reseda," 25 tons. | Do. do. |
| H. Cook - - | —— | S.S. "Kitiwake," 20 tons. | Do. do. |
| F. Prizeman - - | —— | S.S. "Mascota," 14 tons. | Do. do. |

App. C.C.

| Name. | Address. | Occupation. | Nature of Evidence. |
|---|---|---|---|
| | | General Witnesses. | |
| Robert Stone - - | 40, Pier Road, Erith | Barge owner - | This witness can speak as to the state of the river both before and since the outfalls, how it has become polluted by the sewage, and is so foul now that it quickly spoils the paint on the barges, and makes the ropes and anchor chains smell horribly, that the sewage settles on the banks and the bottom of the river in large quantities, and is forming in Erith Bight and other places banks of corruption. |
| Samuel Chittenden - | 53, Pier Road, Erith | Gentleman - - | This witness confirms generally the above statement. |
| Jonas Watts - - | Metropolitan Police, Erith Section, R. Division. | Coroner's Office - | Do. do. |
| Walter Ponting - | Do. | Do. - | Do. do. |
| Thos. W. Spencer - | 1, Yew Tree Terrace, Erith. | Master Mariner - | Do. do. |
| Wm. Jas. Young - | Cambridge Hotel, Woolwich. | Retired Master of London Steamboat Company. | Do. do. |
| John Pain - - | East Greenwich - | Bargeman - - | Do. do. |
| Robert Andrew Gibbons. | Of firm of Robins & Co., Northfleet. | Cement Manufacturer. | Do. do. |
| | | Captains of Barges. | |
| W. Richd. Stratfield | 5, Northfleet Creek, Kent. | Captain of barge "Ann Corsan." | Says:—Knew river before outfalls were erected. Then water and mud both pure; now it is poisoned, and river is silting up everywhere with a filthy deposit from the sewage outfalls, which settles on the bottom of the river, and which smells horribly, especially on the chains and anchors. The smell from the river water and mud makes witness heavy and drowsy, and causes loss of appetite, and he says nuisance is steadily increasing. |
| Lewis White - | 7, Grange Road, Plaistow. | Captain of barge - | Can confirm generally above witness. |
| Henry Tyler - | 2, Church Terrace, Grays. | Do. - | Do. do. |
| Alfred Cattaway - | 53, High Street, Grays. | Do. - | Do. do. |
| William Stowers - | 3, Brunswick Road, Gravesend. | Do. - | Do. do. |

FISHERMEN.

| | | | | |
|---|---|---|---|---|
| John Beichteller - | 97, West Street, Gravesend. | Fisherman, 60 years old. | | Says best fishing ground before the sewage outfalls was between Woolwich and Gravesend, especially off Erith, where fish were caught in great quantities. The sewage quickly poisoned the water, and has by degrees driven all the fish out of the river. The sewage outfalls have also so polluted the bottom of river that impossible to move a net along it now from the stinking sewage matter there. That before the outfalls opened the mud was a bright, clean, healthy mud, full of fishes food. That the evil is increasing every year, and generally witness can confirm Mr. Cobb's evidence given before Commission on the third day, page 25. |
| James Moore - | Melbourne Place, Gravesend. | Fisherman, aged 67 | | Can confirm above evidence. |

# DIGEST.

MR. CHARLES BEADLE, Member of the Firm of Beadle Bros. of Erith, and Commissioner for the purpose of maintaining the river wall.

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Has known the river about 35 years, and has spent a great deal of his time on it, 225, 229, 250, 373, 309. When first he knew it, the water was clear and wholesome, 227, 228. People used to bathe at Erith, 233–4, but do not do so now, 419–22. Since the outfalls were made the river has been growing gradually more dirty and objectionable. At first the river was not charged with sewage, 234–5, 240, 378–9. Coming up from the Nore, the water first gets thick in the Lower Hope, and gets worse until the outfalls are reached. It improves as you get to Greenwich, and is tolerably clear at London Bridge, 253.

OFFENSIVE ODOURS.—In hot weather there is a very disagreeable smell which has got much worse within the last few years, 241–3. It is worst between Blackwall and Greenhithe, 254, and is more noticeable from half ebb to half flood tide, 257, 345–6. The water becomes black when the sewage is discharged into it, and in hot weather gas bubbles may be seen rising near the shore which emit a disagreeable odour, 255–9, 401–2. The mud of the river, which formerly was dark clay, is now black, and is so offensive that his workmen, of whom he employs between 200 and 300, 367, object to work on his vessels at low water, and make constant complaints of the smell, 260–7, 411. Has experienced it himself, and in hot weather it produces headache and nausea. It is decidedly a sewage smell, 301–6. There are no worms to be found in the mud now, 266–7. When the wind is blowing from the north, a great nuisance is caused by the smells from the different works and factories on the north side of the river. They are of a most offensive character, but are easily distinguishable from the smells from the river. Has detected smells from the factories at his house, which is three miles from the river, but never the sewage or mud, 348–63, 404–8, 418. The water gives off a disagreeable smell, which can be detected when on the river, 342–4.

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—Sewage matter has accumulated on the south side of Erith Bay during the last 20 years to a height of from 10 to 12 feet, but not on the north shore. It has increased more rapidly during the last 10 years, and is exposed at low water 150 feet further than formerly, 280–82, 311, 325–31. A buoy which floated at this place in 8 or 10 feet of water is now out of water at low tide, 283. The sun causes the exposed deposits to decompose and give off a gas, which is what he suffers from most, 288–90. The deposit is diluted sewage, 403. The stone causeway at Erith has been lengthened several times within the last 20 years to an extent of 100 feet on account of a deposit of black slimy mud around and over it. Now a floating causeway has been placed there, 291–5, 307–8. Has been obliged to keep a gang of men to flush the foreshore in order to keep it clear of deposit for the last two years. One man was sufficient for this purpose formerly, 425–32. The character of the mud has completely altered, and he has brought samples with him for analysis, 332–4, 434–5.

INJURY TO FISH.—When first he knew the river, the water was clear and wholesome, and twenty years ago fish could live in it, 227, 228. Has caught fish at Erith as recently as 10 years ago, 231–2, 238. It was a good place for fish, 239. Now all the fish are driven down as far as Sea Reach from Blackwall, and year by year go farther away, 245–52.

SET OF THE TIDE.—An empty dummy barge would drift with the tide from Crossness outfall to about Gravesend Reach, according to the strength of the tide. It would drift up further than the point it started from, 274–9. In Erith Bay the tide causes a back-water round the point, making an eddy strong enough to turn a boat's head up the river, 285–7. The

MR. CHARLES BEADLE—*continued.*

SET OF THE TIDE—*continued.*

tide goes from point to point, and does not sweep round the points more since dredging operations were commenced to remove the shoals, 313–20. There was always slack water at Erith Bight, 322. The low-water mark has advanced 150 feet further towards the middle of the river, 296–300, 307. The removal of the tongue at Coldharbour Point has not influenced the set of the tide above it, nor has it altered in the eastern part of Erith Reach, 323–4, 381–92. Vessels going up or down at this part keep well out in the stream, and go from one point to the other, 381–98.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—Believes Erith has a lower death rate and is more free from zymotic diseases than most places, but the smells from the river and deposits affect the health of his workmen, and there has been more sickness amongst them during the last three years than before, 369–74, 376, 411.

MR. JOHN ROBERT BUSBY, Trinity House River Pilot, 59, Parrock Street, Gravesend.

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Has been on the river for 40 years, and a pilot for 21 years. When first he knew the river, the water was clear, and very clean. It was always used for drinking and cooking purposes on board ship, both by passengers and crew, 436–42, 484–86. It began to get foul in 1855, and got worse each succeeding year, owing to the number of outlets from Jenningtree Point to Blackwall, 443. It is not so foul in wet summers, 444–5. In 1858–9 the water from Woolwich to Westminster was in a dreadful condition, 476–9, 513–15. In Long Reach the water is better, 447–9.

OFFENSIVE ODOURS.—From Erith to Woolwich the water is in a most offensive state, and when a ship is being towed up or down the smell is unbearable. The decks cannot be washed down with the water, as it is filthy and black as ink. Considers the river between these points to be most obnoxious, and it is a huge cesspool, 446. It is worst on a summer morning early, after dry weather, at neap tide. Has had to keep his handkerchief to his nose for an hour at a time, 470–71, 517, 523–4.

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—At Erith has noticed slush (which has come out of the sewer), deposited on the shore nearly ankle deep, 453–9. It has increased during the last 10 years on both sides of the river, viz.:—at Erith and Rainham Bight, 507–8, 525–7. The sediment is deposited on the bed of the river, but the dirty water comes back. Has seen a circle of black matter at high tide extending a mile from the outfall, 466–7.

SET OF THE TIDE.—The tide sweeps from bight to bight, 460. Before the dredging was begun, there was scarcely six feet of water at Cold Harbour and Rand's Hill, and has seen smacks run aground there. Does not think that the set of the tide was affected by the removal of the point, but it may run faster, 489–503. There is more water now, owing to the dredging, and vessels can go over the place where the shoals were, 504, 510–12, 522. The water is slack in the middle, and slacker on the north shore than on the south, 528–30. It is not slacker than it used to be, 531. Sewage discharged just after high water at Crossness would drift down to Gravesend with a spring tide, but would not be so obnoxious there as at Barking or Crossness, as the water has become more mixed with it. On a neap tide the drift would go as far as Greenhithe. It would go up as far as Greenwich, 461–6.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—Attributes his own good health and appearance to steady habits, 482–3.

INJURY TO FISH.—Fish used to be caught between Barking and Erith 30 years ago, but is unable to say when they ceased to be caught at Erith, 472–5.

## Mr. WILLIAM SANDFORD, Shipowner, Tudor Lodge, Gravesend.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river for 45 years, 28 years of which he was a Trinity Pilot, 534–6. Before the outfalls were opened, the river between Jenningtree Point and Blackwall was in a very foul state. It extended even to London Bridge, 540–4. From Jenningtree Point to Gravesend the water was not affected by sewage, 545. After the opening of the outfalls in 1864 the river for four or five years was fairly clear between Crossness and Gravesend. Since then it has gradually got bad, and now is in as foul a state as it was originally, 546–8. It is worst on neap tides at low water, for tugs and steamers stir it up, and make the water quite black. After heavy rains it is not so bad, 549–52. Recommends that the sewage be carried to the east shore of the Lower Hope below Gravesend, 647a.

Offensive Odours.—There are a great number of offensive smells on the river between Erith and Crossness, but in particular between Jenningtree Point and Crossness. Has noticed the smell from the factories which are higher up the river. The smells are noticeable always on the last of the ebb when navigating the river, 630–47.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Has noticed the accumulation of mud on the banks at Crossness. Formerly there was anchorage in 14 feet of water at Tripcock Point, and now you cannot approach it. At low water in other places there is not more than eight or nine feet of water where there used to be from 14 feet to 15 feet, 553. The deposit has been much greater during the last 10 years, 554. From Jenningtree Point to Erith the deposit has increased rapidly, 555–61. It is of a very offensive nature, 612–17.

Set of the Tide.—The ebb tide sets from Jenningtree Point (down Erith Reach) over to Cold Harbour Point. Except on the first flood, there is little strength in the tide between Church Hole and Erith, 562–70. A vessel drifting down would not go into Erith Bay on account of the slack water, 571–6. Has proved by an experiment that while the last of the tide is running down there is an under-current running up which he believes to be the young flood. It is perceptible one foot from the bottom to about six or seven feet from the bottom, 577–84. This under-current stirs up the deposits from the outlet at Crossness, 585–8. Sewage matter discharged at high water on a spring tide would not go below Purfleet, or at all events not below Greenhithe, because the body of a man drowned at Crossness is never picked up below Purfleet, 590. On a neap tide it perhaps would reach Erith, 591–2, 626–9.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The smells arising from the river have not affected his health, though he has experienced a choking sensation, and a desire for fresh air when passing through this bad part of the river, 593–4, and would watch the time to avoid the smells, 595.

Injury to Fish.—Remembers fish in the river between Woolwich and Gravesend, though none have been caught for 12 or 14 years, 596, 602, 603. Whitebait was caught at Blackwall, and salmon and sturgeon below Woolwich, 604–7. Fish brought up the river in wells from Iceland would live at Gravesend, but now they would die if kept there, on account of the polluted state of the water, 596–601, 608–10, 618–21. Last summer a salmon was caught between the Nore and Gravesend in a net, 622–5.

## Captain ARTHUR MORREL, R.N.

### Training Ship "Cornwall."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been in command of the "Cornwall" for nine years. She is lying at Purfleet, 648-51. Has known the Thames for over 20 years, and the water was used for drinking purposes when he first became acquainted with the river, 652–6. Of late years the river has become very impure from matter discharged into it, 659–61. Used to wash the ships' decks with river water, and the boys bathed in it; but has discontinued the practice for several years on account of the sickening smell which it emitted, and now uses fresh water, obtained from the Grays Waterworks for this purpose, 662–70. Used to bathe in the river over 20 years ago at Erith, 657-8.

## Captain ARTHUR MORREL—*continued.*

Offensive Odours.—The smell from the water has been getting gradually worse every year, 686.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Owing to his duties on board the "Cornwall," he has not had much opportunity of noticing the deposits of mud on the river banks, 687.

Effect upon Health in the Neighbourhood of the Main Outfalls.—There are on an average from 200 to 250 boys on the "Cornwall," 674. In 1875–76 a severe epidemic of typhoid fever broke out, and in consequence he discontinued to use the Thames water, 671–2. Since doing so, the percentage of illness has been less, 673–5. Since leaving off the water there have been no epidemics of typhoid, though there have been isolated cases, 676–84. Attributes a feeling of sickness which he experiences in the morning to the smells from the water, 685. There was an official inquiry into the health of the boys, especially with reference to the prevalence of enteric fever amongst them in 1878, 688–93. Denies the statement made by the medical officer in his report, that there is great freedom from serious sickness, and that minor ailments are rarely troublesome, 695. Extracts read from the report of Mr. Netten Radcliffe with reference to the outbreak of fever, the discharge of sewage from the outfalls, its distribution, &c., 701–7. Denies that fever or illness can be brought from the shore, as all the boys when they arrive on board are in good health, and are certified by the surgeon of the gaol from whence they come to be so, 708–10, 715. No serious illness has occurred to any boy immediately on arrival. He would have been some months on board at least, 710, 715–17. Has not noticed much smell arising from gases emitted from the mud when the ship's keel has touched the mud at low water; indeed, he believes the bed of the river under the "Cornwall" to be nearly free from deposits, 713–14. The cause of the outbreak of fever is not really known, nor could it ever be clearly proved, 723–4. The report of Dr. H. Leach, medical officer of the Port of London, dated 12th November 1875, referred to by Mr. Netten Radcliffe (Qq. 702 and 718), on the typhoid epidemic on the "Cornwall," was put in and read, 861–3. Extracts from a report to the Local Government Board by Mr. W. H. Power, dated 15th March 1880, on the outbreak of typhoid in 1878, were read, 864–76. From that report it appears that the cause of the outbreak was suspected to be due to the presence of trichina in the pork eaten by the boys, 877–9. Application was made to exhume the body of the boy who died, and on making a microscopical investigation of the abdominal muscles a living *trichina* was discovered, while traces were found of the presence of others which were dead. Dr. Power holds that this proves most conclusively that the boy died from trichinosis and not from typhoid fever, as stated at the post-mortem examination, 879–82. Professor Cobbold did not believe the animal or specimen to be the real trichina, 883–4.

## Captain FREDERICK WALTER, R.N.

### Training Ship "Arethusa."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is in command of the "Arethusa" stationed off Greenhithe, 725–727. Has been in command for eight years, and did not know the river before, 729. It has been getting worse each year, especially during the last four years, 730–732. In hot weather and at low tide it is worst, and has noticed smells arising from it, 746–7. The boys bathe at the top of high water only, 754–5.

Offensive Odours.—Smells are noticed principally at low water, and believes the worst smells arise from the mud, 756, 758–60. They are more noticeable when the water is stationary than if it is running, 761–2. In hot weather the smells are very bad, and the mud on the banks smells both at high and low tide, 785–6. The Canton River and the mud in it are both offensive 788–91.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Can see the mud on the banks from the ship, though he is unable to say whether the deposit has increased of late years, 748–9. Is about eighty yards from the low-water edge, 752, and about 150 yards of mud are exposed, 757. The colour of the mud has not altered during the last eight years, 750–1. Has had no experience of Thames mud at any other part of the river, 787.

## Captain FREDERICK WALTER, R.N.—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls.—There was an attack of typhoid fever on the ship in 1879–80, 738, 777. It lasted nine months, 778–9. An enquiry was made into the origin of the outbreak, but never discovered the cause, 781–2. The decks were washed with Thames water prior to the outbreak of fever, but on discovering that it smelt very badly if it remained on the deck, the practice was discontinued. The water was very dirty and impure. It is still used for washing the upper deck, 739–45. The general health of the boys is very good; since the fever there has been less serious illness than before, and there has been no typhoid since discontinuing the use of Thames water, 765, 794–7. Two boys died in 1881, one of consumption, the other from an affection of the lungs, 767, 770–1. It was certainly not due to the water or the smell, 772. The year before there were two deaths, 773. There are 313 boys on board, and their age on entering varies from 13 years to 17 years, the average age is 15 years, 776, 768–9.

Injury to Fish.—Until four years ago boats used to come up to Greenhithe to fish for shrimps and dabs. There have been none since, 733–6.

## Captain ARTHUR GILLETT, R.N.

Training Ship "Warspite."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been in command of the "Warspite," which is stationed off Woolwich, nearly five years, 798–800. The state of the river has not varied (though just now it is very clear), 801–3. Generally in July it is very bad, the water becomes slate-coloured, and great masses of black mud come up from the bottom which spread over the surface, 804–6, 860. In winter the river water is used for washing the upper deck and kitchen utensils, but never in summer, because of its bad state, 819–22. Samples of water taken from mid-stream at low ebb, opposite the ship, on being analysed, were reported to be "slightly diluted sewage," 814–17, 857.

Offensive Odours.—The smell from the river in summer is dreadful, and the ports have to be closed; the deck under the hammocks being kept wet with disinfectants for about a month, 806–10. It is equally bad at all times of the tide, 811. If anything, last year was the worst, 812. Has smelt the mud 30 feet above the level of the water, 846. The river mud at Woolwich does not smell, 842–5. There is no mud bank near the ship: it is washed away, 847–8.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—On one of the mooring chains parting last year it was discovered that it was covered with sewage, 813, 837, 858–9. When the river becomes slate-coloured the oars and blades turn black, 804, 825. The floating particles of sewage sink and are deposited at the bottom of the river. The whole bed of the river, he believes, is nothing but sewage. When the temperature rises the gas explodes and great masses of black stuff come up and spread over the surface, 828–36. Is not aware that black matter accumulates at the bottom of ponds into which no sewage is discharged, 839–41. Steamers passing at low-water stir up the sewage, 830.

Set of the Tide.—Does not know the operation of the tide above and below the "Warspite," having only a general knowledge of tides, 813. Sewage discharged at high water would drift about fifteen miles on the ebb. It certainly comes up to Woolwich from Barking and Crossness, 826–8.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Every year there have been isolated cases of typhoid fever which can only be attributed to the state of the river, 818. There are 200 boys on board, and they are remarkably healthy. There is no sickness at present. The average age of entering is 15, 850–5.

## Mr. WILLIAM EGERTON, Belvidere.

Surveyor to the Erith Local Board, and Inspector of Nuisances.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has lived at Erith for 21 years and at Belvidere for 5½ years, and has known the river all that time, 895–900. Since the opening of the outfalls there has been a very great alteration in the river. The discharge from the sewers can be distinctly seen and traced down to Erith by the different colour. Below Erith he does not know the river, 912–5. There is a discharge from Price's oil factory into the "common sewer ditch" (which is really a marsh drain), and which flows into the river, 949–50, 983–9. The ammoniacal liquor from the gas-works is put on barges and taken up to London. There is no discharge from these works into the drain or river, 4295–7.

## Mr. WILLIAM EGERTON—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

Offensive Odours.—There is a very bad smell at times from the water, like that from a recently emptied cesspool, and especially when the wind is off the river. It is worst in warm weather, and at half ebb tide, 917–20. As inspector of nuisances has visited the factories on the south side of the river situated for the most part between Jenningtree Point and Erith. Offensive smells come from most of them, and he can distinguish the various smells. They are entirely different to the smells from the river, 921–948. The smells from the factories on the north side are also different to the river smells, 951–2. With a hot sun, and the wind off the water, the smell from the mud is nauseous and very unpleasant. The factory smells can be avoided, but you cannot avoid the river smell, 976–7. It arises from both the river and the mud, 1006–7. Of the two would prefer the smell from the factories, 1008–16. It has been worse during the last five or six years, 1033, and the smell can be noticed from Jenningtree Point (Johnson's works) to beyond Erith on the road to Crayford, 1035–6. With westerly winds it is not so noticeable, 1037–43, 1057–8. It varies according to the direction of the wind, and the state of the weather, 1059–62. In the spring of 1882 he received instructions to specially inspect, with Mr. Ogston, the factories on account of complaints being made by the inhabitants of Erith that the smell was a nuisance. The complaints were well founded, and alterations had to be made in the machinery, &c. Since then an inspector of factories has been appointed under the Alkali Act, and the nuisance is less, 1063–74, 1078–85.

Wishes to correct a statement about the position of Jenningtree Point (Q. 934). He thought it was higher up than it really was, 4156–7. Is of opinion that there is more nuisance caused by the smell from the accumulation due to the outfall than there is from the discharge of sewage at Erith, 4208. Has frequently been consulted as to steps to be taken with regard to nuisances arising from the smell or other causes from the factories at Erith, regarding which complaints have been made, 4213.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There has been a considerable alteration in the low-water mark during the past twenty years. Two buoys for moorings put down in nine and fourteen feet of water at low water respectively are both now frequently aground. The water recedes some yards from the first buoy. They have never been moved, and vessels cannot swing at the buoy, 901–11. There has been an increased deposit of mud at Erith on the banks in this time, and the colour is much darker. There is much more of it also, 969–72, 974–5. Just above Church Hole between half ebb and half flood vessels swing round the reverse way to what they would in the stream, often fouling their anchors, 973. There are no sewers where the mud lies thickest. Where the largest sewer discharges there is less mud and filth. The deposit is thickest opposite the two ballast wharves, 4183–6.

Set of the Tide.—From Crossness, the sewage discharged at the top of the ebb tide would for the most part go down the centre of the stream to Erith. Below that point can give no opinion, 965–8. It is to be distinguished by the colour and the "streamage," or corks, &c., which go along each side of it, 1044–8. The discoloration extends over about one eighth part of the river, and the smell can be detected from the banks, 1044–56.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The smells arising from the river, and living so close to it, affected the health of his wife to such an extent that he had to change his residence eight years ago, 978–82. His house is now 170 feet above high-water mark, 1075–6. The smells have not affected his health since he removed to higher

Mr. WILLIAM EGERTON—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

ground, 1077. Erith is as healthy as the surrounding districts, and the death rate is below the average, 990–1, 995. The high land is much more healthy than near the river, and the only case of typhoid fever as reported in the latest return of the medical officer occurred on the high land, 996–1000.

Injury to Fish.—About 24 years ago there used to be fish in the river at Erith, and he recollects the Dutch eel boats coming up until nine years ago. They discontinued doing so, as the fish could not live in the water there, owing to its impure state. Some eels were picked up on the mud three years ago in a dying state, 953–64, 1001–5.

Petitions, Inquiries, and Reports on alleged Nuisances.—In consequence of a petition presented to the Local Board, steps were taken to inquire into the nuisances caused by the factories in 1880, and Mr. Ogston, a professor of chemistry, was employed by the Board. In 1881 he (witness) reported to the Board that a serious nuisance was caused by the offensive state of an open ditch at the back of Messrs. Price's works, which produced offensive smells. This ditch had an outlet into the Thames. Within the last two years has been called on to visit and report on several factories which have been complained of as nuisances, 4216–36. There is no other factory which discharges refuse into the Thames, 4236. About November 1881, presented a report to the Board, on the works of Messrs. Price, Messrs. Callendar, Messrs. Berger and Spence, and Messrs. Collins. From Messrs. Collins' works has found stagnant water and offensive matter flowing from the hides and material on the river wall into the river, 4246–54. The Erith Local Board prosecuted a firm for landing particularly offensive manure at a wharf in Erith, which was a nuisance to the inhabitants, at which prosecution he gave evidence. The cause of the nuisance was due to their letting the manure remain on the wharf longer than was necessary. Complaints had been made on previous occasions as to the smell, 4237–45.

Population of Erith.—There has been a great increase in the population of Erith during the past 17 years to the extent, he believes, of about one-third more, 4287–8.

Drainage of Erith.—There are 1883 rateable houses in Erith, 507 of which are drained into the Thames, and 1,376 drain into cess-pits. For the purpose of draining those 507 houses there is a public sewer with a 15-inch iron pipe at the outlet which runs into the Thames off the South-eastern Wharf. Another goes from the Bexley Road across the High Street into the Thames with a 12-inch pipe, opposite a beershop kept by a man called Wiggins; and there is a branch 9-inch pipe which comes down Cross Street and discharges close by the flour-mills, a little above the causeway, 4158–69. The main sewer pipe runs into the river about 80 yards, but does not extend to low-water mark, 4187–9, 4194–206. Does not know how many houses it drains, 4212. The houses which drain into this sewer are for the most part cottages and modern houses. Those which drain into cesspits are mostly old houses, 4283–6. There is a 6-inch outlet from the works of Messrs. Shuttleworth & Chapman, and these are all the sewers he knows of which discharge into the Thames, 4170–6. The cesspools are self-contained, and have no overflow, 4190–3. The contents are emptied by farmers and put on the land. Slops go into them, and if the pits are made in the gravel, they are to a certain extent porous, 4289–94. Assisted a Committee of the Board last year in investigating the question of the factory nuisances, but has not been so engaged this year, 4259–61. The new Act came into operation on the 1st of January, 4262. Has served notices on inhabitants to abate local nuisances, but is unable to remember the particulars, 4263–9. There are two manure works at Belvidere, but has not visited them this year, nor is he aware of any complaints being made respecting them this year. Mr. Ogston has not been called in to report on them, 4270–2. Notice was given to Messrs Price and Company last year, to abate the nuisance caused by a ditch, which has been cleared out, 4273–6. Since inspecting the factories and serving notices on the firms the smells from them have been very much better, 4277–80. Makes reports to the Board after visiting the factories from notes which he makes, but keeps no diary, 4298–300. The gulleys which take the surface water from the roads are attended to from time to time. It varies from a week to a month according to the state of the weather whether wet or fine, 4178–81.

Mr. WILLIAM EGERTON—*continued.*

Drainage of Erith—*continued.*

Proposed Drainage for Erith.—About four or five years ago, Mr. Edward Easton was called in to prepare a scheme for draining Erith, and he reported on the state of the drainage, 4209–11.

## Mr. MICHAEL HIND, Erith.

Auctioneer and Undertaker. Member of the Local Board of Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is 54 years of age, and has lived at Erith all his life, 1088–9. There have been great alterations in the state of the river during the last twenty or thirty years, since the opening of the outfall, 1090–2. It was much purer, and there was not so much sediment. The sewage in the river increases every year, 1093–5. Remembers the river water being used for drinking purposes fourteen or fifteen years ago towards the Pool. The ships used to fill up their breakers in the Pool, and take it to sea. Off Erith it was used for culinary purposes, 1096–9. At high water off Erith the water would be (at that time) a little brackish, but not at low water, 1100–1. Has oftened bathed in the river, but would be sorry to do so now, 1143–5.

Offensive Odours.—Has noticed a very unpleasant smell coming from the river which resembles the smell of a cesspool recently opened, 1116–7. It has not been so bad this year, because the summer has not been so hot, and there has been also more rain, 1118–9. It is most noticeable in hot weather, and when the wind blows from the north to east, especially in foggy weather, 1120–1. The mud on the river banks has a very offensive smell, which is much worse than it used to be, 1147. The smell which comes from the factories is very different to the river smell, and people who have lived any length of time in the neighbourhood can detect the difference directly, 1147–9. The smells from the factories on the south side are not alike, and he can distinguish between them. They are all unpleasant, but none are so bad as the river smell, 1150–8. The north wind brings the smell of the factories on both sides of the river to Erith. Is not acquainted with the factories on the north side, and cannot distinguish the smells from each as he can on the south side, 1163–76. The works on the north side are not opposite to Erith, but are two miles or more further up the river, 1177–83. Directed an enquiry to be made into the complaints of smells from the factories within his jurisdiction a few months ago, 1184–90. If the Commissioners or the examining counsel would only go to Erith, they would be convinced of the reality of the smell from the river, 1204–5. It is more noticeable when the wind is light than when it blows hard, and in foggy rather than bright weather, 1206. The smell of the mud is totally changed since the outfalls were opened, and increases continually, 1213–15. Has not conferred with the Inspectors of Nuisances on the evidence they were going to give, nor agreed as to what they should say, 1160–61.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Lives exactly on the causeway, which has had to be lengthened more than 100 feet, and raised more than three feet, owing to the deposit of mud which entirely covered it, 1102–6. Its present length is over 400 feet, and before being lengthened there used to be 12 or 13 feet of water at the end, in which a large yacht drawing ten feet of water could swing, without grounding, within twenty feet of the causeway. Now that part is quite out of water and dry at low spring ebb, and there are thirty feet of dry bank at the end of the causeway, 1107–8. The deposit has been accumulating since the opening of the outfalls, and increasing gradually year by year, 1109–10. The causeway this morning at 8 a.m. was covered with black stinking mud. At the end there is at least ten or eleven feet perpendicular of solid mud, 1111–15. Remembers the accident to the steamer "Princess Alice," which happened at Tripcock Point, just above the northern outfall between North Woolwich and Halfway Reach, 1127, 1130–1. Of the twenty-nine bodies which he saw brought ashore at Erith, those which had been in the water three or four days were in a dirty filthy state. All their underclothing was

Mr. MICHAEL HIND—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

saturated with "perfect muck," and their clothing was in an exceedingly dirty state, which gave off an offensive smell, 1128–29, 1132–1136. Before the outfalls were opened, bodies drowned, and the clothing, were in a much cleaner state, 1137–42. There is a very great difference between the mud on the banks before the outfalls were opened and the present time, both in colour and quantity. Years ago the mud at the edge of the river was much lighter in colour and only ankle-deep. Now it would be up to your waist and most offensive in smell, 1145–7. Inshore in Erith bay there is a large amount of mud which has reduced the strength of the tide considerably. It causes an eddy also which extends from below Church Hole to below Easton and Anderson's Works, 1199–1203. The accumulation of mud is not in any way due to the causeway, because the mud is on both sides of it, but more on the side nearest to the outfall. It cannot be said to be a breakwater, as part of it is on piles, and there is a large amount of deposit three hundred yards from the causeway around the wharves and piers, with nothing to prevent it being washed away; and gangs of men are kept for the purpose of washing and flushing it into the stream, 1207–12.

Set of the Tide.—There is a very great change off Erith now as regards the current. It is further out in the stream than it used to be, and the ebb just after high water goes from angle to angle, 1191–5. There is not so much current now as there used to be, owing to the accumulation of mud, though it takes the same direction, 1196–8.

Injury to Fish.—A great many fish used to be caught off Erith before the outfall was opened, between Church Hole and Rainham Ferry, also in Aveling Bight near Purfleet. None have been caught there for eight or ten years, and the boats have gone down lower and lower, until now they have got to Lower Hope, 1122–6.

Mr. WILLIAM COBB, East Greenwich.

Fisherman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is 75 years of age, has been engaged in fishing for 60 years, and is the oldest fisherman on the Thames, 1216–18. Has known ships take water out of the river at Deptford and Blackwall for drinking purposes, and has drank the water himself. It was clear beautiful water then, but he would not do so now, 1240. It stinks now, and is of different colours, according to the way the stream is running. As for the bottom, a pole would stand in it, and the pole when pulled up smells worse than any closet. (*Exhibits signs of disgust.*) 1240–4. The Dutch eel boats which used to go up the river on the neap tides are now obliged to pack the fish in boxes and send them quickly up to London from Holy Haven (seven miles below Gravesend) because they cannot take the fish through the sewage water. Has experienced this himself, as, if left in the well, the heads of the eels would swell, and they would be of no use. If an eel is put into sewage water, it kills it at once, 1269–73, 1275. Is obliged to take the boxes up from the river at Gravesend, and place them in the boat, and they cannot be put into the river again until the Pool is reached, 1274. Has not noticed any "scum" from the factories on the river of any consequence, 1333. The "skimmage" of the tide between high and low water, wherever it pitches, is known as "scum froth." It has an oily appearance, and does not kill the fish. Does not remember grumbling at any discharge from the factories, 1332–41, 1417. Has seen fish killed by the discharge of sewage from the outfalls in various reaches, 1342–9. Has seen the discharge of sewage many times. It continues from the ebb tide until the flood tide stopped it; that is from about two hours and a half after high water until about two hours before high water, or from half ebb to half flood. This happens every day, 1281–83, 1371–86. As much sewage flows out upon the flood as upon the ebb, and has seen it this year at both the outfalls, 1387–93. There are no worms in the mud now, which is quite different to what it used to be, 1416. A meeting of fishermen was held at the "Golden Anchor" about a week ago, at which the evidence to be given was discussed, and the men were asked to attend. Witness, as the oldest hand, was asked to collect evidence, 1353–69.

Mr. WILLIAM COBB—*continued.*

Offensive Odours.—The smell from the mud at the bottom of the river is very strong, and is worse than any closet, 1243–4. Could prove it if anyone present went down the river in his boat, 1262. Has noticed a smell from the factories, but not like the river, 1329–32.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Ever since the outfalls were opened the fishermen's nets, when taken out of the water, are corroded with all manner of filth, and they could not get them clean if they were to put them in now, 1236–8. The causeway at Erith has been lengthened several times on account of the accumulation of mud, and there is now at least 12 feet clear settlings of all kind of mud there, which is caused by the tide coming round the point, 1245–6. At Church Hole the bottom used to be hard gravel bottom, but now it is covered with a black filthy sort of mud, which increases every day, 1247–54. A fresh in the river would make a slight difference by washing a little of it into deep water, 1255–6. Thirty years ago the mud at Erith was the same as is now to be found in the Medway. It had a bright colour (whitey-brown), full of red worms, which were good for bait. There are no worms now at Erith, 1257–61, 1394–1400. The mud was sandy and sweet, with a hard gravelly bottom, 1401–12, 1416. "Saltings," which are used for repairing the banks, with the aid of planks and stones, have not caused a deposit of mud, 1295–8. Last winter he tried to regain an anchor which was lost in mid-stream near the sewer, but failed to recover it. Attributes its loss to the depth of the deposit at the bottom of the river in which the anchor buried itself, 1299–1306. The sweep line, when hauled in, was covered with deposit as thick in circumference as witness's arm, 1307–9.

Set of the Tide.—There is an under-current, both at the ebb and flood tides, but it is not so strong as at the surface. In the bays there are back waters or eddy tides under the lee of the points, but they do not interfere with the current of the tide, 1290–4. Sewage discharged at Crossness at high water on a spring tide would drift down to Gravesend. Has drifted as far in his boat without touching the shore. It would return on the flood to Erith. If discharged on the flood, it would go to Greenwich. If discharged four hours after high water, it would go as far as Purfleet and return to Woolwich, 1287–9. Has noticed it daily, because he has been towed up astern of steamships, 1284–6.

Injury to Fish.—Erith Reach was the principal and best fishing ground in the river up to 20 years ago, 1219–22. Has fished from Greenwich to Gravesend, and caught all kinds of fish. The largest quantity of fish ever caught was in Erith Bight, 1223–8. Within a week after the opening of the outfalls the fish were seen swimming on the top of the river, and the swell from the steamers drove them ashore, and they died. This has continued ever since, and no fish are to be caught now in the river above Gravesend. The men are driven down to the sea, 1229–34. Whitebait and eels were used as bait for hooks, which were laid on the bottom, but now the hooks and lines would become fouled with filth, 1235. Fourteen or fifteen boats used to fish at Erith, 1245. Shrimps can only be caught in the Lower Hope now. Two years ago they were to be caught at Gravesend. Eels were caught as high up as Woolwich, 1263–5. A month ago he tried fishing at Greenhithe, but caught nothing, and his lines are so stained that it will not come out, 1266–68, 1310–16. Never remembers such a thing happening before, 1317–9. Where there is a great accumulation of mud it is no use fishing for eels or flounders. The hooks and baits would be buried, 1320–3. Has caught more whitebait off Greenwich than any other place, but now has to go to Southend and Sheerness. Whitebait swim on the surface, or within a foot of it, 1324–8. The small amount of refuse coming from the factories has not affected the fish, 1417.

Mr. EDWARD SAVERY.

Examining Officer of Customs at Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been at Erith nine years, and is on the river every day. In hot weather the river is very bad; but the last few years, owing to the wet season and cool weather, it has not been so bad as in former years, 1421. The sewage can be seen distinctly in the river. The water is hardly ever clear now except sometimes just after low water, 1423. Has known the river for 40 years, and can remember drinking the

## Mr. EDWARD SAVERY—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

water at Erith and Blackwall. It was then very clear. Vessels going to sea used to take their supply of water from the river about half-an-hour before the flood, as it was then freshest, 1424–5. Thinks none would be so unwise as to drink it now, 1426. There is a great perturbation in the water now apparently from air bubbles. It was formerly like spring water, 1427–8. Amongst sailors there is a common idea that water is not fit to drink, or rather not good, after you have gone to sea, until it has undergone one fermentation, 1429. The water at Purfleet would not be drinkable at low tide if there was no sewage now, on account of its being brackish, 1432–7.

Offensive Odours.—The smell from the river can be noticed on shore, but at times on the river it is unbearable, and if it lasted, would incapacitate the men from doing their duty, 1421. It is worst in Half-way Reach, where the sewage is quite black, 1422. At low water on a hot day the smell is dreadful, 1442–3, especially from half way down Erith Reach to the top of Halfway Reach, 1465–9. Has noticed the smell from the factories in the atmosphere, but not from the river. They get the smell from the factories in the houses at Erith, but seldom the sewage odour. Can distinguish between the different smells, 1470–3, 1509–10A.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—From Erith, and a little below Erith, up to the outfall, there is a large accumulation of black sewage along the banks, and he has lifted some with the blade of his scull. It appeared to be pure black sewage. This deposit is not found in Long Reach or at Greenhithe, Grays, or Purfleet. Why, he cannot say, but it extends from the outfalls to Erith Reach, 1430–1, 1474–9, 1511. There are eddies in Erith Bight, and vessels swing up two hours after ebb-tide as if it were flood-tide. It is due to the silting up of the river, 1438. Small vessels which used to anchor close in under Erith Bight to wait for the tide now have to anchor at least 50 yards further out in the stream, and steamboats which used to go without difficulty over a certain course now stir up the mud. The deposits on the shore are now 15 feet high, 1438–40. The deposit is not due to the breaking down of the river banks. It smells too much, 1441. In consequence of the accumulation of sewage, which some people say is the banks of the river, the causeway has had to be lengthened twice, in all about 90 feet. The sewage lies in heaps and piles, and is decidedly increasing. "It is black and smelling," 1444–46. The principal place for the deposit is Erith Bight, 1461–62, 1474. The mooring buoys off Erith are not now in such deep water as when they were put down, and vessels ground now when before they would float, 1463. Has pushed a scull between five and six feet into the mud, 1464. Has observed the accumulations increasing daily for four or five years in Erith Bight, 1480–2. Several thousand tons have been removed by dredging, and the shoal known as Erith Rands has been removed. The channel is consequently much improved, but a vessel grounded there not long ago, 1483–6. The channel, being deepened, takes the stream more over to the north side and causes an eddy on the south side to a certain extent, which *might* have the effect of accumulating mud (not sewage), 1487–91. Is able to distinguish between sewage mud and river mud from seeing the delivery of genuine mud at the cement works, 1492–5, 1506–8. Part of the sewage of Erith is discharged into the river by an open sewer. A great part of the Erith sewage, however, goes into cesspools, and not into the sewer, 1496–1505. Is of opinion that if the present system of discharging sewage into the river is continued it will silt up the river, 1512. The mud used for making cement is of a light colour, but in all his experience of deposits he never saw any deposit which looks and smells like that which is seen at Erith. With a long enough probe you could pierce it to the bottom, which is estimated at 15 feet, 1516–19.

Set of the Tide.—The sewage discharged into the river at the outfalls would become so mixed with water that it would not be perceptible below Northfleet Hope or Southend, 1451–5.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has had applications from the officers on board ships for medicines to check diarrhœa, which it was presumed was caused by the state of the water, 1460.

## Mr. EDWARD SAVERY—*continued.*

Injury to Fish.—Fish used to be caught until about six years ago about Erith and Halfway Reach. The eel-scoots had to leave Erith *before* the opening of the outfalls, which he attributes to the state of the river. The sewage which used to be such an annoyance at Westminster now causes the same annoyance at Erith. The fish are poisoned by the sewage now as then, 1447–9. The eel-boats, as well as other fishing boats, stop now at Thames Haven, 1450, 1456–9. The discharges from the factories do not kill the fish, because it is well known that fish are abundant in the Tyne, where there are more factories than on the banks of the Thames, and therefore the conclusion to be drawn is that the sewage and not the chemical works kills the fish, 1512–15.

## Mr. JOSEPH HATHAWAY, East Greenwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been on the river for 50 years as a fisherman, and in the Thames Police, 1520–3. Prior to 1865 the water in the river was in a beautiful state, and could be drunk in any reach, 1530–2. Has drunk it himself, and has seen ships outward bound taking it in at Deptford, 1533. When the water was clear the fishermen's nets lasted twice as long as they now last. The water in its present state rots the nets, and it is impossible to clean them; they smell so bad also "that you can hardly bear them in the boats," 1561.

Offensive Odours.—As inspector in the Thames Police, his district extended from Blackwall to Deptford Creek; and has smelt the river in consequence, 1566–8. The smell from the river does not reach his house, but on the river has detected it as far up as Blackwall Reach, and even in Greenwich Reach when the spring tides are "running heavy." When on the river in the police galley, "especially in the summer time, there used to "be such a faint, nasty, stinking smell that you could "hardly bear it, and it turned you sick" when the sewage was being discharged, 1589–1600. If the police saw offensive matter in the river, they had to summon the people, 1601–2.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There is a large deposit of black stinking mud on the banks on both sides of the river. It extends on the south side from Crossness to Erith. The causeway is overflowing with five or six feet of this sewer stuff. It goes from the bank to low water. The causeway has been lengthened and raised three or four times, and will have to be raised again. At Jenningtree Point, where 20 or 30 barges used to get sand, they cannot get it now, 1553–60, 1574–6.

Injury to Fish.—The best part of the river for fishing is Erith Reach. There used to be 25 to 30 boats fishing there, but now no fish can be caught between Greenwich and Gravesend. They began to decrease in the upper reaches about 16 years ago, 1524–30. Flounders, eels, whitebait, and shrimps, used to be caught by tons off Greenwich, 1535. The highest point up the river where whitebait can be caught now is the Lower Hope, but none has been taken in Erith Reach or Halfway Reach for at least 14 years, 1536–7, 1569–73. In taking live fish to Billingsgate, they must be taken out of the wells after passing Gravesend, until the sewage water is passed. They will live better on deck than in the sewage water. It poisons the fish. They can be replaced in the well (on the flood tide) after passing Greenwich, 1538–48. The well communicates with the exterior water, 1549–52. Gave up fishing in 1851, when he joined the Thames Police. The water at that time did not foul the nets, 1563–5. The Dutch eel-scoots, which used to come up to Erith, now lie at Holy Haven, and the eels are packed in trunks and sent up to London. They do not go up to the Pool with the eels in the wells, 1579–80. Attended a meeting at the "Golden Anchor" to discuss the evidence to be given before the Commission, but was not asked to speak "against the sewage," 1581–8.

## Mr. JAMES WILLIAM FARTHING, East Greenwich.

Waterman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is a Greenwich waterman, and has been on the river 62 years, 1604–6. Before the outfalls were opened the water was very good,

## Mr. JAMES WILLIAM FARTHING—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

and ships used to take their supply of water for the voyage out of the river, principally at Greenwich, but also between Limehouse and Woolwich, 1607–12. They ceased to do this about 14 years ago on account of the impure state of the river, 1614–18, 1620. The water has been getting worse every day during the last eight or ten years, 1621–2, 1672.

Offensive Odours. — In summer time, when the weather is warm and calm, at high water the smell from the river at Greenwich is unbearable. "It stinks "awful." The discharge from the outfalls on the last of the ebb does not go down, but settles. When the flood tide runs up it carries the sewage with it and causes this bad smell, 1673–8.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—In hauling up an anchor, it is found always to be covered with a mixture of mud and greasy slime, which has an offensive odour, 1633–6. Along the south shore from the sewers to below Erith there is a deposit which, if stirred up with a scull, proves to be a mixture of mud and slime, 1636. There is a great deal less water in the river than there used to be down to Gravesend, 1637–8. [At this point a discussion took place between the chairman and the counsel as to formation of the mud banks in the reaches, which it is conceded exist, and reference was made by Mr. Bidder to the arbitration which took place between the Thames Conservators and the Metropolitan Board of Works as to whether these mud banks were caused by accumulations of sewage, and it was decided that they were not. Mr. Morice stated that he was going into the question of what the banks were caused by, and after some extracts from the report of the arbitrators had been read the examination of the witness was continued, 1639–50, 1653, 1658–60.] There has been a great increase in the banks of mud from Halfway Reach to Erith. It is not mud, but a nasty greasy soil, 1651–2, 1654–5, 1657. The banks used formerly to be made of "saltings," 1656. The deposit is in colour yellow and black, 1661–3. Twenty years ago there used to be 15 or 16 feet of water, while now there are not above 10 feet, 1667.

Injury to Fish.—The eel-boats used to lie off Erith before the outfalls were opened, and after that in two years they moved down to Gravesend, and then to Hole Haven, because the foul water killed the eels, though they are hard fish to kill. They will live longer out of water than they will in bad water, 1619–23.

## Mr. JAMES CLARKE.

### Bootmaker.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been a watchman at Price's oil works on the banks of the river, and can remember the river for more than 50 years, 1679–83. The river was pure before the outfalls were opened, 1684–5. Used to bathe in the river until he was twenty years of age, but it is not fit to bathe in now, 1688–90. Remembers the refuse from the factory running into a ditch which discharged itself into the Thames. The refuse now runs into pits, 1724–8. The factory is situated about 200 yards below Jenningtree Point on the south side, 1729. There used to be seaweed in the Thames just above Erith which was used largely for manure about 1855, but it has not been obtainable in large quantities the last 10 or 15 years; it is dwindling away, 1730–5.

Offensive Odours.—The river gives off an unpleasant odour, similar to decayed animal matters, which affected his health, 1698–9. It is worst during the hottest part of the summer, 1702. Has not noticed any unpleasant smells in connexion with Price's works unless it is from the smoke, as the fumes from the acids destroy any other smells. Has seen complaints in print on the subject, but attributes it perhaps to a desire to injure the firm. When the wind is in the east, it would carry the smell inland, 1715–19. The smells from the factory are quite distinct from the sewage smells, 1736.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The river has been filling up in different parts of the channel, both north and south, since the outfalls were opened, and if

## Mr. JAMES CLARKE—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

dredging had not been carried on, no ships of heavy draught would be able to come up, 1686–7. Thirty years ago there was hard dry sand from the lower ballast wharf at Erith to Jenningtree Point, but there is none now. It is "black slimy mud up to your middle," 1691–2.

Effect upon Health in the Neighbourhood of the Main Outfalls.—In 1867, when employed at Price's works, he fell from a barge into the water, and, when taken out, was much exhausted, and ill for several days from the effects of swallowing some of the water, which was in a very foul state, 1703–6, 1708–14. Has felt ill effects from the smell of the water when working alongside of the river on many occasions, 1698, 1707

## Mr. JOHN THORNE, Greenwich.

### Fisherman and Waterman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Was formerly a fisherman, but is now a waterman, 1738–41. The river was in a very good state before the outfalls were opened, and the water was always used for drinking purposes. The smacks took in their supply at Barking, 1742–4, 1795. Now the water is very bad, very black, and very stinking. It has been so more particularly since the outfalls were opened, 1745–7. It was good as far up as London Bridge, and even further, except in 1852 or 1853, when the river was in a bad state, but nothing like it is now. Never heard any complaints of the condition of the river in those days, 1783–8, 1794. Now, between Woolwich and Greenhithe, if the nets are put into the river, they get covered with slime, and so they never put them in it, 1776–1777. There used to be red worms in the mud, but now there are none. They are all killed, he supposes, 1801–8.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There is a great difference in the colour of the mud during the last few years. It is not mud, but more like slime, and very black. The Medway is clear, and not like the Thames at all now, 1778–82.

Injury to Fish.—Has left off fishing for nine years, but before the outfalls were opened Erith Rands was the best place in the river for fishing. There used to be 30 to 40 boats fishing there, but they have had to leave there and go down to Grays, Greenhithe, Gravesend, and the Lower Hope, about 15 years ago on account of the sewage, 1748–62. In taking fish to Billingsgate, they have to be taken out of the wells at Gravesend and placed in the boats to avoid the sewage water, which would kill them if left in the wells. They die at once if put into bad water, 1763–73. They can be put back into the wells off the Custom House at times if the water is good, 1766, 1774. The Dutch eel boats do not bring the fish up to London in the wells, but clear them out at Holy Haven, and are towed up to London as a rule, 1790–92. Comes up to Billingsgate once or twice a week, but his work now is to pilot small craft up the river, 1809–21.

## Mr. THOMAS PARKINSON.

### Trinity Pilot and Waterman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been on the river nearly all his life, and remembers when the water was good and the shores clean mud. What was sand is now yellow green muck, and there are only nine feet of water in Halfway Reach where formerly there were 15 or 16 feet, 1826–30, 1881. Colliers and coasting vessels used to "bring up" on the south shore, but there is no water for them now, 1831–32. As an apprentice always drank the Thames water, and outward-bound ships took their supply of water from the river. It is rank poison now, 1833–41.

Offensive Odours.—In heaving up a ship's anchor, the smell from the river is noticeable, and in towing up astern of a tug or on a steamer, the smell is bad enough to choke you. It is worse in hot weather than in cold, 1864–65, 1869. The worst places are Halfway Reach, Tripcock, Woolwich, and thereabouts, 1870–72. Also in Long Reach, 1880. No one can go up or down without smelling it, 1872.

## Mr. THOMAS PARKINSON—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—In getting up an anchor, there will be plenty of "muck" on it as well as on the chain, and it is necessary to place a man in a boat forward with a broom to wash both the chain and anchor as it comes in, otherwise the deck would be smothered with it. The smell from the deposit is very bad, 1847–55. It has been getting much worse of late years. There is less water all the way down; and it is due to the accumulation of mud or muck from above the outfalls down to Long Reach, 1856–59. Where the barges used to get sand at Jenningtree Point is covered with this filthy deposit, 1860–61. The deposit at Erith Causeway is soft muck of different colours, 1862–63. Long Reach, Erith Reach, and Halfway Reach have silted up, and the deposit on the sides at low water is a sort of brown colour. It extends as far as Gravesend, 1873–7. Vessels which used to ride in Halfway Reach on the south side cannot do so now, as there is only nine feet of water, where formerly it was fifteen feet deep. But there is more water on the north side, as the shelf at Dagenham Dock has been removed, 1881–7.

Set of the Tide. — Sewage, he believes, can be taken up to the Pool, as the flood would take it up farther than it goes on the ebb, 1843–6.

Injury to Fish.—Fishermen used to be seen on all parts of the river, and 30 years ago they used to catch whitebait off Greenwich and send it to London, but no fish would live there now 1866–68.

Bathing.—People used to bathe at Gravesend, but there are no bathing machines there now, nor have there been any for a long time, 1878–79.

## Mr. WILLIAM BRILL, Woolwich.

### Fisherman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Before the outfalls were opened, the river was in a very pure state, 1930–1. Twenty years ago was in the habit of drinking the river water between Erith and Greenhithe, but has not done it lately because it is not fit to drink, 1955–7, 1995–2005. The water when the sewage is discharged into it is of a very greasy nature, and has a different colour, a sort of green greasy nature to look at. It would very soon rot the nets if worked in the sewage water, 1964–9.

Offensive Odours.—Has noticed a very bad smell from the river at Erith, which can only be compared to the smell from a cesspool, but has never felt any ill effects from it, 1951–3. In going up and down the river has frequently to keep his handkerchief to his nose on account of the stench, 1954. In hot weather it is worst, 1981–3.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Prior to the discharge of sewage, the shore on the south side of the river was quite clean, and the fishermen could work their nets along the shore and catch large quantities of fish. Now the shore is all "slushy muck," smelling very strong, and nothing can live on it, 1938–42. There used formerly to be plenty of water in Church Hole, and now it is quite shallow with a "slushery" mud. It has been getting worse every year, and is increasing fast lately all along Erith, 1946–8. If the deposit is ever washed away it very soon appears again, 1949–50. The mud in the river is totally different to what it used to be. It was at one time hard pure mud on which you could walk, now it is slushy, and would come up to your middle if you got into it, 1977–80.

Set of the Tide.—The tide sweeps round Jenningtree Point and down Erith Reach, and settles in Erith Bight principally, 1943–5. The sewage at the farthest would not reach beyond the lower end of Gravesend Reach. Judges this because they have to remove the fish from the wells when they meet the sewage, 1958–9. Has seen lumps of sewage as well as in a liquid state floating in the river wherever the sewage goes. Has seen it above Crossness, 1970–2.

Injury to Fish.—Has been a fisherman nearly 50 years. The best fishing ground was from Greenhithe to Blackwall, but there have been no fish above Erith

## Mr. WILLIAM BRILL—*continued.*

Injury to Fish—*continued.*

since the opening of the outfalls. Now they have to go to Lower Hope, 10 miles below Gravesend, to get fish, 1929, 1932–4, 1984–7. Worms used for bait could once be found in the mud, but they have disappeared now, 1935–7, 1988–91. Fish cannot live in sewage water; they die at once, and on reaching the foul water the wells are emptied, and the fish placed in the boats, 1959–64. They cannot be put back into the wells until Greenwich or Limehouse are reached, 1972–3. Has not fished for a year, having lost his boat and gear, and has been unable to replace them, 1974–6.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Enjoys very good health, as he has not been affected by the smells from the river, 1953, 1903–4.

## Mr. GEORGE YOUNG, East Greenwich.

### Fisherman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—The state of the water is so bad that unless the nets (which required tanning once a month) are tanned weekly, they would rot, and the boats' bottoms have to be scrubbed every time they come up, when formerly it was only necessary every three weeks, 2034, 2062–5. All the way down on both sides of the river the sewage poisons the water, killing the fish and the worms, 2047–9. The bottom of the river used to be sandy, but it is not the case now, 2035–70. An inch line, let down to sweep for a lost anchor, when hauled in, was found to be coated to a thickness of three inches with all manner of filth, 2020, 2083–6.

Offensive Odours.—The deposits in the river and on the banks smell dreadfully, more like a closet, and if you put your hands into the water it is difficult to get them clean, 2023–4. The smell is noticeable at Erith and in the Reaches above, 2081.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The bottom of the river is nothing else but filth, and there is the same deposit on the south shore from Jenningtree Point, 2020–2. Has shoved a staff six or eight feet into the filth in the Bight, 2037. The Erith Causeway has been lengthened in consequence of the great increase of deposits during the last few years. Used to moor their boats to the Causeway but cannot do so now. No anchor would hold with any wind, because the bottom is all "slather,' 2038–46. In Halfway Reach the "banks" are clean because they are intended only to prevent the water from going into the marsh and are not reached by the mud, 2050–2, 2079. The saltings are astride the banks, 2077–8.

Injury to Fish.—Has fished for 40 years. Before the outfalls were opened used to catch fish up at Greenwich and down to Erith. The best fishing ground was Erith Rands, 2006–10. Two years after the sewage came into the river they were driven down by degrees to Gravesend and Lower Hope, and now they have to go to the Medway, 2011–16, 2019. No fish are caught higher up than Lower Hope, 2017. In Long Reach the fish have to be taken out of the wells on account of the sewage. It makes them like drunken men. They are put back again in the Upper Pool, 2027–30, 2081. Salt-water fish will live in *pure* fresh water, 2331–3. Fish will not live at Gravesend now, and their absence is the indication of sewage. They might be caught perhaps a mile and a half lower down, 2058–61. Tried to catch fish off Grays a short time ago, and the baits came in on the hooks untouched, but covered with filth, 2073–6, 2083–6.

Effect upon Health in the Neighbourhood of the Main Outfalls.—When about Erith cannot stand the smells. They make him sick and he is obliged to keep his handkerchief to his nose, and take brandy to remedy the sickness, 2054–7.

Set of the Tide.—The sewage is carried down as far as Gravesend with the ebb tide, and witness forms this opinion from watching the fish in the wells and the effect of the foul state of the water on them, 2025–9.

## Mr. THOMAS HARRY SIBLEY, Erith.

Foreman and Lighterman for Messrs. Pigou and Wilkes.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—His duties are to see craft loaded and unloaded in Magazine Creek, just below the outfall, 2087–9. The river there is in a filthy state, owing to the refuse that comes from the outfalls, which smells like dead bodies floating about, 2090–4. Has known the river twenty-four years, and before the outfalls were opened there was only mud, or rather sand, there, 2118–20. Has often noticed sewage on the water, and has seen grease taken out of the river, half a hundredweight at a time, and believes several people get their living by it. It is generally collected at high water when the wind is on the land. The discharge generally commences about high water, 2132–8. Has never noticed any discharge of refuse from the factories or gasworks, 2182–6.

Offensive Odours.—The river in hot weather is very offensive, emitting a rotten sort of smell, 2092–5. The deposits in Magazine Creek, which are entirely due to the discharge from the outfalls, smell very bad, 2115. Denies that the smell in the river is due to the different factories, as they discharge no refuse into the river, 2153–6. The gradual increase in the smell is not to be attributed to the yearly increase in the number of factories, as the smell from them goes on all the year round, and is totally different to the smell from the river, which is strongest in hot weather, and is due to sewage, 2157–75, 2179–81.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—In Magazine Creek there is a deposit of "slush" (which is nothing but sewage) increasing every day. When the outfalls were first opened, it was not necessary to cleanse the creek with a sluice more than once in three months, but for the last ten years it has had to be done every fortnight. If left for six months the "roadway" into the creek would be blocked by the accumulation, and the creek would not be navigable, 2096–2113. Church Hole has been filling up with sewage deposits, causing an eddy tide, and preventing large ships from anchoring there, as in former days. The accumulation has increased very greatly during the last few years, 2122–31. Believes the set of the tide is the same now as before the dredging took place at Coldharbour Point, 2190–1.

Effect upon Health in the Neighbourhood of the Main Outfalls. — The smell from the river in hot weather is so bad that he, and others, have had to leave their work for a time, they have felt "so queer," 2116–17.

## Mr. WILLIAM HENRY JOSEPH McKEE, Erith.

Lighterman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is foreman and lighterman to Messrs. Berry and Edwards, and works principally at Messrs. Curtis and Harvey's Magazine at Jenningtree Point. Has been on the river eighteen years, and with his present employers ten years, 2192–9, 2201–02. Ten years ago the river was in pretty much the same condition as it is now, 2200. At high water the river is all dark fluid, and floating masses come away from the sewers, owing to an eddy inshore. This happens every day, and the water is brown and thick at these times. Solid, as well as liquid, matter is seen floating about which gives off a very offensive sickening smell, and the barges are covered with slime, 2203–18, 2220.

Offensive Odours.—Offensive smells come from the factories in the localities, and can be smelt nearly every day. It depends on the direction of the wind what you smell; but these smells are totally different to the smell from the river, which is worst in hot weather. It is not so perceptible in the winter, 2221–49. Thinks he noticed the smell on about fifty and sixty days last summer, 2250–5.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The smell does not affect his health much, or his appetite, though when the smell is great, and the sewage is being discharged, it is unpleasant, 2256–7, 2260–1. The men employed on the barges complain a good deal of the smell, and the slime on the sides of the barges, but they have not been obliged to knock off work on account of it. They have pretty good health, 2258–9, 2211–12.

## Mr. JOHN GODFREY LEE, Erith.

Waterman to the Corinthian Yacht Club.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river about Erith seven years. It is very bad at the last quarter-ebb there. An eddy tide runs up for about an hour at half-ebb, and then runs down again, thus bringing the sewage down to all parts of the shore about Erith, 2262–9. The Club causeway is private property, and was built about three years ago, 2318–19. Yachts, which formerly lay off the old pier and other places, now lie off the Club House in Church Hole, owing to the filthy state of the river, 2318–26.

Offensive Odours.—A very bad stench rises from the sewage deposits at Erith, which, on a warm morning, is so powerful that it takes away your appetite, 2270–71.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—In calm still weather, actual sewage is deposited in Erith Bight by the tide in large quantities. It has greatly increased during the last seven years. The direction of the wind does not affect the deposit much, 2273–8. The Club Causeway runs down to the river about 350 feet. In hot weather, at low tide, it is not fit to walk on, unless scrubbed down every day, because it is covered with slime and dung. This deposit is left there all the year round as a rule, but the stench and smell are enough to choke you. A boat's bottom will get coated with it in one tide, and they have to be cleaned and re-dressed four or five times every summer to keep them in proper order, 2281–91. A strong north-east wind will sometimes cause a decrease in the deposit to the extent of four or five inches, but, on the other hand, in still weather, it will accumulate to the same amount in a week. At high water, in a gale, the surface of the water is as bad as the bottom, 2292–3. The mud on the shore is like grease, and "slicker." It is difficult to remove it from your clothes or boats, 2294–5. The "mud" does not accumulate very much at the Club Causeway, but it is "slickery" stuff, 2313–17.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has often had headaches and sickness from the smells in the summer time, but it does not affect him in the cold weather. His wife and daughter have suffered from the smell, and are obliged to go away during the hot weather. His son's health is not affected at all, 2279–80, 2298–305.

## Mr. WILLIAM HOSKINS, Erith.

Lighterman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river for 40 years, and the water was clear and fresh before the outfalls were opened, and fish were caught between Greenwich and Erith. For the last 14 years that has not been the case, 2327–36. Is aware that four or five drains or sewers, which come from butcher's premises and others discharge into the river at Erith, 2394–6, 2408*a*–9, 2414–6. Has noticed the alteration in the colour of the water at half tide when going up and over the river. It is like black filth, 2345–7, and in rowing a boat through it, it is like a lot of mud, 2350.

Offensive Odours.—There is a very bad stench from the river, frequently about half ebb tide, which he has noticed in Halfway Reach, 2349–50. At Erith the deposit caused by the sewage smells very bad. It is noticeable on the shore from the sewage in the water, 2397–400. It is perceptible at all times of the year, but is worse in summer than in winter, 2410–13. There are plenty of other smells up and down the river from factories, but they are quite different to the sewage smell, and are easily to be distinguished. The sewage smells far worse than the factories, 2401–8.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Along the Halfway Reach and Erith Bight there is a great deal of filth on the shore. It is not mud, but it is grease, without much smell, and has increased considerably during the past few years. It is principally in the Bight between Church Hole and Erith Causeway, and is four or five inches deep. Remembers when he could get into his boat, at low water, with three steps, but now cannot get within five boats lengths at spring tide, though the causeway has been lengthened 60 feet, 2363–72. In hauling ropes into his boat they are coated with grease, 2390–3.

### Mr. WILLIAM HOSKINS—*continued.*

Injury to Fish.—Up to nine years ago there were large quantities of mud worms which were used for bait between Erith and Woolwich, but there are none left now. Fishing boats used to come up to Greenwich, but now they have to go below Gravesend to fish, 2331–44, 2375–8.

Set of the Tide.—Three years ago he made an experiment with bottles to test the distance the sewage travels from the outfalls. Bottles put in at Crossness on a strong spring ebb and westerly wind drifted down to the "Lobster" at Gravesend, 2352–9. That would be a distance of 13 or 14 miles, and the time occupied was about six hours (the whole ebb), 2380–9.

### Mr. CHARLES FAULKNER, West Street, Erith.

Contractor.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has lived at Erith 63 years, and his work has been chiefly connected with the mud of the river, 2429–34. Twenty years ago it had a pure salty smell, but it began to alter 16 years ago, and smelt badly, driving the fish away, 2437–9. In summer time, after working in the mud, it requires four or five washings to remove the smell from your hands, 2441.

Offensive Odours.—His work is to lay the berths level for the barges at Price and Harvey's oil works, and the smell from the accumulation of mud on the berths is very bad. It is worst in the summer time, 2462–4, 2510–12. Has smelt the water from the banks of the river, 2515–20.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There is an accumulation of black mud on shore at Erith to a depth of one foot and a half, which has increased for the last 20 years, and smells like night soil, 2442–7. There is not so much water between the club-house and the old pier by eight to ten feet, 2447–51. This black stuff settles in the bight, and the water is slack. There is also an eddy-tide, 2452–7. Has considerable difficulty in clearing away the mud from the berths, and has seen the sewage intact deposited on the berths. Sometimes it is necessary to clear the deposits on the berths, two or three times a month; and he does this when the tide is running down, so that it sweeps the stuff away, 2465–7. There are two reservoirs by the wharves which fill with the tide, and when the tide falls the "flap" shuts, and the water remains. A sluice gate is then opened to let the water out, which washes away the accumulation of mud. They were made 18 years ago, 2479–94. The old reservoirs, which were made when he was a boy, have been done away with. Their object was not so much to clear away mud, as to keep the beds clean, 2494–2508, 2521–3.

Injury to Fish.—The opening of the outfalls caused bad smells in the river which has driven the fish away. When a boy, remembers trawling off Erith and catching plenty of fish, 2433–40.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Enjoys pretty good health, and, with the exception of gout, there has been no difference during the last twenty years, and the time preceding it, 2469–74.

### Mr. WILLIAM HARLING, Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has worked at the ballast wharves for twenty years, and when he first went there the water was clear, and fish were caught at that time, 2524–7.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—During the last fourteen years there has been an accumulation of black greasy filth along the shore, which has got worse lately. It sticks to your finger nails if you try to wash it off, and stinks, 2537–41. Large lumps of human manure float down the river and remain on the sides of the dock, 2542–3. Has to keep the berths clear where the ships come to take in ballast, 2544–6. The filth settles on the steps as the tide goes down, and also on the banks, 2552–6. The docks where the ships lay alongside the wharves have to be cleaned out by means of reservoirs every tide, 2557–60. The reservoirs have to be cleaned out every other week to remove the mud and "slurry," 2574–8.

### Mr. WILLIAM HARLING—*continued.*

Injury to Fish.—Twenty years ago Erith was a good fishing place, and sometimes a hundred baskets of fish being caught on a Monday morning. The boats stopped coming up fourteen years ago, 2547–56, 2571–3.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Every time he goes into the dock to clear out the "mud" he has to go to a doctor. He feels sick and "faintified" and short-breathed after it. This has been going on for the last three or four years, 2547–50. Never felt it before, 2551. The dock is a sort of mud berth alongside a staging, which is a ballast wharf, 2561–9. One of his mates is similarly affected. Previously enjoyed very good health. The doctor attributes the illness to working in the dock, 2579–96.

### Mr. HENRY CLARKE, Erith.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Has worked at the ballast wharves in the employment of Mr. Parish all his life, 2598–2601. Has to work in the mud occasionally, on the top of which a nasty black filth, resembling "stuff from the human body," settles, 2605, 2609. It has increased in quantity as well as in kind of late years, 2620–21. The reservoirs have to be cleaned out once in every fortnight, at spring tides now, as against two or three times a year when they were first made, 2622–6.

Offensive Odours.—The "mud" has a nasty smell rising from it, and there is also a bad smell from the adjoining wharf, where dung is brought down in barges and carted away. Has never worked there, 2609–10, 2627–35.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has felt ill effects from working in the mud, "a nasty faint sickness," more now than formerly. Working on it before breakfast takes away his appetite completely, 2601–8, 2612. Has had to go to the doctor for medicine about four times, but has never been laid up, 2610–18, 2637–42.

### Mr. WILLIAM GATWARD

Constable.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been stationed at Barking Creek about twelve years, about seven hundred yards from the northern outfall, 2643–5. The river in that vicinity is very low, and smells very bad indeed. There is also a quantity of refuse, such as fat, and bullocks' lights, left on the shore, which smells, and in hot weather is unendurable, 2646–7. From his station can see the sewage discharged from the outfall and run into the river. Its progress is marked by the colour on the water, 2652–58, 2814–15. Has seen large lumps of fat floating amongst the sewage on the river, and seven men get a good living by skimming the river and melting the fat down. It is known as "Thames mud butter," and is used for lubricating purposes. Describes the process of collecting and melting down, 2661–3. The lights he has noticed in the sewage about 300 to 400 yards from the outfalls almost every tide, but more particularly after a heavy rain, 2664–7, 2759–61. Believes the sewage of Barking is discharged into the Creek, 2760 to 2762. Is not aware of any refuse having discharged from the paper mills in the Creek or from the Barking Gasworks, 2763–6. Has had to row with a strong rippling discharge coming from them, 2767–8.

Offensive Odours.—There is "a very foul, nasty, sickly smell" from the mud left on the shore, 2661–2. Has also smelt it on other parts of the river, in some places it is very bad, you cannot stand it and is glad to run the first chance to get away from the smell, 2662–3. Has traced the smell as far as Greenwich when rowing for pleasure, 2763–4. The smells from some of the factories are very offensive, but is quite different from the river smell, 2764, 2769. Has heard the people living at the creek complain of the smell, 2765–67. At the mouth of the creek, by the railway, which runs down to low-water mark, there is always a smell from the river, 2768–74.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The mud or deposit left by the tide is almost black, and is greasy stuff, 2649–51, 2677–81. And large quantities of

MR. WILLIAM GATWARD—*continued.*

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

it remain on the causeway, 2659–64. On the foreshore below Barking the top of the mud is a greenish colour, 2673–5, 2737–9. The bodies of those drowned by the "Princess Alice" collision, when recovered, were in a most beastly state, their clothes being covered with slime and filth, which gave off an intolerable smell. Has never seen bodies in such a state anywhere but in the Thames, 2665–72, 2762–79, 2801–12.

INJURY TO FISH.—Has seen plenty of fish at this time of year after heavy rains come down, and directly they reach the water, which is contaminated by sewage, they die. Only a week ago one hundredweight of eels were picked up dead on the stones just outside Barking Creek, extending to half a mile below the outfalls. Has never seen live fish there. They become stupefied and can be picked up, 2682–6. It is a common thing to get eels in the neighbourhood of the outfalls at this time of the year, 2781–9.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—The smell arising from the mud and sewage in hot weather has often made him feel quite sick, 2647–8.

DISCHARGE OF SEWAGE FROM THE MAIN OUTFALLS AT IMPROPER TIMES.—Has seen the sewage come out from the outfall before high water, and also running up after low water, when the flood tide is flowing, on several occasions, 2653–7. Has noticed it this year, on the 25th August, running up on the flood towards Beckton. It is a different colour to the water, 2704–25. Can see it from his station on the wall, 2818–20.

## MR. GEORGE ROBERTS.

Inspector of the Thames Police.

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Has known the river between 30 and 40 years, and has been stationed off Erith for four and a half years. When the outfalls were opened he was at Blackwall, and has been quartered at different parts of the river as constable since 1860, as far up as Putney, 2821–24, 2826–34. Prior to that, was for 18 months in the Customs, and, in fact, has been on the Thames from his boyhood, 2835–41. Before the opening of the outfalls the water was in a very good condition, but it has been very bad since, such bad smells emanating from it, 2825, 2842–43. When in the Customs service, at low water, they used always to "dip" for their water to use in the boat, but they cannot do so now, it is so dirty and smells, and it is unfit for washing or drinking purposes, 2873–9. Has taken it out at Erith, but seldom below, as it becomes brackish there. It was quite suitable for washing and cooking, but not for drinking, at Erith. As a rule, Woolwich used to be the general place for "dipping" for drinking water, but has heard of smacks taking in their supplies of water at Barking Creek, 2880–6. In the bays and slack water there is frequently lots of fat and slaughter house refuse floating about, 2910. His "beat" is from Dartford Creek to Beckton, and is on the river at all hours, morning, noon, or night. The police vessel is moored off Erith Pier, 2953–64. When rain and fresh water come into the river, when the water has been very bad, it is sweetened a little, 2996. Can always tell when the "freshets" are down by the colour of the water, 2998–99.

OFFENSIVE ODOURS.—Has noticed bad smells coming from the river in hot weather, when the water is still most particularly, and also in close foggy weather, 2844. A steamboat stirs up the water, and makes it smell, 2867. By direction of his superintendent, he took notes of the state of the river from the 1st to the 4th August 1880, and noticed bad smells coming from the river. His report can no doubt be produced from the Commissioners of Police, 2929–52. The smells are like "rotten soap suds," a nasty filthy smell, and are most prevalent in Barking Creek and Halfway Reach. They are from the river, and has never noticed the smell on the land, 2965–70. Smells it when he is afloat, 2848.

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—The bodies recovered from the river after the "Princess Alice" disaster were terribly swelled, and in a decomposed state after being a very short time in the water, only two or three days, not more. Is unable to say whether there was

MR. GEORGE ROBERTS—*continued.*

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

any mud or deposit on the clothes, as he did not notice their condition, 2849–56. The mud on the foreshore above Erith looks terribly black and dirty, and smells badly at times when there is a wash on the shore stirring it up. It extends from Dartford Creek up past Erith as far as the Northern Outfall, 2857–63. For the last three months the mud appears to have been drawn off the river shore, as it does not lie so thickly on the shore as it did, 2863–66. Has "seen quantities of round "balls and the likes of that" "lying about on the "stones on the shore—greasy stuff, all up and down "on either sides of the river banks," 2908. The diminution in the deposits of mud has been considerable lately, and it appears to be accumulating towards the bed of the river. When rowing at low water, the oars stir up the mud 20 or 30 yards from low-water mark, 2972–3, 2986–8, 2994–5. The mud at Erith is of a bluish brown colour, and is darker at the mouth of Barking Creek. There is very little difference in it on both shores, and it is quite different to the mud at Greenhithe or Gravesend, 2974–85. The dredging machines at work in Long Reach bring up ballast and gravel principally, 2989–90.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—Has never been laid up, but has felt very sick from the smell when rowing about, especially when under the sterns of steamers, and also when the water is very still. Lives about a mile inland, 2845–7. One of the men under him was returned sick this year, and obtained leave of absence, as he was suffering from diarrhœa, which the doctor said was "probably caused by the bad smell from the river," 2912–19. Has four men under him, 2920. Cannot tell without his books how often the men have been off duty from sickness. They are, like himself, pretty strong, and not very sickly, 2991–3.

DISCHARGE OF SEWAGE FROM THE MAIN OUTFALLS AT IMPROPER TIMES.—On the 1st August 1880 noticed the discharge of sewage commence at Crossness at 9.30 a.m., *go up the river* with the flood. It was high water at London Bridge at 9.53 a.m., or half an hour's difference between the outfall and London Bridge. The sewage was flowing up at Barking at 10 a.m. the same day, 2887–91. On the 2nd received a report from one of his men that the sewage was *flowing up from the southern outfall*, and saw it himself do so from Barking. The same thing happened on the 3rd August, and on the 4th the discharge began about the time of high water at London Bridge. These observations were made by direction of his superior officer, 2892–2900. Has noticed it come out on the flood on other occasions, but not recently, 2901–2. Has seen the sewage a long way up the river above the outfalls. At Woolwich has seen the water quite black, and on his rounds has traced it up the tideway from Erith to Woolwich, 2903–6. When the water comes to its highest point adjoining the bank, it continues to flow from a quarter of an hour to half an hour, and the sewage discharged at high water would go up the river, 2921–5.

## MR. EDWARD ARUNDEL CARTTAR. Greenwich.

Coroner for the County of Kent.

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Succeeded his father as Coroner two and a half years ago. His district extends from Rotherhithe to Gravesend, mid-stream, and to the north side of mid-stream in the parish of Woolwich, 3000–6. Has held over eight hundred inquests, out of which 156 have been on bodies taken out of water, and 98 of these were drowned in the Thames, 3008–10. In 1881 held 32 inquests on bodies recovered from the Thames. The inquests are held in the parish in which the body is recovered, 3011–12. There is a marked contrast between those bodies taken out of the Thames and those taken from other waters. The bodies of the former are very much disfigured and discoloured, by the gas, he presumes. They turn various colours, and decomposition is very rapid in the summer, particularly in those cases which are found below Charlton. Two or three days are sufficient, 3013–14. Very often the bodies are covered with a deposit of mud and filth, and there are complaints about it. The matter has a very offensive smell, 3015–19. Bodies recovered from the Surrey Canal are comparatively clean, with but very little mud on them. From

## Mr. EDWARD ARUNDEL CARTTAR—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

the Albert Dock there is a slight deposit of mud on the bodies, but has not noticed any offensive odour or smell arising from it, 3020–5. From Charlton to Erith the bodies are in the worst condition, 3026–9. A man was drowned on the 16th July off Tripcock Point, and his body, when recovered five days after, was in a very bad state, disfigured and swollen, and covered with filth and slime. It was strongly commented on by the Jury, though they are used to bad cases, 3034–42. Has known the river about twenty-six years, and it has greatly improved of recent years from Greenwich and above; but below Greenwich it has become much worse, 3030–3. Any report in the local paper representing that he alone, and not the jury, made remarks on the state of the river after the inquest in July, is incorrect. A witness, Mr. A. Collins, has often made complaints as to the state of the river, 3044–49, 3068–78. Taking into consideration the difference of time in recovering bodies from the river, and those drowned in ponds, &c., there is a marked contrast between the condition of the bodies, 3051–6. So far as his observation goes, the state of the river below Greenwich is worse now since the outfalls were opened than it was before, 3057–67, 3080–2.

## Mr. GEORGE MASTIN.

Thames Police, Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been on the police boat at Erith three and a half years, and on the river about twenty-five or twenty-six years, 3083–6. Before the outfalls were opened the river between Crossness and Gravesend was much purer, and there was not the foulness in the water that there is now, nor did it smell so bad. Is on the river daily, 3087–91. The river water is used to wash the decks down with, but it cannot be used for any other purpose on account of its foul state. At times they have to skim the grease and slime from the surface of the water to get at the water underneath. Attributes this to sewage or the contents of sewers, 3100–3105. Dead bodies when taken out of the Thames are generally in a very decomposed state, and a recent case, after four days' immersion only, was very decomposed, 3106–11. Some of the bodies which were recovered from the river a few hours after the "Princess Alice" disaster had a reddish appearance and were discoloured, and froth was coming from their mouths, 3120–9. Has been in the Thames police about fourteen years, and stationed at various parts of the river between London Bridge and Gravesend, and prior to that he "served his time" on the river steamboats running between London Bridge and Sheerness, 3130–44. Has not seen any discharge from a drain or sewer at Beckton, nor any refuse flowing into the river from the gasworks there, 3146–64, 3183–4. There is a great difference between the state of the river now and what it used to be, 3185–6. The distance from Beckton pier to the northern outfall is from 300 to 400 yards, 3187. As a rule the discharge from the outfalls begins about high-water time, but has seen it come out a little before high-water and go up with the flood. In rowing down, has met the sewage coming up just below Halfway House. It is very black; has a most offensive smell, 3112–17.

Offensive Odours.—The smell from the mud on the foreshore between Erith and Beckton is very offensive, 3098.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—The mud on the banks has "a yellowish slimy look about it," and is not a sandy soil, as it used to be in former years, 3093.

Injury to Fish.—Remembers as a boy seeing the Dutch eel-scoots lying off Erith, but it is from seventeen to nineteen years since they discontinued coming there, 3118–19.

Effect upon Health in the Neighbourhood of the Main Outfalls.—At times has been obliged to leave the boat in hot weather on account of the smell from the water. Twice it has caused him to vomit, 3099. Once, when cleaning out the boat at Erith Pier, he had to go ashore and get some refreshment at a public-house as he felt so sick and faint, and did not go on duty again that day, 3165–82, 3188.

## Sergeant CHARLES GILHAM, Woolwich.

R Division of the Metropolitan Police.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been in the police force for ten years, and was coroner's officer for five years; before that he was in the navy, 3193–5, 3240–1. During the last ten years the state of the river has been very bad indeed, thick and dirty, with a very bad smell in hot weather, especially when the penstock is opened at North Woolwich, 3196–8. The "Princess Alice" bodies, which were recovered within twenty-four hours of the accident, were covered with slime and mud, large black blisters came on the skin, and they smelt very bad indeed. Those recovered later were much worse, 3199–3205. The clothing, which was saturated with sewage and slime, had to be boiled and disinfected in order that it might be identified, as the bodies were in most cases unrecognizable. Without this process the clothing, from its filthy state and bad smell, would not have been in a fit condition to show for identification, 3206–20. The blisters were full of black liquid and are of immense size. Bodies recovered in other waters do not decompose so rapidly, and turn green, not black, at first. If a body is taken out near Gallions Reach, or off Beckton, it will turn black and blister in seven or eight hours after being washed, 3221–33, 3261–5. Off Charlton they are not in so bad a state, 3236–49. Believes some of the refuse from the Beckton gasworks is discharged into the river, 3234–5. When the penstocks at North Woolwich are opened the water is discoloured for a considerable distance, which in warm weather smells very badly. The sewage from North Woolwich and part of East Ham is emptied into the river at this point, 3250–60.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The causeway at Woolwich has to be washed down as the tide recedes. It is very slimy and slippery, and covered with filth, generally black mud, which, in hot weather particularly, is very offensive, 3222–4.

## Captain GEORGE BENJAMIN LYNCH.

Principal Dockmaster of the Albert Docks.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river for forty years, and it used sometimes to be bad and sometimes pretty good. Steamers used to "dip" for water off the Custom House. In summer it was a little bad, but at other times it was very clear, 3267–9. Since the outfalls were made the water has been thicker, and the accumulation on the banks is blacker between the Victoria entrance and the Gallions entrance. It smells very much in hot weather, but not much in the cold season, 3270–4. The water is now quite unfit for use on account of its dirty condition as well as for the oily appearance of the surface at times, 3279–84. Has frequently noticed solid matter floating in the water, "filth" from the closets and that sort of thing," and has seen the sewage passing up the river, showing black streaky marks in the tideway, about half flood-tide, 3285–90. It is in fact a discolouration of the water, and is most noticeable in hot weather, 3332–4. Has heard of the "overflow water discharge," but not of any sewage discharge from the penstock at North Woolwich, 3335–8. Knows of no arrangement for getting rid of the refuse from the gasworks at Beckton, nor has he ever seen a sewer there, 3339–41.

Offensive Odours.—Smells are given off from the factories in the neighbourhood, but there is difference between the smell from the works and the sewage, which he is able to distinguish, 3299–3303.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There has been a considerable accumulation of mud in the basins of the docks during the last two years (since the docks were opened), and on the flood tide black water can be seen coming through the piles of the pier heads, 3275–7. The mud is blacker than it used to be, and smells very much, 3297–8. Has compared the mud with that at the Victoria Dock entrance, which is higher up the river, 3310–14. The two entrances are from two-and-a-half to three miles apart, 3315. The Albert dock entrance is three-quarters of a mile, and the Victoria entrance is about three miles, from the northern outfall, and the mud accumulates in both basins faster than it used, 3316–18. There is an eddy on the ebb-tide at the Albert entrance, but the two pier

## Captain GEORGE BENJAMIN LYNCH—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

heads which were erected, and run out into the river, for the purpose of docking ships, do not keep the mud out, 3319–22, 3342–4. There was always a deposit of mud in the Victoria Docks since they were opened in 1855, and it has had to be dredged up and sent away in barges, 3323–6. For a long time has had to dredge the basin out every three months, 3348. Has been connected with the Victoria Docks since they were opened, 3345 Dredging in the Albert Docks basin began last month, and it is quite a new dock, 3346–7.

Injury to Fish.—Has frequently seen dead fish on the banks of the river, more particularly in the summer time. They are to be seen wherever there are eddy tides, at the time the flood is running up, 3291–5. There used to be a great many fish in the Victoria Docks, and jack were caught there, but now there are none, and he has not seen any people fishing in the Docks for five or six years, 3327–31.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has known the men to complain of the smell of the water in the docks sometimes, 3278, and has seen them sick from it, but has not felt much ill effect from it himself, as it affects some people more than others, 3304–6.

## Mr. JAMES HENRY SHOWELL; Greenwich.

Inspector of the Watermen's Company.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—His duty is to board barges and craft on the river to see that the Act of Parliament is carried out, and has been on the river 24 years, 3350–55. Is 38 years old, 3400. There is a very great difference in the water of the Thames since the outfalls were opened. It is in a filthy state; there is a great amount of sewage in it, and it both smells and is discoloured. It was worst in the summers of 1880 and 1881, 3356–61. Has noticed the sewage in the river, specially by the thickness of the water, by the mud, and by the dreadful stink there is attached to it, 3362–63. The smell is worst in Woolwich Reach on the north shore, just as the tide is making. Has frequently seen sewage matter and other things come out of the sewers and floating in the river, 3384–5. In Sea Reach the water is very clear, especially on the flood tide; but it gets thicker as you go higher up, until you arrive at Limehouse Reach, when the water becomes clearer. The change is noticed first at Lower Hope, coming into Gravesend Reach, 3394–6. The Penstock at North Woolwich is about 600 yards above the ferry pier, but has never seen sewage discharged from it, because the sewer is under water at low tide. Has heard no complaints about it, 3424–8. Has never seen any discharge of sewage coming from the Beckton Gasworks, but he has smelt the gas liquor as the barges were being loaded with it, 3429–33. Believes there is a discharge of sewage into the river at Gravesend, but does not think it would account for the discolouration of the river there, as the sewer was there when the fishing boats lay there, and it never affected the eels, 3457–8.

Offensive Odours.—The most distinct and offensive smell from the river is on the north shore at North Woolwich, close to the pier, and just at the time of the young flood, 3421–3. The smell from the mud has greatly increased since the outfalls were opened, 3399.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Between Erith and Tripcock Point the mud on the south shore used to be of a whiter colour; now it is black, and stinks very much, 3364–5. Has frequently noticed a settlement of sewage along the shores in the different bights, which has increased in recent years, 3397–8.

Injury to Fish.—Used to work for the Dutch eel-boats off Gravesend 24 years ago, and bring the fish up to market at night, but has not done so for the last 10 or 11 years, 3366–71. The boats now lie at Hole Haven, in consequence of the advice given to them by the watermen, as the water is so bad, 3372–80. Does not recollect the boats stopping at Erith. His first voyage was made after the sewers were let into the river, and it was from Gravesend to Hole Haven. It was against the watermen's interest, pecuniarily, to recommend the removal of the boats lower down the river, 3401–14. Eels

## Mr. JAMES HENRY SHOWELL—*continued.*

Injury to Fish—*continued.*

can live in the pool. They are carried up in the wells, 3415–20. In winter there is plenty of fresh water in the river, which facilitates the transit of the fish up the river. In the summer they would not live if taken through the sewage water, and are brought up in boxes. If towed up in the winter, they are taken through the sewage so fast that it cannot touch them. The boats bring up about 12 tons each. The fish are better at low water than on the flood at Billingsgate, 3434–52.

Effect upon Health in the Neighbourhood of the Main Outfalls—In 1881 the smell from the river made him very sick, and he had to go ashore, and leave his boat. Has never actually been unable to do his duties, but has "felt very queer" nevertheless, 3386–88.

Set of the Tide.—From his experience of drifting in a boat, the sewage would drift on an ebb-tide to the lower end of Gravesend Reach, 3389–93. Has seen the water thick with dark matter down there, 3453–5.

## Mr. JAMES WILLIAM ROZIER.

Chief Inspector of the Watermen's Company.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been in the Company's service 18 years, and knows the river from Woolwich to Gravesend well, 3459–64. Since the outfalls were opened the water has become a different colour, and stinks, 3465–71. The bodies of people drowned in the Thames when taken out are black, and the clothes are covered with slime, 3472–5.

Offensive Odours.—In 1860 he used to take the fish refuse from Billingsgate to Dagenham to make manure with, and there was no smell from the river then. The only smell was from the fish. Now, when a steamboat goes down the river at low water, the mud is stirred up and smells, 3479–89.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The mud on the foreshore down the river is quite different from what it used to be, and is black as ink, with a very offensive smell in summer time at low water, 3476–8.

## Captain JAMES HUSSEY.

Principal Dockmaster of the East and West India Docks.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been at the docks for 32 years, and lives close to the Blackwall entrance to the West India Dock, 3501–2, 3548–50. At times, when there has been an accident to the Barking outfall, the sewage is pumped at Bromley into the River Lea, and it flows "in one solid mass" into the East India Docks, 3532–34, 3551–60. The Lea comes into the river just below the Blackwall entrance, 3560. The sewage in the water is very thick, but has not seen any solid lumps in it, 3601–3.

Offensive Odours.—On a still night, when the mud settles on the banks, the stench from it in summer time is something awful. There are no factories near his house on the land, 3509–10.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There has been an enormous increase in the accumulation of mud at the entrance to the docks and in the docks the last few years. At first when the outfalls were opened the deposit was less, but it soon increased, and has since been steadily working its way up, 3503–7. In 1879, 69,000 tons of mud raised cleared the whole of the docks and basins, which cover an area of 120 acres. This year 90,000 tons of mud have been raised, and yet there is left an accumulation of 70,000 tons. Has been obliged to employ a contractor to clear one basin, as the mud has overpowered him. It has a large percentage of sewage mixed with it, 3508. Attributes the increase partly to the sewage having come up from the outfall, and partly to the exceptionally heavy tides, which have brought down a lot of land water and mud, 3566–73. Can detect the sewage in the mud by its greasy slimy state, its bad smell, and by the dark colour to which it turns. Formerly the mud was sand colour, but now it is black, 3523, 3586–91, 3605–6. The mud when raised from the docks is taken to the Company's station adjoining the Crossness outfall, where 12 men are stationed to remove it from the barges, 3593–9.

### Captain JAMES HUSSEY—*continued.*

Set of the Tide.—The sewage took nearly two years and a half to reach the docks from the outfall, but it is working up gradually, and it now goes up as far as Limehouse. He tested the mud and found it to be mixed with sewage. There is a deposit of sewage at the back of his house and in the locks, which is brought there by the tide a distance of eight miles from the outfall, 3514, 3521–2, 3524–7. Sewage is discharged about the quarter ebb from the outfall at Crossness, 3515–20. The flood tide is stronger than the ebb, though the ebb runs an hour longer than the flood, and consequently sewage is carried up by the flood to a point above where it is discharged. He believes that in 18 months' time from now the sewage will drift up to Westminster, 3528–30. The sewage works its way up the river at the rate of about three-quarters of a mile a year. This statement is derived from observation of the time the sewage has taken to work from the East India Docks at Blackwall in 1879 up to the Limehouse entrance to the South Dock in 1882, 3538–47, 3574–85.

Effect upon Health in the Neighbourhood of the Main Outfalls.—His family and his grandchildren have suffered from the smells, and were taken ill while staying in his house, 3511–13. Has heard that one of his men was ill from the foul state of the mud, 3537, 3592.

### Mr. GEORGE FREDERICK FULLER, Granville Park, Blackheath.

Member of the Firm of Messrs. G. and A. Fuller, Government Dredging Contractors.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—His premises have a frontage of 1,000 feet at North Woolwich, and the river there is in a filthy state owing to an accumulation since 1879 of 18 inches of "mucky, filthy, browny-red stuff," which smells awfully in the summer, 3656–8. The Thames water was always used for crane boilers, but they are now unable to use it on account of its filthy state. It causes the boilers to prime and adheres to the tubes, and so burns them out. Now they are obliged to obtain their supply from the water company, which is an additional and great expense, 3663–7. Has had a good many barges sunk, and when they have been raised they have a bad sediment of mud and sewage on them, which collects at the rate of half an inch a day. This is not found on barges sunk below Gravesend, 3670–3. Experiences some difficulty in getting men to work in emptying the barges. They always require a great deal of refreshment on account of the filth and the smell. The difficulty is greater when the dredgers have been working above Gravesend than when working below, 3674–7. River steamers use Thames water for their boilers, but they get clear water and condense it. Without this precaution their boilers would very soon be worn out, 3699–3702. The river water was sometimes very bad and black in summer before the outfalls were opened, 3682.

Offensive Odours.—The mud brought up by the dredgers has a very unpleasant smell, 3653, and the mud at North Woolwich smells horribly in summer time, 3658. Before the outfalls were opened the river smelt very bad sometimes, but there was no smell from the mud, 3680–2.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—For the last 20 to 30 years has been in the habit of dredging the Thames from Woolwich to Gravesend for ballast and sand. Used to get clear building sand and ballast at the different points down the river, 3609–12. For 12 months after the outfalls were opened he used to dredge at Tripcock and Jenningtree Points, but had to leave them and go further down to Coldharbour Point, where he worked for three or four years. They were driven away by the filth in the sand, and by degrees they have got down to below Gravesend, 3613–33. When a lot of water comes down from the upper river the mud is partly cleared away, and a few freights of sand can be got at the different points up the river, 3628, 3631. Was able to work at Crayfordness for 10 years, but it is very dirty now. The customers complain of the filth in the sand, and will not accept it unless clean, 3633–40. For the last four years has got sand between "Fiddler's Point" (Stoneness) and Coalhouse below Gravesend, 3642–6. The sewage is mixed with the sand, and the men have

### Mr. GEORGE FREDERICK FULLER—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

to wash it when it is brought up by the dredging machine to clean the sand, as well as allow as much filth as possible to run over the edge of the bag or bucket before emptying it into the barges. The sewage smells even when the mud is dry, and turns the sand black, 3647–52. Samples are sent to the firm to enable them to see the state of the mud, which has a most unpleasant smell, and they have just heard that the Gravesend sand was spoilt, being covered with filth to a depth of 18 inches, 3648, 3653–5. Dredging sand and dealing with the mud are two distinct businesses which the firm carry on, 3678. Before the year 1864 the mud was of a white colour, and had no smell, 3679–81. These accumulations of mud in different places form the mud-banks, which have been referred to by other witnesses. A barge sunk a fortnight ago was put ashore in four feet of mud, where a few years ago there was a clean hard shore, 3686–88. The accumulation of sand is caused more by the deposit from a flush, than from the sea sand brought up by the tide. There is no doubt that it fluctuates, but the increased traffic and consequent stirring up of the mud has nothing to do with it, because there are eight or nine feet of mud now where they used to get clean good sand, 3691–94. The deposit at North Woolwich has a coating of sewage on the top, which can be identified by the colour, 3695–8. The cost of the sand for building purposes has increased, owing to the distance you have to go to obtain it, but people prefer salt to sewage in the sand. Gravesend sand is very free from salt, owing to the fresh water coming down, which purifies it. The sand can only be obtained at ebb tide, 3706–12.

Effects upon Health in the Neighbourhood of the Main Outfalls.—For two summers, in July 1880 and 1881, when the temperature was so high, the smell affected his health, and he was very poorly, 3668. It produced sickness and unpleasant feelings, causing him to vomit, 3683.

### Captain MICHAEL WILLIAMS.

Captain of the "Goliath" dredger.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Is stationed in Long Reach, where he has been for a year and a half. Prior to that was in Erith Reach, 3713–15. Is employed dredging for ballast, and gets good gravel now, but at times finds a good deal of "soil," particularly in the neighbourhood of the "Cornwall" training ship off Purfleet. The mud there is eight to twelve inches deep, 3716–24. When he finds the mud dirty he shifts his position to get more into the stream and avoid the sewage deposit, 3725–36. In Erith Reach there is a deposit of nearly two feet of sewage matter, which is sometimes very offensive, 3737. In Long Reach they are obliged to keep out in the stream to get clean ballast, 3738. Since he began to dredge, the mud and stuff on the banks has increased, and when stirred up it is hardly endurable, the smell is so bad, 3739–53. The "Goliath" is about 30 horse-power, and raises, on an average, 3,000 tons of ballast a week when working. The amount raised, however, depends on the demand, 3754–64, 3768. If there is a great demand for ballast, as much as 5,000 tons to 6,000 tons have been raised, 3774–5. There are several other dredging machines at work in Long Reach, which probably do the same amount of work as the "Goliath," 3769–73. Certain restrictions are imposed by the Conservancy as to the distance the dredgers must keep from the shore, because it is supposed that dredging damages the embankments. At present they are not allowed to go within 900 feet of the banks, 3776–82.

### Captain JOSEPH RICHARD WHITEHORN.

Captain of the "Hercules" dredger.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Has been on the "Hercules" 27 years, which is dredging for gravel now between Greenhithe and Purfleet. Before that, used to dredge in Erith Reach. They were stationed there for 10 years, but had to leave on account of the gravel becoming so mixed with "sewage matter" that the lightermen would not take it. It is obliged to be clean, as it is used for

## Captain JOSEPH RICHARD WHITEHORN—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

making concrete, 3783–93. Has tested the gravel by the smell and colour, which was very black. It was quite different to mud, and smelt of sewage. It was also mixed with sand, 3794–3801. Used to work opposite the sewer, in Halfway Reach, at one time, and only came to Long Reach about six months ago, 3802–5. Is in the service of the Trinity House, 3806. Before the outfalls were opened they dredged in Barking Reach, and got very clean, but rather fine, sand. There was no mud with it. Had to leave there 12 or 14 years ago, but they keep shifting up and down to try and find good gravel, 3807–13. The exact place where they now are is on the south shore off Little Powder-monkey Creek, where there is a good bit of ground for dredging purposes, 3814–15. Cannot get good clean gravel above Erith now. They tried at Dagenham two years ago, and only got very soft stuff of a bluish colour, all mud and sewage, which smelt nasty, 3816–22. It was just off the outfall, 3828–30. The Thames Conservancy settles the dredging stations. They cannot go where they like, 3832–3. Dredged a large quantity of stuff away in Halfway Reach. They average about 2,000 tons a week, 3834–7. The Dagenham Shoal, which has been dredged away, contracted the channel and depth of the water. In 10 years the depth of water was increased from 16 feet to 28 feet by the dredging, and mud began to accumulate, 3838–52. The spit of land at Coldharbour Point was dredged away, and the result was that the channel on the north side of the river was greatly deepened and widened. Wherever gravel is clean, the dredging machines go, rather than to shoals, 3853–71. In Long Reach they get clean red gravel, with some sand in it on the north and south shores. They are not allowed to work in the channels on account of the large ships coming up and down, which would be impeded by them, 3882–4. Has not found any sewage matter or mud in Long Reach with the dredger below Purfleet, 3885–91. Wherever there is an eddy-tide there is always a settlement of mud, and has seen it on the shore below Purfleet, 3892–4.

Offensive Odours.—When the sewage matter is discharged from the outfalls it comes out quite as black as ink; and on a summer morning the smell is "faint," and has driven him from the deck, and he has had to remain below. The "muck" with the sand has a similar smell, and can be detected immediately, 3822–7.

## Captain WALTER SHEPHERD.

Captain of the Steam Tug "Wildfire," belonging to the East and West India Dock Company.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river over 40 years, and since the outfalls were opened it has been in a very bad state, owing to a lot of refuse from the sewers floating about, which "smells odious," 3895–3900. Has often seen lumps of sewage floating about, but not lately, 3927–9. Is engaged daily in towing barges down to near Erith, and finds plenty of refuse in the water there, which throws off a bad smell, and is noticeable all the year round, 3938–55.

Offensive Odours.—There is a regular stink from the river, which is worse in hot weather than in cold, 3900–4. From Blackwall down to Erith the smell can be detected, and it is worse at some times of the year than at others, 3949–58.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The mud on the banks of the river is black and greasy, with a bad smell of sewage. The deposit has increased in Halfway Reach, as there is not so much water there as before the opening of the outfalls. The deposit is sewage, without doubt, as, when picking up the anchor, it is covered with it, 3917–26.

Injury to Fish.—Has seen eels floating dead on the water at certain times of the year. They come down with the land water, and on reaching Crossness are smothered by the sewage, 3930–3.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The smell from the sewage at Crossness has not affected his health in any way, but at times has felt sick from it, 3916.

## Captain WALTER SHEPHERD—*continued.*

Set of the Tide.—The sewage would go down on an ebb tide as far as the lower part of the Hope, and would return on the flood to Crossness or further. The ebb tide runs down for seven hours, and is stronger than the flood, 3905–13. Has drifted down with barges on the ebb, but has not made any observations or experiments to test the strength of the ebb and flood, 3934–7, 3915. Cannot with any degree of certainty speak as to the extent of the drift of the tide, as he is more in the habit of making short trips than long ones, 3959–61.

## Mr. AUGUSTUS ROBERT EDMUNDS, Blackheath. Barge Builder.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river for 50 years, and since the outfalls were opened the upper reaches from London Bridge to Limehouse have become purer, and the lower reaches have become more foul year by year, and the smell, more sickening than a closet smell, has increased, 3966–74. The water, when stirred by the steamers, becomes black as ink in colour between Limehouse and Gravesend, 3993–8. The smell of the mud and the water are all bad, especially at the outfalls and at Gravesend, 3999, 4000. Has continually seen slime on the top of the water, which has increased the last year, and his men have picked up lumps of sewage, 4011–13. Goes down to Gravesend four or five times, both on business and for amusement, during the summer, 4014–16.

Offensive Odours.—The bad smell which existed on the upper reaches of the river before the cholera is now to be found in the lower reaches, and is increasing yearly. It is a closet smell, but weaker and more sickening, 3972–4. The smell from the mud in the summer time is exceedingly offensive, especially at Cubitt Town, 3984–6. It is perceptible everywhere in the summer time, 4019.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—His works are at Blackwall Point, East Greenwich, and the mud about there is brown on the top and black below. It is very thick and stinks. About the piers the deposit is the same, but it improves as you go higher, 3979–83, 3987–8. Thirty years ago the mud between London Bridge and Limehouse was the same as it is now lower down, while below it was lighter in colour. Thinks the brown coating is due to the action of the atmosphere, but, not being a chemist, can give no reason for it, 4021–6.

Effect upon Health in the Neighbourhood of the Main Outfalls.—In summer every morning feels unwell as soon as he reaches the river, and suffers from loss of appetite, and faintness from want of food in consequence of his inability to eat anything until the evening. This happens for weeks together, 3975–8. Thirty years ago some of his workmen were ill from the smells, but has not lost any men through death, 3989–92.

Set of the Tide.—When serving his time as a lighterman, has gone down drifting on the ebb tide from Crossness to Gravesend, and come up on the flood to almost the same point. Concludes therefore that the sewage would drift to the same extent, 4001–10.

## Mr. GEORGE SAUNDERS, Erith.

Foreman to Messrs. Beadle Brothers.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has lived near the Thames for 21 years, and been in Messrs. Beadel Brothers, employ for that time, 16 years of which he has been foreman, 4029–31. His duties are to work on the wharf and about it. Most of his time is spent alongside the river, 4032–3. There is a great difference in the river now to what it was before the outfalls were opened The water is much thicker and more dirty, and there is a great accumulation of "sewage stuff" in the berths where the ships come, and they have great difficulty in keeping them clean. Can tell that this accumulation is sewage by the nasty smell, 4034–9. One of their barges sank in the river two years ago, and when raised she was in a "fearful state," having a lot of sewage mud in her, 4040–3. She was under water only two days, 4051.

## Mr. THOMAS MARSHALL, Erith.

### Wheelwright, and Sexton of Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been sexton of Erith for fourteen years, and has had considerable experience in the condition of people drowned in the river during that time, 4086–91. Remembers the "Princess Alice" disaster, and "had to do" with about thirty bodies. Some were brought ashore the same evening—ten or so—and they were in a very dirty condition. The pockets and clothing were one mass of mud (filth it looked like), sewage by the smell, 4092–100. For a week bodies were brought ashore daily, and they were in a very much worse condition, the smell being greater the longer they remained in the water. The smell was very horrible, "almost as bad as a bad privy," 4101–05. Fourteen years ago bodies were not in such a foul condition, nor so full of muck and mess as they are now, 4106–08. Bodies drowned in other waters have nothing the matter with them more than an ordinary corpse, no sewage deposit on them. The state of a body depends on the condition of the water from which it is taken, 4109–14.

Offensive Odours.—The accumulation of sewage mud on the berths has a very nasty smell, especially in the summer. It is like the smell from the discharge of the sewers, 4037–8, 4067–8. Has never noticed any smell coming from the Erith sewage, which is discharged about one hundred yards from the wharf. Only a part of the Erith sewage is discharged there, 4069–80.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There is a great deal more mud deposited in the berths now than in former years, for where one man was occasionally required to keep the berths clean, he is now regularly employed, and sometimes three or more are called in to assist. The mud is a kind of sewage—black mud, 4048–50.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has had several men laid up during the last few years, more frequently also than formerly. A club to which the men subscribed, and which was self-supporting, now requires help to keep it up, owing to the increased amount of illness amongst the men, 4044–7. The men work in the mud more than they used, but he cannot say that the illness is caused by the smell from the river. Three men are laid up at the present time, 4054–64.

## Mr. RICHARD JOHN NAYLOR, Woolwich.

### Ironmonger and Overseer of the Poor.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has lived at Woolwich 17 years, and has known the river for more than 30 years, 4118–19. The river is in a much worse condition since the outfalls were opened in 1865. When the tide begins to flow a thick muddy substance comes up with it, and the smell in hot weather at times is intolerable, 4120–22. The bodies recovered after the "Princess Alice" disaster were in a filthy, blue-black state, as if they had been black-leaded, and shiny. He attributes this to the action of sewage matter. There were nearly 500 bodies in this state, 4123–7. Has occasionally seen bodies recovered from other rivers, but very seldom. They presented a natural colour, and as a rule were covered with weeds, but in the Thames the clothing was filthy and covered with a slimy matter, 4127*a*–8. The whole of the sewage from North Woolwich is discharged into the Thames. It is collected in a large reservoir, which was constructed by the Metropolitan Board of Works at a cost of 1,500*l*., under Henley Road, North Woolwich, and is discharged at each tide into the river by the opening of a penstock at low water. He believes the northern outfall discharges the sewage within the metropolitan area, which is contrary to the Act of Parliament. The sewer connected with the reservoir is a few yards above the North Woolwich landing pier, 4130–5. Has noticed a good deal of drainage coming out of the sewer, which is opened every 12 hours as the tide suits, by a man who is in the employment of the Woolwich Local Board of Health, 4136–8. A considerable amount of drainage comes out of the sewer, as there are about 250 houses in North Woolwich parish and nearly double that number in East Ham parish at that particular spot, 4139. Was called on, as overseer, to bury the unclaimed dead at the time of the "Princess Alice" disaster. The accident occurred on a Tuesday, and he saw the bodies on the Saturday following. Most of them had been taken out of the river on the Saturday, but some were in the river upwards of a week, which were not identified, 4148–54.

## Mr. RICHARD JOHN NAYLOR—*continued.*

Popular Evidence as to the foul State of the Water in the River near the Main Outfalls—*continued.*

Offensive Odours.—The sewage work at North Woolwich is very offensive and causes a considerable smell, which is augmented by the smell from the northern outfall, and the smell from the sewage deposit on the mud which he has experienced to a considerable extent, having frequently to cross the river on business, 4140–7.

## Mr. JOHN WILLIAM SHOWELL.

### Deputy Harbour Master, and Inspector of Nuisances and Explosives, Greenwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—His district lies in the lower part of the river, more particularly from Greenwich to Greenhithe and Long Reach, 4304–5. Has known the river all his life, and remembers the outfalls being opened, 4306–7. There has been a great difference in the state of the river since then. It has become polluted from the sewage; it is a different colour, and much thicker. There is also a great deal of filth and sewage with it, which causes a great smell, 4308–14. There is no discharge into the river from the chemical, gas, or manure works, and if he saw any it would be his duty to take samples. Has however had no occasion to do this during the last few years, 4335–8, 4344–7. In fact the only discharge which he knows of during the six years he has been inspector, has been from the sewers of the Metropolitan Board, 4353–7. Inspected the pipe coming from the gas-works at Beckton only a fortnight ago in the course of his duties, about half ebb tide. Could tell from the colour of the water, and the mud on the shore, whether any offensive matter was being discharged from the pipe. Has never seen anything offensive coming from it, 4358–93. Pure water runs out at low-water, 4397–4401. The pipe is intended to carry off the land drainage water, and there is less water discharged in dry weather than in wet, 4402–4.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There has been no alteration in the mud up and down the river on the banks, but it is a different colour to what it was before the outfalls were opened. It is black filth, 4315–9. The sewage discharged from Crossness settles about the lower part of Halfway Reach and off mid-channel, and then down Erith Bight. The deposit is like human dung, and it has increased a great deal during the last few years, 4326–31. From Barking there is a great settlement of mud or filth right away down to Dagenham, of just the same description as that from Crossness, 4332–3. In some places when he has let go his anchor he has found eight to ten feet of slime and slush, and has not been able to reach the anchor with his boat-hook. It formerly used to be hard shores, 4341–3.

Set of the Tide.—Anything put into the river at Crossness on a neap tide would drift down to the upper part of Gravesend Reach, and would return on the flood to Tripcock Point, which is above Crossness. The flood is stronger than the ebb, but he has never made any experiments on the tides, 4321–5, 4396.

Injury to Fish.—The sewerage and filth discharged into the river have, in his opinion, killed the fish, 4339–40. Forty years ago he used to have "to do" with the Dutch eel-boats which came up the river, but about 30 years ago they went down to Stoneness Point, on account of the water going bad, 4348–52.

## Mr. WILLIAM EVANS.

### Under-waterman, Woolwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—His duty is grappling for things in the river; and when he puts his grapplings overboard the state of the river is such that he can go but very little distance before they are choked, and are no good to him. There is a lot of filth underneath, "sewage sort of stuff which is nothing but slime and "stinking filthy mud." which, when moved, comes up like a lot of oil on the water, and the stench is hardly bearable in summer, 4408–10. Has seen long red worms several inches in length on his grappling ropes.

## Mr. WILLIAM EVANS—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

They are not fish-feeding worms, but eat all the substance of the rope if it is left in many days, and rot it, 4411–14. On a moonlight night, in rowing from Grays Blackshelf up to the outfalls, has arrived there about two hours before high-water, and the discharge from the outfalls has turned his boat aside, 4415. Was fishing for shrimps that night down at Greenhithe, 4423–5

Offensive Odours.—When steamers go up and down the river becomes black as ink, and the stench is very bad indeed in the summer time.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Has seen a boat in trying to anchor in the Government moorings at Woolwich (where the "Fisgard" used to lay) get aground, and the channel is now on the north side of the river instead of on the south as it formerly was.

## Mr. FREDERIC BOWREMAN JESSETT, F.R.C.S.

Medical Officer of Health for the District of Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has lived at Erith between 12 and 13 years. Of late years the condition of the river has been very bad. When first he came to Erith men use to bathe off the end of the pier at high tide in the early morning; but now such a thing would be impossible, owing to the contaminated state of the river from the sewage from the outfalls, which has increased considerably of late years, 4429–33. Last summer, when yachting, on returning with the flood tide, there were large masses of sewage (as large as the table in front of him) floating about, and the ladies were sick and unable to eat owing to the atrocious smell arising from the sewage. He was then off Purfleet. Has often noticed this on the river, especially on the mud at low tide, when the gas can be seen bubbling up constantly, 4460–64.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has had occasion to treat persons for illness which has been chiefly due to the contaminated state of the river. About the middle of last year a man recently appointed to the Thames Police Yacht had not been on board above a week before he was seized with most violent diarrhœa and sickness. He was treated on the yacht for several days, but as he got no better he was removed to the shore, and in two days became better, and very shortly after recovered, 4434–42. A number of men who work at the wharves removing the mud to keep the way clear for the vessels to come up, have come to witness from time to time suffering in the same way as the river policeman. Has attended men from the ballast wharves for the same cause, 4443–6. There has never been any epidemic of this illness, but has had a fair number of cases amongst the workmen on the river banks, 4447–8.

Health of Erith.—That Erith is a healthy place, notwithstanding the state of the river is due to several causes. One is that the place is new, the cottages are nearly all recently built, and in Erith proper the greater number of cottages are drained. Nearly all the wells have been closed, and the Company's water laid on. The soil being gravel adds to the healthiness. There have been several cases of typhoid fever in the town, and they were chiefly in houses near the river, whose wells were found to be polluted with sewage. In some cases the fever occurred in houses which had cesspools, but there has been no typhoid for some few years in the parish of Erith, 4449–50, 4452–4, 4456–68. The Registrar General's Returns for last year showed a lower average for Erith than for London; but it was an exceptionally healthy year, and Erith is a country place, and not a town like London, 4465–7.

Mortality in Erith.—The death-rate of Erith has not been decreasing year by year. In 1878 the number of deaths in Erith was 147. In 1879 and 1880 the number was 165 each year, and in 1881 an exceptionally low rate, viz., 114 deaths. The death rate in 1880 was 14·63 per 1,000, 4475–81. (Makes an annual report, and will hand in his report for 1881 to the Commission, 4471–4, 4482.) The death rate for 1881 was 11·1 per 1,000, 4483. The deaths from typhoid are very few, and there has been a great diminution in all deaths from infectious diseases or typhoid, owing to the improved sanitary arrangements of the place. There has only been one death from diptheria to his knowledge, 4484–7.

## Mr. FREDERIC BOWREMAN JESSETT—*continued.*

Effect on Wells near the River.—A number of wells have been closed every year for the last six or seven years, in consequence of their being polluted with sewage. Has no doubt, but is unable to prove it, that the wells contiguous to the river are tidal wells; that is to say, that at low tide they are empty, and at high tide they are full, so that where the water can run off, the sewage might very easily soak back and contaminate those wells. The water in many of them has been analysed and condemned, 4450–2, 4457. The wells which were closed were principally situated in the High Street. A well in West Street, which was close to a cesspool, was not closed, although the water was twice analysed, and he strongly recommended its being closed, 4488–95. The analyst's reports can be produced if necessary, 4496–7.

Drainage of Erith.—In Erith proper the houses are nearly all drained; but at Abbey Wood, Belvidere, and Northumberland Heath the houses have cesspools, 4453, 4469, 4470.

## Mr. RICHARD ARMITAGE.

Fisherman, Woolwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is 66 years of age, and has known the river since he was apprenticed, 50 years ago, 4500. There is a great difference between the river now and what it used to be before the outfalls were opened, 4501, 4502. It is very bad now, and at certain times of the tide the water is quite black and smells very bad indeed, 4509, 4510. There are no worms to be found in the mud now, nor any above the Lower Hope. Any person who says there are "rope-eating" worms higher up is wrong, as he has tried to find them. They were used as bait at one time, and would be glad to find them now, 4525–8. Has occasionally tried grappling and dredging in the mud, but it is no use, for anything which is picked up by the grapnel is all black and slimy, 4534, 4535.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The settlements along the shore are quite black and very slimy. From Dagenham, round Erith, through Erith Bight to Long Reach, there are deposits of mud; but the worst place is at Erith, where the banks of mud rise up seven or eight feet high. They have increased very much indeed of late years, 4511–19. The thickest part of the "deposit stuff" settles along the shore, and nothing can live near it. It has killed all the worms, and if the fish came up they would not live, 4522.

Set of the Tide.—Anything put into the river at Crossness would drift to Gravesend on the ebb tide, but has never practically tested this, 4520–1.

Injury to Fish.—Twenty years ago there were plenty of fish at Woolwich, and has caught them there; but now can get none above Gravesend. Since the southern outfall has been opened they have gone away, and the sewage water would kill them if they came up, 4503–8. Sells the eels he catches at Erith, but has to put them in a corfe to take them there, not into the water, 4531–3.

## Mr. JAMES ADAMS, Grays.

Master of the barge "C. T. F."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Lives at Grays, on the north shore of the river, and has known the river over 40 years, 4536–9. Since the Crossness outfall was opened the river has become very filthy. Anchors and chains are smothered with filth, and it takes a good deal of time to sluice them with water to remove the muck on them. The smell is dreadful, "enough to knock you backward," 4542–4. At Crossness there is an anchorage for barges, and they lie there for seven hours waiting for the flood. The discharge from the sewers turns the paint all sorts of colours as they lie there. His business is to carry cement in his barge (which is a sailing barge), from Purfleet to the Docks and the Pool, and he goes down the river at all times of the day or night as the tide suits, 4552–3, 4561–3. Can sail over the tide frequently with a fair wind, 4564. A fortnight ago, coming from Beckton, the sewage was being discharged in large quantities as he passed about three o'clock in the afternoon, sufficient to turn the barge away from her helm. For 100 yards all round

## Mr. JAMES ADAMS—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

from the outfall of the sewer the river presented the appearance of being nothing but grease, 4565–73. The river at the northern outfall is in quite as offensive a state as at Crossness. Anchors and chains are covered with the same filth, 4575–84. Has never noticed a sewer pipe coming from the Beckton gas-works, 4585–6

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Years ago, before the outfalls were built, ships drawing 14 to 15 feet of water used to lie just below Crossness, and now there are not five feet of water there, 4540–1.

Set of the Tide.—Sewage discharged at half flood tide would drift up to Blackwall. If discharged on the ebb. it would go down as far as Long Reach below Purfleet, but he is unable to say how far it would return on the flood, 4547–51.

Discharge of Sewage from the Main Outfalls at improper Times.—Has frequently noticed the sewage being discharged from the outfalls at about half flood, or three hours before high water, 4545–6. Has seen it two or three times a week, 4554. A fortnight ago, as he was coming down from Beckton, he saw the sewage being discharged at half flood in large quantities, with sufficient strength to turn a barge from her helm, 4555–9, 4565–7, 4570–3.

## Mr. THOMAS BROWN, Gravesend.

Master of a barge belonging to Messrs. Knight, Bevan and Co.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—For 44 years has been master of a barge running from Northfleet to London, 4589. Remembers the outfalls being made, and since then the river has been in a most filthy state nothing but impure matter. When he heaves up his cable and anchor it is blacker than his clothes. He refers now to Halfway Reach. Erith Reach is just as bad, and the water is as black as ink, 4592–5. The smell when the sewage is being discharged is enough to knock you down, 4596. His barge is a 90-ton sailing barge, and he is in the habit of loading up with coke at Beckton. Has seen a discharge from a sewer pipe at the gas-works which is only water, clear but yellow. The colour he attributes to some process connected with tar, and there is no deposit in the water, 4616–7, 4622, 4640–2. Has not seen this discharge for a fortnight, but often during this summer and last year, 4623–5.

Offensive Odours.—The discharge of water from the Beckton gas-works is not very pleasant, but it is not so bad as the sewers, 4618–21.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Where ships used to lay afloat Halfway Reach in 12 to 13 feet of water, he cannot now float his barge, and there is a great deal of mud on the anchor, 4591, 4611–2. The stuff deposited on the banks of the river is nothing but stinking filthy matter, 4606–7. It is the discharge from the common sewers which causes this matter to be lying at the bottom of the river, 4608–9. There is not much mud in Halfway Reach off Crossness, because below the creek the wall is all stonework, 4610.

Discharge of Sewage from the Main Outfalls at Improper Times.—Has seen the sewage coming out of the Crossness outfall two hours before high water "scores of times." Coming from Beckton the sewage "slews" his barge all on one side, and the water is a body of grease on the surface, while underneath it is quite black, and of a different colour to the other water, 4597–600, 4643–5. The stream of sewage is so strong that the rudder of a barge has to be put over to port so keep her head straight, 4367. "It is not in his power" to complain of this state of things, 4638. Had he only known he would be questioned on these points he would have brought his notes to enable him to give more accurate information as to dates and hours, 4646–8. The difference between high water at London Bridge and the outfall would be from 30 minutes to 40 minutes, 4648. Goes up and down the river continuously, 4649.

Set of the Tide.—Has traced the discharge down as far as below Erith, and has seen it coming down, two or three hours before high water. Has seen very little sewage in Northfleet Hope at the anchorage, 4601–5.

## Mr. ROBERT PLUMB, Gravesend Fisherman.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is 57 years old, and has known the river for 47 years, as he began to work for his father when he was 10 years old, 4651. For the last 14 years the river has been in a bad state, 4666–7.

Injury to Fish.—Fourteen years ago he used to fish in Long Reach for eels, and there were plenty to be caught there. At "dead tides" the eels would be between the two waters, but with the spring tides the bad water would come down, and then they had to take the eels out of the wells to save their lives, 4653–4. Catches fish and shrimps mostly in Sea Reach, but they are obliged to boil them before they arrive at Gravesend as it is impossible to keep them alive now. The foul water kills the fish, 4660–6. Formerly the eel-boats took the fish up in wells at certain times in the day, but now they are packed in boxes at Hole Haven and sent to London in that way. This has been the practice for some years. Has been driven down from Long Reach for 12 or 14 years, 4673–6, 4652.

Set of the Tide.—Believes the ebb tide to be stronger than the flood tide as there is more slack water round the points at flood tide. There is not much difference between the flood and the ebb as to the strength of the tide at the top and the bottom. Has drifted with the tide with a trawl overboard from Gravesend to Leigh Middle, but then there is scarcely any tide at the bottom, 4657–9.

## Mr. GEORGE MARTIN.

Free Waterman. Gravesend.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river for nearly fifty years, and remembers when the out falls were opened, 4679–82. Prior to the opening of the outfalls the water used to be drank in Halfway Reach and at Barking, and it was the custom to fill their water casks there. They have not been able to do this since the outfalls have been in existence, and the river is in a filthy state, being filled up with mud, and slush and muck which "stinks filthy," 4683–8. The colour of the water is as black as a coal, 4692. Has only seen the outfalls opened once when going up and down the river, and that was just about high water. The stench of the sewage was something horrid, 2691–2. Has noticed lately that the water about Greenwich has been very good, which he attributes to the fresh water, but below it is very bad, especially from Halfway Reach to Erith and Purfleet, 4704–6. The water between these places is bad and smells beastly, and can prove it to the Commissioners if they went down there as far as Long Reach, 4717–19.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—On the banks of the river there is a deposit of filthy muck which has quite a filthy stench, and it is much worse than it was a few years ago, 4689–90.

Offensive Odours.—There is a very filthy smell from the river and the deposit of mud on the banks between Halfway Reach and Purfleet as far as Long Reach, 4688, 4689, 4693, 4717–19.

Injury to Fish.—Knows but little about fishing, as he has only been in the habit of carrying fish from Gravesend to Billingsgate. He takes charge of the fishing smacks as waterman, and has been engaged in this work for over 38 years, 4696–9. Has seen fish up the river in corves, which are boats constructed with holes in the bottom on purpose to carry fish, but this was 16 or 17 years ago. Is quite positive that it is not done now, as the fish would not live in the water, 4700–4 The fish for the London market are shipped from the north sea boats into cutters which bring them up the Thames. They are dead, and packed in the hold, 4709–14. Has nothing to do with live fish, 4715–16. Eels only, he believes, will live if brought up in corves at low water by tugs through Halfway Reach, provided also that no sewage is being discharged at the time. They do not feel the effects of the sewage at low water so much as high water, 4720–29.

Set of the Tide.—Sewage if discharged on the ebb at Crossness would drift down to Gravesend Reach, but has never had any opportunity of testing this. He has smelt it as far as Erith and Long Reach, 4693–95.

## Mr. JOHN TALL.

Waterman and Lighterman. Gravesend.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been on the river for 36 years, and there has been a great change for the worse in the river since the outfalls were opened between Erith and Woolwich principally. It is now dirty and filthy, 4732–6. Has seen the sewage discharged from the outfalls a great many times, at all times of the tide, but as he passes up and down six times a week he cannot state any fixed time for the discharge, 4742–4.

Offensive Odours.—The deposits of mud on the shores stinks very much. It has a very nasty smell, 4741, 4748–50.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The mud is thick and black, and you are able to tell when you get into the sewage by the filthy condition of the chain you ride by. It turns it quite black, 4737–40. The mud on the shores is like a "soft slough stuff, more like slime," and it is increasing fast in Halfway Reach, 4745–51.

## Mr. WILLIAM BROWN.

Fisherman. Gravesend.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river for 56 years, and is now master of a small fishing boat, 4754. Since the outfalls were opened there has been a very considerable change for the worse in the state of the river. In the winter seasons fishermen could get a living, but now nothing will breed in the river, 4755–9. Is unable to say what is the matter with the river, as he does not know what goes into it. There is not much difference in the look of it, except in summer, and has not noticed that it has any smell as he has not been above Greenhithe for some time, 4760–6.

## Mr. HENRY EVANS.

Under-waterman and Sand dredger, Woolwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has lived at Woolwich all his life, and has been up and down the river two or three times a week ever since he was a boy, 4769, 4773, 4776. Since the opening of the outfalls there has been a vast difference in the state of the river as regards the refuse and rubbish at the bottom, and also as regards the sand that is dredged. At Jenningtree Point, where he used to work every day, thirty years ago, the sand was always good and clear; but of late years it has been very filthy and dark. It is now alternate streaks of sand and streaks of greasy black mud, which is scarcely of any use. In warm weather the men can scarcely work it, on account of the stench and refuse under the sand, 4771–2.

Offensive Odours.—Has perceived a very bad sickly smell from the river, especially from Barking Creek up to the northern outfall. The deposit of mud mixed with the sand smells also very bad, 4772, 4783–4.

Discharge of Sewage from the Main Outfalls at Improper Times.—Has frequently noticed the sewage discharged, from the southern outfall in particular, at two hours before high-water, when rowing down from Woolwich. On the north side there was broken water, and on the south side the sewage made the water smooth. The current from the sewage has turned his boat's head away, 4774–81.

## The Rev. JOHN McALLISTER, Heathfield, Plumstead.

Vicar of St. Nicholas, Plumstead, and Member of the Board of Guardians.

Plumstead Parish and District.—The population of Plumstead is about 15,000, and the northern boundary of the parish extends for two miles along the river. Part of the parish is high ground, stretching from the marshes; and the Government range, which is in the parish, is marshy ground, 4789–92, 4866–69. The marshy ground lies between the railway and the river, and the higher ground slopes up towards Plumstead Common, 4942*a*. His house is half a mile from the marshes, and about three miles as the crow flies from Silvertown, 4942–3, 4945. Has lived in Plumstead for 19 years, 4786–7, and is a member of the Board of Guardians, 4875.

## The Rev. JOHN McALLISTER—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is in the habit of going on the river frequently and by the river, and has paid some attention to the question of how far the Thames has been affected by sewage from an amateur's point of view, 4793–4. Has frequently noticed sewage in the river above and below his parish, but more especially in the part which is co-terminous with the parish, which lies between the two outfalls, 4795–6, 4798. Has seen it floating up and down the river; frequently going up, and at a time when the sluices were shut, as he understands the rule is to open them only when the tide is running towards the sea, 4799–801. Was not aware that there were places of any magnitude on the Thames where the sewage was permitted to flow into the river; for example, Erith; but has seen the matter that discharges from the Beckton Gasworks, and the sewage from Barking Creek, 4900–5. Does not remember the river before the outfalls were opened, 4852.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Has frequently seen deposits on the sides of the river, and has examined them carefully by inspecting the mud. It is evidently human excrement in a state of decomposition, full of worms, 4802–5. Has noticed these large deposits of worms every summer for the last nine or ten years, but his attention was not called to it before that time, 4841–2, 4849–51. In appearance, these worms are red, and vary in size from two to three inches in length to very small. They were to be seen in very large quantities, but he does not draw his inference that the deposit was sewage from the presence of these worms, but from its smell, 4843–8. Has never made any analysis of the mud, nor examined it microscopically, but it differs from mud found in other parts of the river in possessing a very offensive smell, which, so far as his knowledge extends, is inseparable from sewage in a certain state of decomposition, 4851–6. Has noticed a smell in mud taken from the bottom of a pond, but it is different to the smell from the river mud. If he were given a sample of this mud to which he has been referring, and one of pond mud, he believes he would have no difficulty in discriminating between them, 4856–8. The mud which is contaminated by sewage is deposited in little creeks by eddies, and in more open parts the sewage is not deposited, and ordinary mud will be found there. Is unable to point out any particular spot where sewage mud has been deposited, but has noticed and examined it between Crossness and the Arsenal at Woolwich, 4859–65.

Offensive Odours.—The smell from the deposit in a state of decomposition has a very offensive smell, especially in summer, 4807. It is noticeable all over his parish, even at a distance of three or four miles from the river, and he can discriminate between the smell of the chemical factories and the smell from the river as easily as he can detect the difference between the smell of an onion and a boiled cabbage. The sewage smell is quite distinct from the other, 4808–13. The smells are worst when the wind blows from the north-east, from the middle of March to the middle of April, and from the middle of September to the end of October. The smell from the sewage is very strong and very disagreeable, 4814–16, and can be detected any year at the times he has stated all over his parish with a north-east wind, 4895–9, 4917–21. A smell is emitted from the discharge at the Beckton Gasworks and at Barking Creek, but it is not so bad as the smell from the outfalls. His attention, however, has never been specially directed to that part of the river, 4904–16. Has never heard any complaints made of offensive odours proceeding from the chemical works by his parishioners or the inhabitants of Silvertown, 4946–9. Has noticed the sewage smell at East Wickham House, the residence of Mr. Jones, which is more than three miles from the outfall, 4950–1. His attention has been directed to the nuisances evolved from the factories on both sides of the river, and though he has made frequent complaints on the subject, the guardians have taken no particular steps in the matter, nor has the medical officer either. The general impression on the minds of everyone to whom he has spoken is, that it is no use trying to remedy this evil when the nuisance of the Thames is so great. The matter requires to be dealt with as a whole, 4922–31.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has taken particular interest in the question of health as affected by the smell from the

## The Rev. JOHN McALLISTER—*continued.*

### Effect upon Health in the Neighbourhood of the Main Outfalls— *continued.*

sewerage, and has noticed that foul air, when it comes over the parish, produces the same effect on the inhabitants as a hot wind does on vegetable life under certain conditions. The *vis vitæ* sinks directly, and all feel it, himself included. His vitality is not as powerful when under the influence of these smells as it is at other times. Has had scarlet fever in his house three times while living at Plumstead, and has lost two children from it. Though holding an opinion on the subject, he would not like to commit himself positively to the fact that the sewage was the direct cause of the fever 4817–21. The north-east wind, when blowing over marshes in which there was a great deal of sour half-decomposed water, would probably have an injurious effect on the population, but if the marshes were flat lands and well drained they would not have that effect. The Plumstead Marshes are supposed to be well drained, and he knows of nothing of an injurious character that could emanate from them, 4870–3. Has never known of a real case of ague in Plumstead, since he has lived there, 4874–7. The general health of the district, as compared with that of the whole of the metropolis, is not so good as some, though perhaps as good as others, 4878. Has had some cases, though not many, of typhoid fever in his district, 4893. Has noticed in the cases of certain patients, in whom he is interested, who are suffering from depression of *vis vitæ*, that the pharmacopœia of medical men to whom he has taken these patients, generally consists of quinine, and this depression is on the increase, 4932–6. There is no local board of health at Plumstead, but the district board of works take cognizance of sanitary matters. Certain sanitary matters are referred to that board, such as complaints as to sewage, while certain other things are relegated to the board of guardians. There is a medical officer of health for the district, 4937–41.

Mortality of Plumstead.—His general impression is that Plumstead stands lower than most of the other districts, and about equal to some of the worst of them. From memory he cannot state what the death rate per 1,000 is in his district, 4879–83, nor can he say how much of the mortality of the district is attributable to zymotic diseases. Scarlet fever is always present, and he attributes the violent periodical outbreaks at certain seasons of the year very much to the poisoning of the atmosphere. Everything is done to isolate the cases and prevent the spread of the disease, but it is a very difficult matter to deal with. Is not aware that the medical officer has made any special report on the means to be taken to avoid the incidence of these epidemics of scarlet fever, 4884–8.

Effect on Wells near the River.—No report has been made by the medical officer specially on wells in connexion with cesspools, and on the pollution of water from contact with, or in the vicinity of, cesspools, 4891. The water supply of the parish generally is by means of artesian wells, which are supplied with water by the North Kent Waterworks, said to be the best water in the neighbourhood of London. His house is so supplied, and was at the time of the scarlet fever in his house, 4957–60.

Drainage of Plumstead.—The use of cesspools is supposed to have been discontinued long ago. The main drainage runs through the parish, and every house and street within its reach is supposed to be connected with and drained by the main system, 4889–90. The marshes are relieved of stagnant water by a perfect system of drainage. The Government undertake that part which belongs to them, and arrangements have been made to drain the other part by means of sluices, which are opened at certain times, 4961.

Discharge of Sewage from the Main Outfalls at Improper Times.—Has seen the sewage floating up the river at a time when the sluices must have been shut, 4801–32. Has also seen it going up the river on the tide frequently when he himself has been on the river and on the banks. Noticed it last summer in June and July, 4800, 4822–26. He saw greasy matter, conveying to his mind the same impression as a small stream of ketchup poured into brown soup, 4827, 4828. Has seen the outfalls opened and the sewage flowing into the Thames frequently. On these occasions he has been watching the river casually, with no idea that he would be called on to give evidence, 4829–37, 4952–6.

## Mr. HENRY PASSFIELD, Lambeth.

### Fisherman.

Injury to Fish.—Is 45 years of age, and has fished in the river over 30 years, 4963–5. In the first part of the year, up to August, he is in the habit of fishing from Sunbury to Hungerford Bridge, and also fishes lower down, as far as Lower Hope Point. It depends on the time of the year whether he fishes up or down, 4966–75. About five or six years after the outfalls were opened the sewage affected the river, and drove the fish away. Used to catch shrimps at Barking and in Halfway Reach, but what he fished for to get his living was eels, 4976–81. In Limehouse Reach, which is a few miles above the outfalls, no fish are to be caught, 4982–5. Flounders, dace, roach, and eels can be caught at Hungerford Bridge in August and September, but there are no fish at all between that point and Gravesend, 4986–90. Roach and dace being fresh water fish, are never seen below Hungerford, but eels are fresh and salt water fish. The eels caught up the river are a different class to those seen down below, 4991–8. In going to fish down below he puts different gear into the boat and fishes all the way down, 4999–5000. Never tries to catch fish between Hungerford and Gravesend on account of the sewage. Nothing will live there, 5001–6, 5008. Year by year, from five years after the opening of the sewers, the state of the river has become worse, and fishermen had to move down from Erith to Greenhithe, 5007.

## Mr. WILLIAM HENRY LEWIS, King William Street, Greenwich.

### Port Sanitary Inspector to the Port of London.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—The extent of the jurisdiction of the Port of London Sanitary Authority is from Teddington Lock down to the north-east corner of the Isle of Grain, and there are two other inspectors who share with him the charge of the district, 5011–11*b*. Has been engaged on this duty since 1873, the date of the formation of the authority, and is chiefly engaged between Greenhithe or Erith to Battersea. At times he is at the extremes of the district, 5012–14. His duty takes him on some part of the river every day, and since 1873 has noticed a most decided change in the river, 5015–17. During the summer of 1880, the river from Jenningtree Point to Cherry Garden Pier was in a very bad state. Black patches of stinking matter, which seemed to have been drawn up from the bottom by the heat, floated on the surface of the river, and when touched broke up. The size varied from six to eight feet in length by six feet in breadth to half that size. There was a very offensive smell with it, and this foul state of the river lasted through July to about the middle of August, when it was dispersed by a heavy rain, and was not seen again, 5018–28, 5040. In 1858 the river presented a similar appearance, 5029. Witness was at that time connected with the Dreadnought Seamen's Hospital, which was moored then off Greenwich, 5030–1. There was a greater amount of this foul stuff, and it lasted for a longer time. The patches extended over the whole width of the river, which was in fact a black ditch from Greenwich up to London, 5032–9. After 1864 the river seemed pretty good, but during the last six or eight years it has assumed rather a bad character, and has been getting gradually worse; blacker and smells badly, 5041–4. In July this year it began to be rather bad, but not so bad as it was in 1880, 5045–6. In 1880, when with Dr. Collingridge, the medical officer, he took samples of the water at the following places:—Jenningtree Point, Purfleet, by the "Cornwall," and at Charlton inside the "Warspite." They were taken on the flood, and the samples smelt like sewage, not like pure water, 5058–65. On the 30th June 1882, in company with Dr. Collingridge, he took some more samples. No. 1 was taken at 2.25 p.m., about half-an-hour after high-water, a few yards up Barking Creek. No. 2 was taken at 2.30 p.m. at Lawes' Chemical Works. No. 3 was taken at 2.35 p.m. at Barking, about 200 yards below the outfall, in a line with the sewage. No. 4 was taken at 2.50, at Halfway House Point on the south shore, about 30 feet from the bank off the surface. No. 5 was taken about 50 yards above the Crossness Outfall, at 2.55 p.m. No. 6 was taken at Crossness, over the line of sewage discharging from the outfall, at 2.59. No. 7 came from off the second jetty at

## Mr. WILLIAM HENRY LEWIS—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

Crossness Pumping Station, about 120 feet off the quay, at 2.59. No. 8 was taken at the West Kent Tanks, from the upper and middle reservoirs (about half from each), at 3.55 p.m. No. 9 was taken at Greenhithe, at 5.40, in a line with the causeway, close in shore. No. 10 was taken at Barking, at 7.10 p.m., at the sewer at low-water, the outfall running with great force; and No. 11 was taken from the bottom, close in shore, at 7.15, about 150 feet below the outfall, 5066–93. Except No. 4, these samples were taken below the surface, 5081. On the 28th July, 1882, between midday to 10 o'clock on the 29th July, he took 24 samples of water, which were submitted to Dr. Tidy. The place from which they were taken was about the same spot, viz., off Crossness Pumping Station. The depths varied from 3 feet below the surface to 18 feet below, when the sewers were discharging. There was a very great stink from the outfall all night. No. 1 was taken at 12 noon, near the upper outfall, about 3 feet below the surface, and 60 to 70 feet off the quay. Sewer running. No. 2 taken at 1 p.m., same place. No. 3 was taken at 2 p.m. from the bottom, 18 feet below the surface, near the upper outfall. No. 4 at same place at 3 p.m., when he came in contact with the wooden sewer. Water discoloured and warm. Sewer still running. Upper outfall stopped running at 4 p.m. till 11.20 p.m. when it began again, and stopped 3.30 a.m. At 2 a.m. the bottle caught in the outfall, and it was 15 minutes before it got clear. At 8.15 a.m. noticed the sewage returning on the flood, and traced it from the powder works up to the point at Crossness, and then over to Bridge's Powder Magazine, 5097–125. Has also taken samples of mud when the tide was on the turn, and noticed sewage then coming up. The three outfalls were running with great force, 5126–35. The mud samples were taken from opposite the clock, next the pumping station at Crossness, from near the upper outfall in a line with the jetty, and from between the Government Powder Magazine and the powder jetty, 5136–7. There are in his district a considerable number of outfalls discharging into the river quite distinct from the outfalls of the Metropolitan Board of Works, from which sewage flows. In Barking Creek there are one or two small affairs, but when passing up the creek you would not observe at any time any soil floating about it, 5149–53. The discharge from Beckton sewer is sometimes offensive. The size of the outfall is 18 inches in breadth by about 23 inches in length, and is oval-shaped, 5156–9. The largest outfall is at West Ham, which is, however, a small affair, and can only be seen at dead low-water. All the rest are "privies," 5160–4. It is part of his duty to make returns and report upon foul outfalls at stated times, and when ordered to do so by the medical officer, 5165. Roughly speaking there are at least 40 privies or closets at Poplar, and eight or ten at Limehouse, 5166–8. By a return he made, which is embodied in the Report of the Port of London Sanitary Authority, dated 15th December 1881, there were 187 foul outfalls on the north side of the river, and 182 on the south side of the river, 5169–74. Of these 117 on the north and 59 on the south, are said to be within the jurisdiction of the Metropolitan Board of Works, and in his return privies and closets are included under the head of outfalls. It does not mean sewers only. Rotherhithe, for instance, has 19 outfalls, which would, with one exception be closets for riverside houses, 5178–86. In Bow Creek there is a Metropolitan Board of Works sewer from which he has seen foul stuff coming out. Believes it to be a storm outfall, 5188–93. In Barking Creek there is only one sewer to his knowledge, but he has seldom seen it, 5195–8. Has continually taken samples of water and mud for many years, and has sent them to different gentlemen for analysis, 5192–201. Attributes the foul state of the river to general dryness of the year, and to the heat and drought in July, 5202–5.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—On the 28th June he took three samples of mud from the bottom of the river, 60 feet from the shore, and from 600 to 700 yards above the southern outfall, 5138–48.

Effect upon Health in the Neighbourhood of the Main Outfalls.—While out on the river on the 28th June taking samples, the fearful stink from the mud-

## Mr. WILLIAM HENRY LEWIS—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

bank near the outfall knocked up the boy who was in the boat, and he was ill for a day or two after it, 5119. The health of the sea-faring population on the river is generally good, and there is no epidemic of disease amongst them at present. Is rather proud of the healthiness of the Port of London as compared with other ports, 5174–7.

Discharge of Sewage from the Main Outfalls at Improper Times.—Has traced sewage in the river up to the lower part of Blackwall Reach frequently, and has seen it flowing up stream. The track can be seen distinctly as coming from Barking or Crossness outfalls, and he is able to distinguish that it comes from there, 5048–57.

Discharge from the Storm Overflow Outlets.—Is conversant with most of the storm overflow outlets, and has seen them discharging frequently both in rainy and dry seasons during summer time, at Blackfriars and at Deptford. Has noticed an offensive smell at those times from the river, and in the Broadway at Deptford. By the smell you can tell whether there is a discharge from the outlets without going on to the river to see, 5208–12.

## Captain JAN VISSER, Harlengen, Friesland.

Captain of a Dutch Eel Vessel.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is 51 years of age, and has been engaged in the Dutch eel trade since 1858. In the spring of the year he used to come up to Erith until March or April when they had to go lower down the river on account of the bad state of the water, 5213–22. In 1866 and 1868 the river had become much worse, and he found it necessary to lay in Hole Haven Creek, as they do now, both in spring and summer on account of the bad condition of the water, 5223–9. Twenty-four years ago the foul water was up at London, 5256.

Injury to Fish.—Eels could not live now in the river below Woolwich, because between Woolwich and Erith the river is foulest, 5230. Eels are brought up to London from Hole Haven in boxes in the watermen's boats. It is not possible to bring them up in the eel boats at any time of the year as they would not live through the foul water, 5231–3, 5239. The value of a cargo of eels varies according to the state of the market from 500*l.* to 800*l.* One boat carries 10 tons, 5234–8. In 1864 the eels had to be shifted during hot weather at Gravesend into boxes for carriage to London, 5242–5. In the early spring, or in the latter part of the year after much rain, eels are sometimes taken in the wells to Billingsgate, because the water is purer after continuous rain. He only brings part of his cargo up in the winter at a time, on account of the market being slack, and sells part to people who come on board to buy it, 5246–51, 5261–5. In the summer time when the water is bad the whole cargo is brought up in boxes, as was the custom in 1858. When they laid off Erith the eels were brought up in pots, 5252–5. If a cargo is brought up in the hold of a boat it is always towed up by a tug, as it then passes rapidly through the water. To go slowly between Barking and Woolwich the cargo would be killed by the water, as all the eels brought from Holland are alive, 5257–60.

## Mr. HENRY SPADACCINI.

Inspector to the Port of London Sanitary Authority.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Was formerly a mate in the General Steam Navigation Company's ships, and has been at sea over 15 years sailing from London, when he had a good opportunity of observing the state of the river, 5266–71. During the last ten years has noticed the river to be in a very foul state, and has heard many remarks passed on it by passengers in the ships he was in, 5273–4. On the 28th July to the 29th July he took 24 samples from the river at Barking, one every hour from noon on the 28th to 11 a.m. on the 29th July, 5275–6. High water at Barking was about noon. The position he took was right in the

## Mr. HENRY SPADACCINI—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

flow of the sewage, 5277–81. The first sample was taken on the first of the ebb when the sewage was running out strongly. A barque moored off the outfall did not swing to the ebb until the sewage had been running for a quarter of an hour. The sewage began to run out before 12 noon. The smell was so bad he had to remove his boat to some distance. It made him feel sick. Could tell when the sewage began to run out by the difference in the water and by the smell. The water becomes quite blue-black in colour, 5282–94, 5296–7. At three o'clock the sewage was running out so slowly as not to be perceptible on the surface as the sewage runs out under water. The arches were beginning to be uncovered, 5295, 5298, 5299. At four o'clock the arches were uncovered three feet, and the sewage was running out at the rate of one knot per hour. The sewage at this time was "pure, undiluted" sewage. The boat was on the sill, and the sample was taken from the sewage as it poured out, 5300–4. At five o'clock there were seven inches of sewage on the sill which was between 65 and 70 feet wide, 5305–6. At six o'clock there were five inches of sewage flowing from arches Nos. 1, 2, 8, and 9, at the rate of one knot per hour, and from the other five arches at half a knot per hour, 5307. At 6.45 p.m. the barque swung to the flood tide, 5308–9. At 8 p.m. he noticed large patches of sewage deposit become detached from the river bank and float up the river with the flood tide, 5311–2. At 9 p.m. he noticed a strong sewage smell, but is unable to say whether the sewage was still being discharged, 5313–4. Past midnight, at nearly high water, there was no doubt that the sewage was being discharged, both from the smell, and also from the ripple on the surface of the water, and that it was running up the river, judging from the position of the barque as she swung at her moorings, 5315–8. At 7 a.m. the barges in the offing swung athwart the river, there being no tide there at dead low water. Sewage was running out over the sill at the rate of one knot per hour, 5319–22. There was no rain at all on this day during the whole time he was taking samples. There was a slight fog at night, 5323–5. The samples he took were handed over to the Port Sanitary Authority at the office in Greenwich, and were the first he ever took. Has taken samples since, records of which can be produced if necessary. The arches are covered as early as the second hour of the flood, as the tide rises very quickly, 5334–48. The barges swung to the flood at 7.35 at which time the sewage was running out over the sill at the rate of one knot per hour, 5349–50. Hands in notes of his samples, 5276.

Discharge of Sewage from the Main Outfalls at Improper Times.—At 7 p.m. the sewage was flowing from the end arches and mixing with the water of the flood-tide, and all the time he saw the sewage coming out he heard a noise in the arches which continued after he ceased to see the sewage flow. From this he inferred that the sewage was still flowing, 5019. The sewage began to be discharged on both occasions during the 24 hours he was stationed at the outfall before the tide began to go down, and naturally the sewage flowed up with the stream, 5329–32, 5315–18.

## Captain RICHARD MARSDEN.

Harbour Master for the District of Gravesend.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been harbour master at Gravesend for one year, and prior to that he had the Limehouse district, when he was able to make some notes and observations on the state of the river, which he now hands in, 3551–6. In 1879, when passing the southern outfall, he found the water very filthy, with a horrible smell. In 1880 (February) the water was very bad, accompanied by a most offensive and sickening smell. On the 24th July 1880, at three-quarters flood, the water was very foul off Cubitt Town, the stench and state of the river being very bad, with a black slimy appearance on the water. He never saw the river in a worse state than this, 5377–84. On 1st September 1880, at a quarter ebb, off the northern outfall, the water all the way down Barking Reach was in a very bad, black state, and stinking horribly. On the 2nd September he again observed a very foul stinking fluid coming out of the same outfall. On the 8th the

## Captain RICHARD MARSDEN—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

river was very bad in Halfway Reach right up to Blackwall, the water being black, and the smell sickening. Two days later the water was bad down to Erith, 5386–90. On the 29th September the river was charged with sewage, the worst coming from the northern outfall, 5391. On the 2nd September 1881 the water was much discoloured at the sewage outlets, and on the 5th September the water was very foul and stinking from the northern outfall down to Erith. Has seen the water much cleaner at times when the sewage is being discharged than at others, 5395–401.

Offensive Odours.—On each occasion when he has found the water in a foul state it has been accompanied by a most offensive sickening smell, 5380–97. The smell noticeable at Blackwall and Erith is the same as is to be found at the outfalls, only fainter, 5414.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The fishermen and others whose daily occupation is on the river are, as a rule, a pretty healthy set of men, and are not affected by any disease or illness consequent on their working so much on the water, 5410–13. Knows of none of the men in his employ who have had to give up their work on account of sickness, 5415–17.

Discharge from the Storm Overflow Outlets.—On the 24th June 1879 he noticed a large quantity of sewage coming into the river from the Ratcliff Cross outfall on the ebb-tide. Has frequently seen a similar discharge whenever there has been rain. The size of the outlet is 4 feet broad by 2 feet deep, 5357–60. On the 26th June, at 11.30 a.m., on three-quarter ebb-tide, he encountered a great quantity of sewage matter of the worst possible kind issuing from the Ratcliff Cross outlet, and he reported the fact to the Thames Conservancy Board. It could not have been worse if he had been in the sewer itself. Being just before low water the excrement would be carried up by the flood-tide and deposited in the higher reaches of the river. There had been some rain on that day, but not heavy rain. The sanitary inspector was on the river at the time and took samples, 5361–75. On the 26th October a large quantity of sewage was discharged from the same outlet on half ebb-tide, It was rainy weather on that occasion, 5392–402.

Injury to Fish.—Fishermen used to trawl for shrimps in Long Reach, and in Erith Rands good fish used to be caught, but now the bottom is so muddy, and the water so foul, nothing is found there. The eel scoots cannot lie in the river above Hole Haven, and when they are towed up to London the valves in the boats are shut to prevent the impure water getting to the fish. The shrimping boats are now fitted with boilers to boil the shrimps on board, as they are not able to bring them up to Gravesend alive in the wells of the boats, 5356.

## Mr. GEORGE ROBERT SHOWELL.

Master of the Steam Launch "Hygeia," belonging to the Port of London Sanitary Authority.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Was born and brought up alongside of the river, and has been on it for 27 years, 5418–22. Has often noticed a foulness in the condition of the river, which is worst at low water round the bight of East Greenwich. It is what he would term sewage. Has seen it at Woolwich on low water, on the young flood, and especially on high water, and all round that neighbourhood, 5423–31. Has seen the sewage stop in Halfway Reach and hang on to the eddy at the points, 5432. Has anchored frequently off the outfalls and seen the sewage discharged. It is noticeable by the colour of the water. At times, with an easterly wind, or in calm weather, it has not flowed away, 5433–8. When he has hauled in his anchor it has been covered with sewage, and the chain has had to be washed by the sailors as it came through the hawse-hole, 5457–9. The east wind and eddy tides combined have stopped the sewage from flowing away. They stop the tide also, 5460–2. Has seen the sewage at East Greenwich several times this summer on low water, 5463–8. Has had unpleasant tastes and smells from the spray of the water when he has been coming through Halfway Reach head to wind, 5477–81.

## Mr. GEORGE ROBERT SHOWELL—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Formerly there used to be 14 feet of water above the Powder House by Crossness, but now it is all mud intermixed with sewage, of a bluishblack colour, and smells badly. Has seen vessels aground there, 5450–6.

Injury to Fish.—Twenty years ago the condition of the water at East Greenwich was very good, and all sorts of fish were to be had there, amongst them fresh-water haddocks, 5470–2.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Is a good deal on the water, and has been all his life, and, generally speaking, he enjoys very good health. Has never experienced sickness or faintness from the condition of the river, 5473–8.

Discharge of Sewage from the Main Outfalls at Improper Times.—Has seen the sewage discharged two hours before high water, and continuing until three-quarters ebb. On the 16th November 1882, when with Dr. Collingridge, at 12.15 p.m., the sewage was running fast out of four pipes at Barking. It was high water at London Bridge about 5 p.m., and the tide was flowing up then, 5437-49.

## Captain JOHN FITZGERALD, R.N.

Harbour Master of the Central Station on the River Thames.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is a Staff Commander in the Navy, and his district as Harbour Master extends from Greenwich to Greenhithe. Has held his position for five years, and has had almost daily opportunities of observing the river, 5482–6. There has been a change for the worse during that time, especially in 1880 and 1881. The water has become very much worse, and it is, in his opinion, due to the outfalls at Barking and Crossness. At present it is comparatively clear, 5487–91. Has kept a journal daily, and entered in it particulars as to the state of the river. In 1880 he took special observation, as it was in a worse state than it had been before. He also took special notes in 1881, 5492–6. On the 24th June 1880 the stream on the flood and ebb was apparently charged with sewage, and the smell from the river most offensive. On the next day, between Charlton and Erith, the smell from the sewage pervaded the river, being quite as strong on the flood as on the ebb. On the 26th June the smell was still offensive, though not so bad. On the 6th and 7th July the smell was very bad in Erith and Halfway Reaches, the water being comparatively clear on the 6th, but much discoloured on the 7th. On the 9th the water was much discoloured, and smelt badly all over his district. On the 11th the water above Woolwich was strongly impregnated with sewage, 5498–5509. On the 12th July he landed at the southern outfall at half-flood to complain of the state of the river, and was told the sluices had only been opened at the proper time. But as the upper part of the river was foul, and below the outfalls it was clear, he doubted the statement, 5510–1. The same condition existed until the 17th July, when the river was in a worse condition than he had ever known it from Woolwich to Erith. From side to side it was heavily charged with sewage, and the stench almost unbearable. On the 18th it was black with sewage, but it got clearer next day on the surface, but bad inshore. On the 21st the surface was clear, but filthy and stinking underneath; the steamers passing stirred it up, and at Leatherbottle Point the water was nearly black at the last quarter flood for a mile, 5512-21. On the 22nd July the river was in a filthy condition from Charlton to Erith, and the sewage was apparently working its way up. He could see it. It continued in this state, and on the 26th July at low water the river was choke full of sewage from "Bugsby" down. Stench abominable. Same on the flood. As the tide fell the water got "thicker," or had more suspended matter in it. On the 27th the water was tolerably clear at high water, but big black patches varying in size were visible at first quarter ebb. He fancied these patches were due to the clean water being swept away from the surface, 5522–36. His opinion is that these patches were sewage, 5537–9. From the 28th July the river got clearer in places, and the smell gradually diminished (but the foreshore and landing-places were clothed with sewage mud) until the 5th August, when it was fairly clean and free from smell, and, with a few exceptions when the foul state

## Captain JOHN FITZGERALD, R.N.—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

and smell were noticed, it continued to remain clean. At the end of August he went on leave, and the observations were continued by the officer who relieved him. The cause of his taking all these observations was simply the excessively foul state of the river, and he felt it to be his duty to notice it, and report the facts to the Conservators. The weather was hot and sultry, 5556–7. In October he noted that the river was charged heavily with sewage, especially in Erith and Halfway Reaches, and air bubbles were visible right across the river, 5558. From October to the following July the river was not so bad as it was in the summer owing to the cool weather, and the fresh water coming down, 5562–5. In July and August 1881 the river became very foul and offensive; it was nearly as bad as in 1880. He took notes of the state of the water, which correspond almost entirely with those taken in 1880. The weather was hot, 5559–61, 5556–85. On the 19th August, at 2¾ hours before high water (at 6.40 p.m.), the northern outfall was flowing into the river, and a sample was taken by two of his watermen. High water was at 9.25 p.m. on that day, 5586–8. In 1882 he took some notes of the state of the river. On the 17th March, at the last quarter ebb, the river in Halfway Reach and off Erith was in a very foul state and smelling badly. On the 30th June the water off Charlton was very offensive, and smelt strongly of sewage at two hours flood; on the 10th August the water at last quarter ebb in Halfway Reach was very turbid and full of air bubbles, giving off offensive odours; and on the 28th August the river in Halfway Reach, and off Erith, was very much discoloured and smelt badly, 5598–5604. During September he was away on leave, but on the 26th October the water in Barking Reach was heavily charged with sewage and smelling badly, 5604–5. He began to take notes of the river in 1878, but confined them principally to the summer months. The river has not been so foul in 1882 as in former years, which is due to westerly and south-westerly winds accompanied by a good deal of rain. The foulness is due to the discharge of sewage from Barking and Crossness outfalls, 5606–12. Believes he commenced making entries in his journal in 1877, soon after he took up his duties as harbour master. Quotes extracts from his journal of December 1878 up to June 1880 as to the state of the river, which he made on board the "Conservator" at her moorings off Charlton, 5638–50. There are very few entries as to the clear state of the river, owing to its seldom being in a state to justify him calling it so, 5651–5. The expression "charged with sewage" which he has frequently made use of means that the water was full of sewage from its containing a lot of suspended matter in it, 5656–7. The cause of his watching the outfalls in 1881 was to ascertain the reason why the river was in such a filthy state. During the night tides he sent two men to watch, and he went in the daytime, 5663–4. At times the water would be clear on the surface, but directly a steamer passed the screw would stir up the lower part, and it would be found to be in a filthy stinking condition. He has seen this in all parts of the river, except in Long Reach, within his district, 5665–71. The sewage during the worst part of the seasons of 1880 and 1881 filled the river, and gradually extended upwards as the seasons advanced until it reached Greenwich. Now it is very much better than it was three years ago, 5672–7. Speaking generally, there is nothing offensive in the river at present, but it has been very bad this year (1882) on days when he has not recorded the fact, 5678–81. Has steamed and rowed through the black patches on the river, but has never examined or analysed them. Has taken the temperature of the clear water and of the sewage, and has found that there is a difference of eight or nine degrees between them. He recorded those observations, 5682–9. The samples taken at the outfalls in 1881 were handed over to the Conservators for analysis. The men reported verbally to him the state of the river, &c., although they made notes at the time, 5690–6. The patches on the river were from the smell composed of sewage, 5697–9.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—In 1878, on the 18th December, he personally took observations on the depth of the mud at various places in the river between Woolwich and Erith. The depth ranged from 5 feet to 15 feet. (*The paper containing the details was handed in, and will be found*

## Captain JOHN FITZGERALD, R.N.—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

*after Q.* 5615 *in the printed evidence.*) On the 20th November 1882 the steamship "Fatfield" was in collision, and was run ashore in Barking Reach on the Essex side above the "Farmer's teeth" and embedded herself in 12 feet of mud, 5615, 5623-5. He saw the ship in the mud, which was black stinking sewage mud, 5625-6. The conclusion he drew from these observations was that the mud was increasing in the river, 5616-7. His opinion was that the mud was composed mostly of sewage. (*This was objected to by Mr. Bidder, as no analysis was made by witness.*) He is familiar with Thames mud. The mud he sounded varied in character. In some places it was black stinking mud, and not so bad in others. Samples were taken at these places from time to time, and were analysed by competent men, 5622. The observations handed in were taken in 1878 for the purpose of the Mud Inquiry, at which he gave evidence. The cause of the mud banks he takes for granted in consequence of what he sees, 5627-37. In going up and down the river he has probed the depth of the mud at different places in addition to the observations taken in 1878, and although he has not recorded the results he has formed in his mind an opinion as to the state and condition of his district generally. His inference that the accumulations of mud were due to sewage was drawn from his subsequent observations, and not from the experiments made in December 1878. He compared the 1878 soundings and the depth of the water with the surveys taken previously, and he drew his inference from that also. The increase is going on, and he attributes it, not wholly and solely, but mostly, to the contribution of sewage, 5700-13.

Offensive Odours.—During the summer months of 1880 and 1881 the river was in a very foul state and the smell from it was abominable. The smell pervaded the air from Charlton to Erith. At times it was almost unbearable. One of his men was sick from the smell. The smell was very bad for 23 days in 1880, for 16 days in 1881, and on a few occasions in 1882, 5497-605. On the 10th August 1882 the smell was very unpleasant, 5658-62.

Discharge of Sewage from the Main Outfalls at improper Times.—On the 12th July 1880 he landed at the southern outfall to complain of the state of the river. He was told the sluices had been opened at the proper time, but he doubted that, as, the tide being half flood at time, the river below the outfall was comparatively clear and the air free from sewage taint, while in Barking Reach it was the reverse, 5510-1. On the 19th August 1881, at 2¾ hours before high water, sewage from the northern outfall was observed to be flowing into the river, a sample of which was obtained in front of the works by two of his watermen. High water would be above 9.25 p.m. on that evening, 5586-88. On the 20th, 21st, and 23rd August sewage was seen issuing from the northern outfall on the half flood tide by the same two men, 5589-93.

## Captain CHARLES HENRY JAMES.

Harbour Master of the Thames Conservancy at Greenwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has known the river all his life, and is now 69 years of age, 5714-6. Has been harbour master at various points of the river since 1840. For 11 years his district was from Gravesend to Woolwich. In 1850 or 1851 he came to Limehouse district, which extends from Limehouse to London Bridge, 5722-5, 5730, 5734-5. Is now harbour master at Greenwich, 5727. In 1828 he went to sea, and at that time people used to drink the Thames water and take it to sea with them. It was taken from a hulk outside the East India Docks and put in casks, 5717-21. Between 1840 and 1850 the water between Gravesend and the lower part of Woolwich was perfectly good and sweet, and could be drunk at low water, 5730-3. In 1850 a good many people used to drink the water at Limehouse, but shortly after 1851 people ceased to drink it, 5736-8. The outfalls were opened from 1863 to 1866, and since then the river has become very foul from London Bridge downwards, and that is proved by the eel-schuyts being driven down to Hole Haven, 5741-4. From time to time, when the river was very bad, he has made entries in his journal, and reported the fact to the Conservators, 5746-9. In the year 1880, he was ordered by Captain Burstall to make entries as to the

## Captain CHARLES HENRY JAMES—*continued.*

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

state of the water, 5750-3. From the 29th to the 31st July he found the river between London Bridge and Greenwich very black and offensive, and on the last day Deptford Creek as well as the river were alike black and offensive, 5754-60. From the 1st to the 15th August the river was very foul and offensive, and on the 16th August it was rather improved in character, 5761-76. Then from the 17th August to the 14th September the river continued in the same foul and offensive state. Then on the 15th September it improved somewhat, but got worse again until the 21st September, when his entries end for that year, 5777-82. In 1881, from the 5th July to 4th August, the state of the river was much the same as in 1880, very foul and offensive, and improving occasionally for a day or two, and then reverting to its foul condition, 5783-800. When the river water was taken to sea it always fermented or putrefied, and the bungs had to be left out of the casks to allow the gases to escape. They would ignite otherwise if a light was applied to them, 5811-2. The general tone of the water is better than it was before the outfalls were opened, and the water is sweeter from London Bridge to Limehouse, but its condition is worse than it was in 1854. The lower reaches of the river have become fouler year by year, 5813-8. If any offensive matter comes to his district from Barking and Crossness it must traverse Captain Fitzgerald's district. His statements respecting the condition of the river are correct, so far as his district is concerned, and the difference between his entries and those of Captain Fitzgerald's entries for the same periods would be accounted for by the districts being different, 5823-35 The removal of the sewer outfalls to their present position has improved the upper parts of the river, except in very hot and dry weather, when they are just as bad as the lower parts, 5842, 5844-46.

Offensive Odours.—During the summer months of 1880 and 1881 the river was in a very foul and offensive condition, and has found a very disagreeable smell arising from it. He lives at Greenwich close to the river, and is in the habit of sleeping with his window open from May till October, but he has frequently been obliged to get up and shut it in consequence of the smell. Frequently, going up and down the river, it has made him quite ill, and he has not been able to eat his dinner when he got home, 5754-807.

Popular Evidence as to the Deposit and Accumulation of foul mud near the Main Outfalls.—Gave evidence at the "Mud Inquiry" as to the accumulation of mud banks in the Thames, which he is certain are caused by sewage. He always predicted that the outfalls would cause these deposits, as they have done, 5819-20.

Injury to Fish.—Whitebait used to be caught in the Thames at the entrance to the East India Docks, at Blackwall, but there is none to be met with in the river now, 5739-40. The eel-schuyts were driven away from Erith in 1869 to Greenhithe; then they went to Gravesend in 1870, and after two years they left for Hole Haven, where they now lie, 5744-5. Is perfectly sure that he is correct in his dates, though others may have fixed an earlier time for the departure of the eel-boats from Erith. The last did not leave till 1869. Whitebait are caught now in the Medway, 5837-41. Whitebait were not caught at Blackwall after 1851, but were caught later in Long Reach, 5843.

## Mr. WILLIAM COLLINGRIDGE, M.A., M.D., M.R.C.S., S. Sc. Cert., Camb.

Medical Officer of Health to the Port of London Sanitary Authority.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Was appointed officer of health in May 1880, as successor to Dr. Harry Leach, who died, 5847-9. Has spent a great deal of his time on the river since his appointment, principally between Westminster and Purfleet, 5850-4. During the last two years, in the summer months particularly, the river water has been extremely bad. After two or three hot days the water becomes darker, he notices black patches of sewage on the river, and there is a very offensive smell. The patches are worse in the neighbourhood of the outfalls and above, not so much below. The state of the river is foul, 5855-8, 5861-2. Any agitation in the water, such as a steamer passing through it, exaggerates the condition of the river. Has noticed

MR. WILLIAM COLLINGRIDGE—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

the water clear on the surface and foul below, and smells arise when the water is disturbed, which are not noticed at other times, 5859–60. The patches are caused by the influence of the tide or some other influence bringing up the sewage from the bottom of the river. He has taken samples of them and examined them, but not chemically. They are very thick indeed; there is a large amount of suspended matter, and the smell is horrible. He would describe them as slightly diluted sewage, 5863–6. He has frequently watched the discharge from the outfalls, and at times it can be traced for a considerable distance. (It depends very much, however, on the state of the weather and the wind.) It is a very dark smooth stream, which can be seen distinctly running side by side, as it were, with the river, which is of a brown colour. It is also distinguishable as being sewage by the small pieces of fæcal matter (sometimes in large masses), matches, corks, paper, and vegetable matter. He has traced it from Crossness to Erith. If there is any wind the surface of the river is rippled, but the sewage stream is perfectly smooth from the oily or greasy matter in the sewage, 5867–77. The last years have been exceptional years as regards the state of the river. In July 1880 it was worse than he ever saw it, though it was very bad in June 1882, when the weather was very hot. There has been very little hot summer weather during the last three years, 5899–902. In July 1880 the river was worst at the outfalls, after that it was worst at Woolwich and Jenningtree Point, and he reported the condition of the river to the Conservators, 5903–7. In 1881 the river was in much the same condition as it was in previous years, though not quite so bad as in 1880, because the hot weather did not last so long. He again called the Conservators' attention to the river, and urged the Port Sanitary Committee to take some steps in the matter; the result was that an application was made to Government, 5908–13. Hands in extracts from his reports to the Port Sanitary Committee for the half-years ending 31st December 1880, 30th June 1881, 31st December 1881, and also from a report presented on the 5th October 1882 on the state of the river. These extracts are identical with the evidence given by him on this subject, 5928–32. On the 8th December 1881 he reported to the Port Sanitary Committee the results of an investigation of a sub-committee which had been appointed to inquire into the condition of the river. Samples of water were analysed with the object of obtaining an independent result. A table showing the amount of sewage discharged from the outfalls from 1869 to 1878, and another giving the number of foul outfalls within the jurisdiction of the sanitary authority, were included in the report. An analysis of the water, with remarks by Professor Wanklyn, was also submitted, 5928–32. The large amount of fæcal matter discharged into the river from all outfalls converts what would otherwise be a tolerably clear stream into a foul sewer, 6756–7, 6791, 6833–4, 6845–6. There were, in 1881, 181 outfalls into the river from towns on the banks between Teddington and Shadwell on the north side, and 182 on the south between Ham (Surrey) and Gravesend, 191 of which were within the jurisdiction of the Metropolitan Board of Works. Some of these have been closed, while others still exist. He has received no complaints for the last 18 months of any of these outfalls being foul, but two years ago he had a great many complaints about the outfall at the Beckton gasworks, which used to discharge a certain amount of sewage mixed with gas liquor, 6758–76. Richmond and Barnes remain in the same condition as they were in 1880. At Rotherhithe two outfalls have been closed, and the rest are very small. From Greenwich to Gravesend there is no change, 6777–82. The floating population contributes a large amount of sewage to the Thames. Dr. Leach estimated the population at from 15,000 to 20,000, but witness believes it to be too large an estimate, 6783–4. In his Report of 5th May 1881 the samples which he stated to be sewage more or less diluted were not analysed, 6785–6. He condemned 30 tons of fish which were in a craft moored off Billingsgate, which caused an intolerable stench on the river from being in an advanced state of decomposition, 6792–4. The discrepancy existing between Professor Wanklyn's analysis and his own cannot be put down to the incorrectness of his method of estimating the impurities in water, 6810. The increasing impurity of the water as it comes down the river from Teddington

MR. WILLIAM COLLINGRIDGE—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

is due to the sewage which is poured into the river on each side, 6811–12. On the 23rd November 1881 he took a sample of water 300 to 400 yards from the Barking outfall, on the edge between the line of sewage and the river water, which contained one-fifth of its volume of sewage, 6813–19. At Tilbury on that occasion all trace of sewage in the water had disappeared, 6820. The upper part of the river has decidedly improved since the removal of the sewage to Barking and Crossness, 6821–5. In Limehouse Creek a nuisance was caused in 1881 by an accumulation of floating vegetable matter and a discharge from two closets. The creek was cleaned out and the closets were abolished, 6826–7. Where an outfall exists which discharges at a point below low-water mark, and it also discharges at low water, there is always some amount of nuisance, which he has noticed in certain cases, 6830–1. Of the outfalls he mentioned (*Q.* 6758, *et seq.*), by far the greater number are very small indeed, a single drain or closet. The large outfalls are very few in number, and they are at Richmond, Bow Creek, West Ham, North Woolwich, Beckton, and the West Kent outfall. Barnes has a number of small outfalls, 6835–41. The "Cornwall" is moored in a very unfortunate position, as it is a point where the sewage is carried directly round the vessel. She lies off Purfleet in a bight, 6851–2. The sewage discharged from the small outfalls bears an infinitesimal proportion to the discharge from the main outfalls, 6862–3. In no case except at Southend did the taking of the samples occupy more than a quarter of an hour. Three samples were taken at Gravesend, but he was not present. He is able to tell the time occupied by the labels on the bottles which give the actual time each sample was taken. There was only one boat manned by two men who only had to row half across the river. Six specimens were taken, three at the surface, and three at 20 feet below the surface, 11,752–7.

OFFENSIVE ODOURS.—During the last two years the river, from its exceedingly foul state, has been very offensive, and when the water is clear on the surface the foul matter below, when disturbed by the passing of a steamer, or from any other cause, causes a very bad smell to rise. He has taken samples of the black patches which rise to the surface, and the smell is horrible, 5855–65. The smells from the factories are quite distinct from the smell of the river, and with the wind blowing across the river it is quite possible to check off the factories as you come to them, 5921–3.

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—The mud on the banks is a dark slimy black stuff, and has a peculiar gelatinous appearance, which is particularly noticeable near the outfalls, 5918–20.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—In his opinion it is impossible to pour sewage into the river to the extent it is done without serious danger to health, 5914. In hot weather he has frequently suffered inconvenience from the state of the river. It has caused distinct nausea, and in several cases actual vomiting. It has also produced diarrhœa. These symptoms are undoubtedly due to the river, for he only has them when his duty keeps him on the river for any length of time, and they disappear after he has stayed on shore for three or four days, 5915–7. Hands in extracts from his Report to the Port Sanitary Authority for the half year ending 30th June 1880, on an outbreak of typhoid fever on the steamship "Condor," which was due to bad water, and also on the health of the school ships stationed in the river, and the outbreaks of fever, &c. thereon. Extracts also were handed in from his reports for the half years ending 31st December 1880, 30th June 1881, and 31st December 1881, on the health of the training ships, 5928–32. The health of the boys on the training ships for the half-year ending 30th June 1880 was good, except a slight outbreak of scarlet fever on the "Shaftesbury" and a few isolated cases of typhoid fever on the "Arethusa." This ship appeared more liable to disease than the "Chichester," which is moored close to her, 6738–46. An outbreak of enteric fever broke out in March 1880 on the "Cornwall," into the causes of which the Local Government Board made an inquiry, the result being that it was traced to trichinosis, 6747–9. Later on in the year typhoid fever broke out in the "Arethusa" and "Cornwall," which were due in the former to the insanitary condition of the ship, and in

## Mr. WILLIAM COLLINGRIDGE—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

the latter to her position in the river and the possibility of the germs of the disease having been brought down from London by the sewers. The small-pox ship has now been moved about a quarter of a mile below the "Cornwall," but on the opposite shore, 6796–6806. Since the beginning of 1881 the health of the boys has been very good, 6807–9, 6828. The health of the crews of vessels frequenting the port is fairly good, though they complain of the river when passing the outfalls, 6829. Apart from the sewage, the isolated condition of boys on a training ship is favourable to health, so far as infectious diseases are concerned, 6854–6. There can be no question that such a large amount of sewage poured into the river must produce evil effects on the health of those people who live on the water or are constantly on the shores, 6857.

Discharge of Sewage from the Main Outfalls at improper Times.—Has on several occasions watched the outfalls when the sewage was being discharged on the 30th June 1882. The sewage was discharged at 7.15 p.m., just before the flood tide, 5878–83. He has seen this on several other occasions, but can only give the dates of a few occasions. It is by no means rare to see the sewage discharged on the flood or just at low water, the effect being that the sewage is carried up the river by the flood tide. Has traced the sewage as a distinct stream as far as Blackwall. It can be traced higher up, though not so distinctly, 5884–98. It is not the fact that he had the outfalls watched for a considerable time, and that there was no discharge on the flood. They were watched for a week once in 1880, as he stated in his report for July 1880, when no discharge took place on the flood, and he said so in his previous evidence, 6733–7, 6750–5, 6787–90.

Population of Towns draining into the Thames.—In the case of the upper part of the river he is unable to state the population of the towns which drain into the river by small outlets. At Richmond cesspools exist to a large extent, 6842–4, 6863–4.

## Mr. THOMAS LONG.

Waterman in the employ of the Thames Conservancy, on board the "Conservator."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—Has been on the Thames nearly all his life, and for the last three and a half years has been in his present situation. Before that he was working on barges doing lightering, 6042–6. In July 1880 the river was in a worse condition than he ever knew it. Lumps of stuff used to rise from the bed of the river to the surface, break open and emit a fearful stench. They seemed to be "all black mud stuff," 5945–49. In August 1881 he was sent with another waterman by Captain Fitzgerald to take samples of water at both the outfalls. They went principally at the night tides, and the four samples from the southern outfall were all taken at high water and were clear. Samples were taken from the northern outfall on five nights. All the samples were taken about two hours before high water, and on three nights the sewage was discharging, and the samples were very thick and almost black. On the 21st the sample was clear. The other two nights at the southern outfalls the samples were clear, 5950–6011. These samples were handed to Captain Fitzgerald. The bottles were put just underneath the surface. At the northern outfall they were about 30 or 40 feet from the outfall, and at the southern outfalls they were over the lip of the outfall, 6013–25.

Offensive Odours.—The patches of mud which rise from the bed of the river emit a fearful stench as they break open, 5945–9. The samples taken at the northern outfall smelt badly, 6020–3. The smells from the factories are not so bad as the river smell, and do not make him sick. A load of manure on a barge does not smell so much as when you are away from it. He never experienced any unpleasantness from it, 6035–53.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has several times been affected by the smell from the river and felt excessively sick. Others have felt the same on board. Has excellent health as a rule, but the smell makes him qualmish, 5935–44. Is ten hours a day on the river on an average, but it does not always affect his health, 6032–4. In the hot weather he feels sick even as early as 4 a.m. from the river smell, 6039–41.

## Mr. THOMAS LONG—*continued.*

Discharge of Sewage from the Main Outfalls at improper Times.—On the 19th, 21st, and 23rd August 1881, in taking samples of water from the northern outfall about two hours before high water, sewage was being discharged from the outfall. He could see it coming out through the sluices, and it washed the boat away from the sluices, 5987–6008, 6054–5. He was only about 30 or 40 feet from the outfall, and the samples he took were absolutely sewage, 6020–31. The sluices were not covered as the foreman of the works came out on the top of them to speak to witness, and at that time the sewage was flowing into the river. The arches were not covered at two hours before high water, but would be at three parts flood, 6056–63.

## Mr. GEORGE LAMERTON.

Waterman on board the "Conservator."

Discharge of Sewage from the Main Outfalls at improper Times.—He accompanied Long when they took samples from the outfalls. On the 19th August he saw the foreman of the works come out on to the top of the arches at the northern outfall, and he also saw the sewage flowing into the river. The arches would be covered about half flood, but when the samples were taken the water came half-way up the arches. The discharge washed the boat away from the sluices, 6064–75.

Offensive Odours.—The smells from the river have made him feel very queer, and they are much worse than the smells from the factories, 6080–4.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has been on the river for 17 years, and has spent his whole time on it for 12 years. Is on the river now for 10 or 12 hours a day, or sometimes all night. Has never been laid up from the smells from the water, but it has made him very queer. The smells from the factories are not pleasant, but they never make him sick, though you could not stand the smell for a long time. Is 28 years old, 6076–84.

## Mr. WILLIAM TURNIDGE.

Waterman on the Steamer "Conservator."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been waterman on the "Conservator" for four years, and his duty keeps him on board at night sometimes. The steamer is moored at night off Charlton, and he has found the river very offensive at times, but it was at its worse state in July 1880, when the weather was so hot, 6085–95, 6103–5. Was a fisherman before he entered the service of the Conservancy, and has also been to sea. Is from 10 hours upwards on the river daily. His age is 32 years, 6106–12.

Offensive Odours.—On the 26th July the smell from the river was so bad that it made him sick, and he was obliged to leave his work. He felt very unwell for several days after. The smells have affected him on other occasions. The odours from the factories are not so strong as the river smell, nor has he ever felt any ill-effects from them, 6113–17, 6120*a*–5.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The smell from the river has on several occasions affected his health, and once he had to leave his duty and lie up. He was unwell for several days. There was nothing but this sewage smell to account for his sickness, as he generally has very good health. It was 3 o'clock in the morning when he was taken ill, having been on watch all the night, 6095–6101, 6106, 6120*a*–25.

## Mr. GEORGE YOUNG.

Master of the Steamer "Conservator."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been master of the "Conservator" for two years, and in the service of the Conservancy for 18 years. Prior to that he was a collier's pilot, and has known the river for 30 years, 6126–32, 6290. Before these outfalls were opened the river from London to Bugsby and Woolwich was very bad indeed; but in Gallion's Reach colliers used to draw their water for drinking purposes at low water up to 1864. In Barking and Half-way Reaches the water was brackish, through comparatively clear. Since the opening of the outfalls there have been very great

MR. GEORGE YOUNG—*continued.*

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

changes in the river. It is now a mass of sewage, which works it way up as far as Greenwich. His ship is moored at Charlton, 6133–46, 6285–87, 6291–300. In 1880 he took notes on the state of the river when it was very bad indeed. The sewage turned the paint and the composition on the bottom of the steamer quite brown, and she had to be taken to the blocks at Greenwich to be cleaned on the 26th July. The composition had only been put on three weeks before, and was quite clean a few days prior to the 26th July, 6163–75, 6250–56, 6267–72. At this time the water was so filthy that it could not be used for washing the decks or cabins, and the same state of things existed in September, 6176–83, 6243–47, 6273–76. No samples were taken at this time nor in 1881 or 1882. Samples taken for the purposes of the Sewage Inquiry were taken when he was absent on leave in August 1881, 6273–78. If the water is in a fit condition the decks are washed daily, 6288–9. The river at Charlton and Blackwall has become filthy since the opening of the outfalls, but is not so bad at Blackwall. It gradually improves as you go higher up, 6303–7. In July 1881 the river was so full of sewage that they were unable to use the water to clean the decks, and on the 18th July they were compelled to wash the decks down at Greenhithe. On the 20th July and following days they were obliged to obtain clean water from the shore for cleansing purposes, 6184–202, 6205–7, 6279–80. On the 21st July the river was in a filthy state of sewage, more especially between Barking and Jenningtree Point, 6203–4. It was excessively filthy on the 2nd August at Charlton, and the decks were washed in St. Clement's Reach. From Barking to Rainham on the 5th September it was just as bad, 6208–11. In March and April 1882 the river was in a very filthy state, and again in June, July, and October. The stink was most offensive. In March they were unable to wash the decks for a week. The sewage can be seen coming out of the outfalls, and makes a distinct track on the river. In October 1882 the bed of the river appeared to be in a state of fermentation, as patches rose to the surface and burst, throwing off a most offensive smell, 6212–29. Has been engaged for the last twelve months in taking people up and down the river on account of the Sewage Inquiry, and taking samples, 6234–8, 6279. The year 1880 was the worst, and then 1881. This year the river has not been so bad as the two preceding years, 6239–42. In 1881 the "Conservator" was undergoing repairs until the 12th July, 6248–9, 6308. On the 23rd July 1881 the water appeared to be clear on the surface, but on dipping a bucket into it 12 inches below the surface the sewage was found to be there, 6207, 6282–4.

OFFENSIVE ODOURS.—In 1880, 1881, and 1882 the river, during the summer months especially, was in a filthy state, and full of sewage. The stench from it was very bad between Charlton and Erith, 6167–229.

INJURY TO FISH.—No great change took place in the places where fish used to be caught until four or five years after the outfalls were opened. Greenwich Bight, Bugsby, North Gallions, Long Reach, &c. were the principal fishing grounds, 6148–51. Now no fishing goes on in these Reaches, 6152. Quite recently some fish brought down by the heavy rains have been caught on the shore at Charlton by children with their hands. The fish seemed to become sickly and weakened as soon as they came into contact with the polluted water, 6153–62.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—On the 26th July 1880 one of his men, Turnidge, was taken ill from the effects of the foul state of the river, and he had to leave his work of cleaning the bottom of the steamer. All on the boat, including himself, were feeling "queer" that morning, but were not incapacitated for work except Turnidge, 6251–5, 6268–71. Twenty years ago, when the upper part of the river was so foul, he had an attack of cholera owing to its condition, 6298.

MR. JOHN PHILLIPS, Putney.

Formerly Chief Surveyor to the Metropolitan Commissioners of Sewers.

METROPOLITAN MAIN DRAINAGE, PAST AND PRESENT.—In 1847 he was appointed Chief Surveyor to the Metropolitan Commissioners of Sewers, who had the entire management of the sewers of the Metropolis until they passed into the control of the Metropolitan Board of Works in 1855, 6313–6. He had considerable practical experience in work of this nature, 6317–8. In 1847 he made experiments in the Westminster sewers and ascertained that sewage must flow with not less velocity than 2½ feet a second both in the large and branch sewers in order to prevent fæcal and other matter in suspension from depositing, 6319–21, 6387–90. There are hundreds of miles of sewers in London now where the velocity is less than 2½ feet a second. These are called "deposit" sewers. They have nearly flat bottoms, with upright sides and arched tops. To concentrate the flow and maintain the velocity, the sewer should be shaped like the letter V, 6322–6. The sewage at this time was discharged into the Thames, and the outlets were considerably above the low-water level. Old London Bridge dammed up the water, and the level at low water was four or five feet higher above the bridge than below it. The removal of the bridge brought the water to the same level, and enabled the flat marshy districts above Westminster to be drained lower than before, 6327–31. Wooden trunks had then to be fitted to the outfalls extending down to low water, to prevent the sewage spreading over the banks; but it had very little effect, as the flood-tide brought the sewage back again, making the banks as bad as they were before, 6334–8. In 1846, in conjunction with Mr. G. Hawkins, they ascertained from gauging and other experiments that 1,798,094 cubic feet of sewage were discharged into the Thames at Westminster daily, which corresponded pretty accurately with the daily water supply to the houses, 6339–42. Each house had from one to three cesspools, communicating with the sewers by an overflow pipe. In 1848 they began to abolish cesspools and substituted waterclosets, 6343–5. He calculated that the capacity of these cesspools was equal to a canal 20 feet wide, 5 feet deep, and 10 miles long. Sewage enough to fill this hypothetical canal was therefore poured into the Thames, 6346–51. In 1849 there was a serious epidemic of cholera, and it was considered preferable to allow the sewage to be discharged into the river than to detain it in the cesspools, and decompose there. The river in consequence became so foul that it caused an outcry, which led him to consider the question of preparing a system by which the sewage not only of London, but of all the towns in the Thames Valley from Windsor, might be carried off, 6352–6. Mr. F. Forster was appointed engineer to the Commissioners, and he was directed to prepare a scheme for the disposal of the sewage by means of outfalls, which was submitted to the Commissioners in 1850, 6357–65. Has frequently removed the "deposits" from the sewers and found them to consist chiefly of night-soil, and house and street refuse matter, which form the compound known as sewage, 6383–6, 6388–9.

SET OF THE TIDE.—In 1851 the engineer to the Commissioners of Metropolitan Sewers directed him, in conjunction with Mr. Betts, to make a series of tidal experiments after the sites for the outfalls had been fixed. They were made by means of a wooden float, six feet long, and extended over various days. He followed the float himself in a boat, and reported the result to the Commissioners on the 8th July 1851. (The particulars are given in that report, which is printed in the evidence, *see* 11th day), 6366–76. On the 11th September 1851 he reported the result of a further series of experiments, which is also given in the evidence, 6377–80. All these experiments were made during the summer, which was fine and dry, 6381–2. The float was always kept in the full strength of the tide, and when it showed a tendency to get into slack water it was hauled out into the stream. The results show, therefore, the greatest velocity, and not the average velocity, of the tide, 6391–3.

POPULAR EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—When old London Bridge was removed, the water which had been dammed up by the pier fell from four to five feet to the level of the water below the bridge, and consequently exposed more of the river banks than formerly. The sewage discharged from the sewers spread all over the banks and caused a deposit of sewage mud, which increased until the surface became covered with myriads of small red

## Mr. JOHN PHILLIPS—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

worms. Wooden trunks fitted to the outfalls to carry the sewage down to low water had little or no effect, for the flood tides brought the sewage back again and spread it all over the banks, which became as bad as before, 6331–8.

## Captain EDWARD BURSTAL, R.N.

Secretary to the Thames Conservancy Board.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—Has known the river since 1832, and was employed in that year under Captain Bullock in surveying the river for the Admiralty. In 1861 the Conservators ordered a survey to be made on the same scale, and on comparing the two charts he found very little difference between them, 6394–6402. Between these two years a great many hand-dredgers were at work, and the spits at Leather Bottle Point and Jenningtree Point, both in Half-way Reach and on the south side of the river, were dredged away. This would have the tendency to conduct the stream more to the middle or south side of the river, both on the flood and ebb tides, 6403–7. The Dagenham shoals and other banks were also removed, 6408–10. Rand's Hill has been removed since 1861, as it appears on the chart, 6411–13. There is a quantity of mud deposited on the south shore between Margaretness and Leather Bottle Point, and on the north shore below False Point. It has accumulated since the outfalls were opened, and is composed of very black mud, very deep and very slimy, and not much sand or gravel. It is totally different to mud found in other parts of the river, and smells badly in warm weather, but not in cold weather Has found no smell in mud taken from the middle of the river opposite the outfalls in cold weather, 6414–23, 6428–33. The bank in Barking Reach is caused, in his opinion, by the dirty muddy water being stirred up by steamers going over the shoal off the southern outfall, and it is carried up by the flood tide, and it is deposited in the slack water in Barking Reach, 6433*a*–4. Colliers drawing 16 feet of water used to come up the river and lie in Half-way Reach until their cargoes were sold. Now there is about seven or eight feet of water there, 6435–9. The fairway for many years was right down to the southward of mid-channel of Half-way Reach, 6440. About three years after the outfalls were opened the Conservators directed a new survey of the river to be made, on account of the filling up of the river, and it was compared with the chart of 1861. It was found that a large mudbank had formed off the southern outfall, and water of only 8 or 9 feet at low spring tides where formerly there were 16 feet, 6441–5. Owing to dredging in Erith Reach, shoals which were marked on the 1832 chart did not appear in 1861, and the depth of water was consequently greater. The low-water mark at Erith was also closer to the shore, 6446–9. In 1879 another survey was made, and there is a large accumulation of mud in Erith Bight all along the shore to the vertical depth of from 8 to 10 feet; the depth of water had also decreased from Erith church, past the Club causeway down to the pier, 6450–6. The mud is black and very similar to that which he described further up the river, 6457–9. A further survey was made in October 1882, which shows that the accumulation is still going on, 6460–1. In 1879, in consequence of a petition from the inhabitants of Erith, the Conservators lengthened the causeway 50 feet, as it was covered with an accumulation of mud, and the Yacht Club for the same reason have also lengthened their causeway. There are only two or three feet of water at low tide now at the warping buoy, where formerly the depth was 13 feet, 6462–76. He cannot attribute this accumulation of mud to the removal of a shoal in the middle of the river three-quarters of a mile below Erith. The water would rather be deepened thereby, 6477–84, 6528. The accumulation of mud in Erith Bight is caused by the dirty water from the sewers, 6501. He gave evidence at the Mud Inquiry, and the only banks that the Conservators elected to have dealt with by the arbitrators were those in Barking and Half-way Reaches. No mention was made of Erith in that inquiry, 6504–12. Although he has stated in his evidence that the accumulation of mud at Erith has interfered with the landing of people at the causeways, and so to a small extent with the navigation of the river, the Conservators did not think it worth while to bring up the subject at the Mud Inquiry, and he would not have referred to it to-day but for the memorial of the Erith

## Captain EDWARD BURSTAL, R.N.—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

inhabitants, 6513–6. The greater part of Rand's Hill was dredged away between 1832 and 1861, not since 1864, although part of it may have been, 6517–22, 6572. The sectional area of the river cannot have been much increased by the removal of this shoal, and he does not believe much in sectional areas, 6523–7, 6592–3, 6601. His evidence before the Rivers Pollution Commission as to the muddy state of the Thames did not refer to the neighbourhood of Erith, of that he is certain; but he has no doubt that the wash of the steamers passing up and down the river has caused a considerable degradation of the "saltings," 6530–7. The saltings are the green swards that lie between the back river walls and the foreshore. They are impregnated with salt, and cattle feed on them during neap tides, 6538–9. Screw steamers do not cause such a wash as paddle steamers, but they churn up the mud where a new shoal is forming and so create shoals on the flood, 6540–3, 6548, 6563–4, 6622–4. The condition of the river was very bad before the outfalls were opened from Greenwich to above Westminster, and there always has been a quantity of mud in it, but when he knew the river first there was very little mud floating about in it anywhere. Since the sewage was poured into it, first of all in 1845, the state of the river has been filthy, especially during 1857, 1858, and 1859, in the neighbourhood of the metropolis, 6454–7, 6549. Dredging was carried on in the various Reaches of the river between 1859 and 1879, as shown by the log-book of the late Mr. E. J. Smith, formerly commander of the "Conservator," but to what extent witness cannot say. The machines were probably bag and spoon dredgers, 6573–86, 6630–6. Referring to Q.Q. 6517–22, he has ascertained that the large middle shoal in Erith Reach was removed before 1853, and he produces a plan made by the master of the Trinity dredger "Goliath," who worked on that ground in 1853, 6593–600. Is aware that, generally speaking, other tidal rivers are quite as muddy, if not more so, than the Thames. The Medway certainly is, 6608–9. Spoon and bag dredgers are people who dredge for their own profit and sell the gravel. Steam dredgers belong to the Trinity Board. The quantity dredged by the former is small compared with the latter, and would not hold more than 40 or 50 tons. They obtain licenses from the Trinity Board, for which they pay a fee, 6637–44. A record is kept of these, which he will produce, 6645–55. *He hands in some sections of the river which have been prepared under his superintendence (see Appendices D., E.),* 6656. They relate solely to the south side of the river, and were drawn to show the deposit of mud at Erith, which has been so often referred to by witnesses from that place. He does not allow that the silting is due to the deepening of the north side, 6657–62.

Effect upon Health in the Neighbourhood of the Main Outfalls.—It is a fact that the condition of the river was such as to produce vomiting and sickness in those who worked upon the river, himself amongst the number. He had a sore mouth very often and all the mucous membrane of the lips and mouth were made bad by the offensive smell while engaged in surveying the river, 6561–2, 6629. Many men on the "Citizen" steamers, about the year 1856, were affected by the foul state of the river, and were attended by Dr. Ord, at St. Thomas's Hospital. There was not much illness amongst piermen, bargemen, and the Custom House officers at this time, 6625–9.

Injury to Fish.—About the year 1866 the fish had to a great extent disappeared from the river between London and Woolwich; and the eel-schuyts left the upper Reaches of the river before the outfalls were opened, he believes, 6565–71.

Distribution of the Sewage in the River by the various Motions of the Water.—On the 14th July 1882 he took the set of the stream by putting a float in at Barking Creek close outside of low-water mark. It drifted with a strong stream on the north shore to False Point It then gradually set off past a bay, where there is slack water and a large deposit of mud, taking a middle course down Half-way Reach. Another float put in at Leather Bottle Point, on the south shore, followed a course parallel with the south shore until it got below the outfall. The velocity of the current was 2½ miles an hour. On the north side the velocity was 2¾ miles an hour, 6427–34*a*, 6496–8, 6556–7. Hands in the results of his observations on the float experiments, 6499–500. In 1856, by order of the First Commissioner of Works, he made a series of float experiments to observe the

## Captain EDWARD BURSTAL, R.N.—*continued.*

Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

strength and direction of the tides between Putney and Woolwich, specially with reference to the new Westminster Bridge and its foundations. The result of these experiments he reported to the Commissioner of Works, and the floats travelled from 12½ to 14 miles a tide. He hands in a table containing the result of his observation of the stream (*see* Appendix C.), 6485–93. In 1856 and 1857 the sewage poured into the river oscillated backwards and forwards, passing London, as the river had not the same power to carry the sewage to the sea as at Barking, and the conclusion he came to after making his experiments was that the sewage would be carried down from Barking to the sea at the rate of five miles a fortnight; his opinion has not varied from what he stated in 1857 and 1866, 6550–4. Under the impression that the sewage would be discharged at high water when the outfalls were opened, he stated in 1866 that the sewage would be carried down to the sea and be no more seen. He thinks now it would have been better to discharge it lower down, where there is a stronger stream to carry it away, 6555–60. 6619–21. Sir J. Bazalgette took no actual part in the experiments of 1856. He simply came down to Woolwich one day for an hour, and the plan to be adopted was explained to him, but he never went on the river, 6587–91, 6602–7. In 1856 he recommended that the outfalls should be placed at Rainham Creek and Jenningtree Point, while the referees proposed that the outfalls should be below Mucking Lighthouse and below Gravesend. He thought that if the discharge began at high water the river would be safe from pollution in the neighbourhood of London, 6610–8.

## Mr. EDWIN HUGHES, Green's End, Woolwich.

Solicitor to the Woolwich Local Board of Health.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls—Is chairman of the Sanitary Committee of the Plumstead District Board, and was for 20 years a member of the Woolwich Local Board. Has lived, and carried on business, in Woolwich since 1845, and is well-acquainted with the locality and its requirements, 6663–71. Knows the river well, and has travelled on it frequently. In hot weather the condition of the river is very bad, and is getting worse. The cause is due to the discharge of the sewage at the outfalls, 6672–6. The sewage of Woolwich is taken into the metropolitan sewers, but the drainage of North Woolwich and part of East Ham is carried into a reservoir which discharges direct into the river. The Metropolitan Board contributed to the expense because they would not connect North Woolwich with their system. This discharge at North Woolwich contributes to a small extent to the pollution of the river, 6677–84. The Lea is rather worse than the Thames, and flows into the river at Blackwall, which is not in the Woolwich district, 6685–6.

Offensive Odours.—The river has a smell in hot weather, and so have the factories, but he is able to distinguish between the two, 6692–3.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls. — There is a great increase in the filth on the banks of the river from Woolwich to Erith since the opening of the outfalls; it is black now, and an artificial mud. Formerly it was brown in colour, 6687–93, 6696, 6700–4. It is impossible to land now from a boat in many places on account of these mud-banks. There are some at Woolwich Pier, but it is worse at Crossness, 6694–5, 6705–6. The accumulation has been going on gradually since 1864, at Woolwich in the bight between the dockyard and arsenal, and on the north shore between the gas works and the northern outfall, 6737–14.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The general condition of health in the district is very low. There have been 173 cases of low fever at Plumstead during the last twelve months, but the proportion of zymotic diseases is extremely low at Woolwich, 6717–23. Plumstead is more bounded by the river than Woolwich, and the cases of fever have occurred within a mile and a half from the river. Since the railway has been constructed ague has ceased because the railway cutting ventilates the marsh, 6724–7. Zymotic diseases have been prevalent on the side of the town nearest the river, which is distant about three-quarters of a mile, 6728–30. The sanitary condition and general health of Woolwich is fair, 6718–32.

## Mr. JAMES MOORE MASON, East Greenwich.

Member of the Greenwich District Board of Works.

Capacity of the Drainage System as compared with the Demands upon it; Influence of this upon the Storm Discharges.—The main outfall sewer passes from the Deptford pumping station along the Trafalgar and Woolwich Roads through Greenwich, and the whole of Greenwich is drained into it, 6865–72. For some time the system worked well, but for some years during heavy rains the sewer is incapable of holding the amount of sewage which comes into it, and it overflows into the basements of the houses in the neighbourhood, and in some instances it has flowed through the gullies or traps on to the main road. On one or two occasions he has known it force open the man-holes, when locked, in Greenwich Marshes, and flow through the ditches into the Thames in considerable quantities. It raised the level of the water in the ditches several feet, 6873–91, 6903. This has happened within the last three years during an exceptionally heavy fall of rain, 6892–7. The Metropolitan Board of Works are now constructing a new sewer which runs from the Lewisham district and joins the old sewer at Deptford Creek, which will relieve the Lewisham district, 6898–902, 6905–10. The pumping station at Deptford is insufficient for taking away the whole of the sewage that comes into it, 6903, 6911–2.

## Mr. GEORGE ROBERT MASON, Lower Road, Deptford.

Market Gardener, and Member of the Deptford and Greenwich District Board of Works and Local Board.

Capacity of the Drainage System as compared with the Demands upon it; Influence of this on the Storm Discharges.—Has known the sewer in Greenwich Marshes to overflow after a heavy rain and emit a large quantity of sewage. On one occasion it blew the tops of the man-holes off. The water flowed into the ditches and from thence into the Thames. The overflow has happened more than once, 6913–21, 6927. His attention was drawn a fornight ago to an accumulation of garbage in Deptford Creek, which came from the storm outfall there. There was about a cartload of it, 6922–4, 6930–1, 6936. Believes the sewage has caused damage to barges in the creek, 6925. His Board has more than once complained to the Metropolitan Board of Works about the overflows, 6928–9. His tenants in Deptford have complained to him of the stench from the river, which is continually getting worse, 6917.

## Mr. GEORGE JAMES SYMONS, F.R.S.

Past President and now Secretary of the Meteorological Society.

Rainfall to be provided for.—Is editor of a publication on British Rainfall, and receives returns from over 2,000 stations in the kingdom. Almost exclusively, since 1860, he has devoted his attention to the distribution of rain, 6937–40. Until recently rain-gauges have been used which were only capable of giving the total fall during 24 hours, and not showing during what period the rain fell. Since 1875 gauges have been constructed which are self-recording, and write down the quantity minute by minute as it falls. There are four such gauges in the metropolis, 6941–2. One of these gauges is at Greenwich Observatory, one is at Mr. Latham's at Croydon, a third witness has at Camden Square, and the fourth is at Kew, 6942. Hands in a book containing the results of Mr. Baldwin Latham's observations on rainfall at Croydon, 6942. The observations published from Kew he has carefully considered, and as possibly the sewage does not pass through the sewers at an uniform rate, they might be capable of taking $\frac{3}{100}$ths of an inch of rainfall per hour instead of half that amount as suggested by Sir J. Bazalgette. Besides in very dry weather $\frac{1}{100}$th of an inch would not flow into the sewers, therefore in his calculations he has allowed $\frac{4}{100}$ths of an inch per hour, and on this basis he has carried out his investigations for four years, which give very nearly the same results, and he does not think it necessary to go further back than 1880. He has prepared tables which contain the hourly rainfall at Kew on days on which the fall reached or exceeded one inch per diem (·04 of an inch per hour equals ·96 of an inch per diem), 6943, 6949–50. The abstract shows that in 1880 there were 83 days, in 1879 there were 95 days, in 1879 there were 82 days, and in 1877 there were 104 days, when there was a fall of ·01 inch per hour and upwards, giving an average of

MR. GEORGE JAMES SYMONS—*continued.*

RAINFALL TO BE PROVIDED FOR—*continued.*

91 days per annum. During the same period the total number of days when the fall reached ·10 inch per hour or upwards were 41, 37, 38, and 35 respectively, giving an average of 38 days. *He hands in these tables*, 6943, 6952–4. He ascertained 15 years ago that the number of days in the year on which the rainfall in the whole 24 hours exceeded a quarter of an inch was 35 days ("British Rainfall," 1867, p. 28), 6944–5, 6955. Since that period the rainfall has been above the average for the last few years. Not being an engineer, he is unable to say whether a quarter of an inch of rain would come into the sewers at any appreciable time of its falling, but everyone knows that with violent rain it rushes into the sewers, especially where it falls on macadamized roads and pavements, 6956–7. Hands in some tables which represent in a convenient form the amount of rain measured at certain places, of which the names are inserted thereon, and of which the positions are shown by numerals on the maps which he hands in (*see* evidence of Mr. Whitaker, F.G.S., following this evidence, with reference to the maps). *See Appendices F. and G. for these tables*, 6946–7. Hands in a diagram showing by columns the amount of rain falling at Oxford as representing the upper watershed of the Thames, and at Camden Square as representing London. These will form a rough guide to the Commission as to the distribution of rain, 6948. The total annual rainfall in London is 24½ inches, 6951. He has no record of the area over which the quarter of an inch of rain falling extends, but no doubt it should be known in calculating the amount which enters the sewers. He is, however, sure that there is nothing exceptional in the frequency which is shown at Kew. Very heavy rainfalls of two or three inches in an hour or two are intensely local, and does not apply to values such as are given in his tables. A fall of upwards of an inch per hour is usually a local fall, 6958–66. In five years he has had two instances of 2¾ inches of rain, and there have been perhaps eight or ten falls exceeding an inch per hour, but he adheres to his original statement that the average of 90 days is not disturbed to the extent of 10 per cent. by local falls, 6967. The fall of rain registered at Kew may be taken as a fair sample of the general rain over the metropolitan area, 6973. Sir J. Bazalgette's statement "that a quarter of an inch "of rain in 24 hours is an extraordinary thing" he does not understand, for it seldom rains without $\frac{1}{100}$th of inch falls, and in his tables there is no entry taken out which does not exceed ·04 inch, and the great bulk of the entries is much larger. He has underlined in the tables all the instances which exceed $\frac{1}{10}$th of an inch per hour, and they are ten times the quantity which Sir J. Bazalgette speaks of, 6974–6. The general difference between the minimum and maximum varies from $\frac{5}{10}$ths inch to $1\frac{9}{10}$ths inch, 6978. At Hampstead 4¼ inches fell on one occasion in 24 hours, and at his house 2¾ inches fell in 1¾ hours. It was the heaviest rain he ever knew, and the New River Head on that occasioned registered under half an inch, 6977–9. On one occasion he noted a rainfall $1\frac{1}{10}$th inches which had fallen equally over the metropolis. He compared it with the whole of the South of England, and there was a difference only of $\frac{1}{10}$th inch at all the stations up to the latitude of Bedford, 6980. Heavy rains as a rule are rains of very short duration, and his tables show when they were short or long, 6981–3. If it is desired he will tabulate the rainfall at Camden Square for comparison with the rainfall at Kew, 6984.

MR. WILLIAM WHITAKER, B.A., F.G.S.

EFFECT ON WELLS NEAR THE RIVER.—Has been engaged on the Geological Survey of England for more than 25 years, and has mapped the greater part of the Thames Valley, 6985–9. The question of water in the chalk is a subsidiary subject to which he has paid a good deal of attention, 6990. It is a very common thing in the Thames Valley, as along other water borders, that wells should rise and fall with the tide to a greater or lesser extent, and in some cases the water in the wells becomes brackish by reason of the infiltration of river water, 6991–3. He describes at length the geological formation of the Thames Valley above and below London, 6994, 6999–7016. Between London and Windsor there is very little chance of infiltration of water through porous strata into the earth owing to the impermeable bed of London clay along the course of the river. Its thickness varies from 300 to 400 feet.

MR. WILLIAM WHITAKER—*continued.*

EFFECT ON WELLS NEAR THE RIVER—*continued.*

The gravel which forms the bed of the river lies on this clay, 6995–8. Of the beds below the London clay (going down the river), which are four in number, the Blackheath beds, consisting of sand and pebbles, the Thanet sands, and the chalk are thoroughly permeable throughout, but the Woolwich beds, which consist of clay, sands, and pebbles, are permeable only as regards the two last, 7004–16. The deposits of mud on the bed of the river would to a certain extent prevent infiltration of water into the permeable strata, but at the bottom of the river there is really very little mud. Where it does exist it is simply local, 7017–8. Below London there is plenty of opportunity for the infiltration of river water into the beds from which the water supply may be drawn, and if the river is charged with sewage, naturally the sewage will permeate into the beds. If water be pumped from these beds to any extent it tends to lower the fresh water and to produce a cone of exhaustion which might result in drawing in the foul water, 7019–23. There were two pumping stations of the Kent Waterworks Company at Charlton, about a third of a mile from the river, but the company has discontinued the use of these wells for some years, 7024–7, 7045–6. It would take some time for wells to become polluted, because the river would not contain enough foul matter to have any effect for a long time, and it would take some time before the pumping at the wells would draw in such water. As the pollution of the river increases, and the pumping increases, conditions are set up which are favourable to the drawing in of river water into the wells, 7028–30. The chalk basin under and around London is a great water-bearing stratum, and where it is bared to the river it would feed the river under natural conditions. It is also the case, though to a lesser degree, that the chalk in the upper beds is a water-bearing strata, but there would not be so much pressure there, 7031–6. Has not gauged any wells in order to observe the fluctuations with the tides, but has received records and information on the subject, 7036–9. The chalk at its outcrop gets a considerable amount of rainfall into it, 7042. If a well is sunk near the Thames it draws water equally from the uplands as from the river side, 7043–4.

MR. EDGAR SHAND.

Manager of the London Steamboat Company.

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Was born on the banks of the Thames, and has been conversant with the river all his life, 7047–9. Has seen the sewage discharged from the outfalls, and has been able to trace it. Has seen the sewage flowing up and down in all parts of the river, but more particularly between Greenwich and Woolwich. It was very bad at Woolwich, 7050–5, 7067, 7071–2. The river was worse in the summer of 1881 than he has ever seen it. It was very thick, with a sort of glutinous matter, and bubbles rose and burst, and he saw nightsoil floating about. The smell was fearful, especially when the paddles of the steamers stirred it up. He has received frequent complaints of the filthy condition of the water from passengers, the captains, and the men on the boats, It has made them sick. In the winter the water is much better, 7056–64, 7070. Is on the river daily in the summer time between Greenwich and Woolwich, 7065-6.

MR. HENRY JONES, Woolwich.

Fisherman.

POPULAR EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Has known the river for a long time and used to gain his living by fishing. Now he collects the fat off the river from a boat by means of a landing net, and steams it on a barge he owns which is moored in Barking Creek, 7073–84. The fat is blown by the wind to various parts of the river, but he finds it principally in the bays of the river from Blackwall to Purfleet. There is often a large quantity in Barking Creek which comes from the outfalls, and when there is no wind they collect the fat at the outfalls. There is no disagreeable smell from the fat, which, when steamed, he sells; but he does not know to what purpose it is put, 7085–92, 7095–8, 7100–6. He generally starts to collect the fat on the half-flood tide, but he is dependent to a certain extent on the direction of the wind, 7093. He enjoys pretty good health, 7099.

### Captain HENRY WEBB.

Captain of the Steamer "Cupid," plying between Woolwich and London Bridge.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been employed on river steamers for nearly 40 years, and holds a Trinity House pilot certificate. He knows the river thoroughly, 7107–10. Prior to the opening of the outfalls the river between Westminster and Woolwich was worse than it is now; but the outfalls have made the lower part of the river foul and cleared the upper, 7111–5. Above the outfalls in the summer time he has seen the water very black and smelling badly, and he has frequently had complaints from the passengers of the stench from the river. It was worse the year before last. The steamers stir up the mud at the bottom of the river. It is worst from Barking to the lower part of Half-way Reach, 7116–22.

Offensive Odours.—When the steamboats get under weigh the paddles stir up the mud, which causes a very great stench. It is also very bad when two boats pass or run down together. The passengers have to keep their handkerchiefs to their faces to avoid the smell, 7116, 7120–1.

Set of the Tide.—Is acquainted with the tides in the river, and the flood tide is stronger than the ebb tide, 7123–4.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He enjoys very good health, and seldom requires the services of a doctor, 7125.

### Captain THOMAS HUNTINGFORD.

Captain of the "Duke of Edinburgh," belonging to the London Steamboat Company.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He holds a Trinity House certificate as master and pilot, and has known the river all his life, 7126–8. The sewage when discharged from the outfalls extends 200 yards into the body of the river, and the line is clearly shown by the colour, 7129–31, 7156–8. In Half-way Reach the water is never clear owing to an eddy, from which the sewage never gets away, 7132–4. From Bull's Point, abreast of Woolwich Arsenal to North Woolwich Pier, the water is in a very bad condition, and the stench there is worse than at any other part of the river. The first quarter flood sets in there, and a down current brings it back past the Gardens to Bull's Point, so the sewage cannot get away on account of this eddy, 7139–43. There is a drain pipe, two feet in diameter, near the Telegraph Works, above the Ferry Pier, but he has only seen water come from it after heavy rains. He has never noticed any smell from it, 7144–51, 7155. The pipe comes down to low-water mark, 7154. He has traced the sewage from the outfalls nearly a quarter of a mile up the river up to Halfway House Point, and down the river to Jenningtree Point; after that the river becomes one colour, but very thick in both directions, as far as Greenwich and Greenhithe, 7156–67.

Offensive Odours.—From North Woolwich Pier to Bull's Point the smell is very bad, and the paddles of the steamers stir up the mud and throw up the scent from the river, 7139, 7152–3.

Set of the Tide.—There is not sufficient run of the tide to carry the sewage through Halfway Reach after the first quarter flood or ebb tide, for then an eddy begins to form on account of the tide setting strongly from Jenningtree Point to the Dagenham shore on the flood, and from Halfway House Point to Dagenham on the ebb. A north-west wind would carry it away lower down the river, 7135–8.

### Mr. EDWIN MARTIN.

Pier Master at South Woolwich.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Has been stationed at South Woolwich for 18 years, and was pier-man before he was Pier Master. Prior to that he was in the Navy, 7168–72, 7190–6. The water in the river was in a much better condition and clearer then than it is now. Flounders and shrimps could be caught there, 7173–5. When the sewage is discharged on the flood, the water becomes very black, and little balls of fat float past, especially after heavy rains or snow, 7176–82. Has seen these balls of fat hundreds of times this summer, 7188–9.

### Mr. EDWIN MARTIN—*continued.*

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—At times mud collects about the pier, and sometimes it shifts. The tugs stir it up, and the stench is simply awful. The mud is of a bluish black colour, and is not at all like ordinary Thames mud with which he is familiar, 7183–6.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Has been absent from duty for three days at a time, twice this year through illness, but he cannot positively attribute it to the smell from the river or the mud, 7187.

### Mr. BALDWIN LATHAM, F.G.S., F.M.S.

Member of the Institution of Civil Engineers.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—Is a civil engineer practising at Westminster, 7197. And has devoted his attention for a great many years to works connected with sewage and drainage, and to tidal outfalls, 7198. Hands in a report on the observations made in the river by himself. (*See Appendix R.*) Has taken the temperature of the water for many years, and knows at what temperatures it would become noxious. When at 60° or 65° to 70° it is noxious. Hands in two tables of recorded temperatures of the Thames, showing the number of days in every month when the temperature of the Thames water was above 60°, the number of days when it was above 65°, and the number of days when it was above 70°. The number of days when no observations were taken is also given. The maximum and minimum temperature for each month in the year, from June 1844 to October 1879, is shown in one of the tables, 7414–5, 8367–70. The temperature was taken at 9 a.m. daily by thermometers attached to the side of the "Dreadnought" till April 1870. From 12th January 1871 to May 1874 they were attached to the "Scorpion" in Blackwall Reach, and from that time until October 1879 the thermometers were fixed to the "Royalist," which was moored in the same place. The thermometer was immersed a foot below the surface in running water, 7416–23. Hands in a table of temperatures giving the monthly means, through a range of 35 years, of the principal elements of the temperature of the water of the Thames, compiled by Sir George B. Airy, K.C.B., F.R.S., 7430. The fact of the sewage staying in the river in hot weather, assuming it to be not mixed, tends to make it more noxious, because when the weather is hot, decomposition of the matter deposited and held in suspension takes place, and the tidal water is filled with the gases of decomposition, and is not capable of oxydising the impurities of the sewage, 7449, 8371–6. Hands in a table taken forom the analyses of Professor Way on samples of water taken in the river at various points between Chiswick and Margate, giving the amount of chlorine in 100,000 parts at high and low water on the 14th and 22nd of September 1882, and on the 30th November 1882, 7510–5, 7989–92. Given the amount of chlorine in one fluid and also in another, you can tell the amount of chlorine there ought to be in the mixture, and inversely, you can with the same data tell the relative proportions of the mixture, 7516–21. To find out in what ratio a certain volume of water is mixed, he uses the following formula:—

A=the chlorine in sea water.
B=the chlorine in the river water.
C=the chlorine in the mixed water.

Then $\frac{A-C}{C-B}$ = the exact result.

This is taking a simple compound, but where there are three separate fluids mixing, it can be dealt with in the same way. The object of these calculations is to find out by means of chlorine the proportion of sea water, river water, and sewage in every part of the Channel, 7516–24, 8321–30. Has worked at great length a more elaborate mode showing how this formula is deduced, and hands it in (*See* Appendix U.), 7525. Taking it generally, the object of these chlorine experiments is to distinguish what is sea water and what is not sea water. They are much more important down the river, and the lower down you go the greater is the effect of the mixing action, because if it did not take place, there would be the same amount of river and sea water all the way down, 7526, 7527. In making these calculations, he took the actual volume of water known to come down the river upon the same day, and a standard of sewage by taking five cubic feet per head of the population, because if there was anything to increase the amount of

MR. BALDWIN LATHAM—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

sewage, there would be the same amount of chlorine going in although in a larger volume. If it rained, the sewage would go into a larger volume of water. The amount of fresh water coming into the river every day at every point of the river is known, and so is the standard of sewage. He assumes the mixture of river water and sewage to be of the same proportion as the daily flow of the water and sewage, and knowing the amount of chlorine in each, it is easy to see what is the amount of chlorine in the two mixed. It is correct to assume that they are mixed in the ordinary proportions, because if there happens to be a larger amount of water coming down, it is measured in river water, while there is the same measure of chlorine coming from the population, 7528–35, 8484–9. The sewage and fresh water are mixed so as to form one fluid, which then mixes with the sea water. The amount of chlorine is taken as indestructable, 7536–9. Gauges have been placed in fifty different places, so that with the exception of the 284 square miles, which are equal to $\frac{1}{18}$th of the whole drainage area of the Thames, he has ascertained the quantity of water coming into the river every day, 7540–2.

The amount of chlorine in sea water is 1961 parts in 100,000. The amount of chlorine in fresh water is 1·7 parts in 100,000. The amount of chlorine in sewage is 10 parts in 100,000.

The amount of chlorine in a combination of sewage and fresh water varies in different parts of the river. Below Barking it is constant, but above it is less. For the purpose of ascertaining the relative amount of sea water and non-sea water it is not material to distinguish between the sewage and the fresh water, 7543–9. Hands in a table showing the amount of chlorine in 100,000 parts in the component volume of river water and sewage combined at 10 places between Teddington and Southend where samples were taken on the 14th and 22nd September, and the 30th November 1882, 7548. On the 22nd September there was 50 per cent. more water coming down than on the 14th September producing more dilution, and on the 30th November the river was in flood. It caused a difference of 40 per cent. less chlorine at Southend. The highest flood going over Teddington Weir is distinctly appreciable at Southend, 7550–6, 8315–30. The difference between this table and Professor Way's is caused by its representing the amount of chlorine in river and sewage water combined, whereas Professor Way's includes sea water, 7557. Chiswick may be taken as the vanishing point of sea water, and at Barking it is in full volume. If you take the mean between the two, it will show that there is only half the chlorine due to sewage in that part of the river which is observed at Barking, 7557–8.

The table handed in yesterday (*Q.* 7369) shows the quantity of river water in the mixture all the way up the river as well as how much sea water there is. For example, at Chiswick $\frac{1}{7.50}$th part of the volume was sea water; at St. Paul's Pier $\frac{1}{3}$th was sea water; at Erith there is about an equal quantity of sea water and of sewage and fresh water mixed, and so on, 7559–65, 8224–5, 8315–35. He now hands in an amended table showing the effect of the mixing action in the River Thames (*Q.* 7369). From it, it is found that as regards the upper reaches, the number of days it takes the sewage to get out is increased, but below Barking the results are not altered, 7566–7. Starting at Deptford, on the 14th September, the sewage discharged at high water from the outfalls would take 41 days to get to the sea, and 40 days at low water. On the 22nd September, there being more water in the river, it would take 34 days and 31 days at high and low water respectively. On the 30th November, the times are 16 and 12 days respectively. His reason for starting at Deptford is that the sewage, after being discharged, would be brought back to Deptford by the next tide, 7568–73. Displacement and mixing action have both been considered in these calculations. In flood time the mixing action and displacement are both greater than in dry seasons, the difference in mixing being 30 times taking the whole basin of the Thames, 7574–6. The want of sufficient capacity in the reservoirs, and the frequent discharge at other points of the river, leads to the pollution of the higher portions of the river, and shows that there is an accumulation of the sewage which would not otherwise take place, 7670. The outfall at the Beckton Gas Works was made in 1874.

MR. BALDWIN LATHAM—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

The average total quantity of water flowing out of it daily has been found by gauging to be 292,952. gallons, or 46,872 cubic feet, per day. No solid matter goes through the sewer, as it is filtered through coke, but the water smells very strongly of gas. There are 101 cottages on the property which drain into the sewer, 7912–16. By moving the sewage to Barking and Crossness from London, a vacuity was created in the upper part, which the tide has a tendency to fill. The result is that this removal has created a tendency for the tidal water to bring the sewage back again. He hands in a table of capacity of the River Thames, prepared by Mr. Mansergh to which has been added the volume of fresh water entering the river, between Teddington and Southend, and between Barking and Southend, 7917–29. Referring to the table of analyses by Professor Way on the chlorine in the river (*see Q.* 7511) he points out the difference existing between the amount of chlorine in the river at spring and neap tides, 7989–92. *Hands in a table*, showing the amount of chlorine at high and low water in the river from samples taken on the flood and ebb tide between 29th October 1882, and 7th November 1882, from Teddington to London Stone, 7993–4. Hands in another table, produced from chlorine tests, showing the quantity of upper river (Teddington) water mixed with each volume of tidal (Southend) water at various places on the Thames, 7997–8, 8226–32. The conclusion he comes to is, that the capacity of the sewers being inadequate for the district, sewage is discharged into the river at higher points, which naturally lingers longer in the river, and at certain periods of the year tends very much to increase the pollution of the river, thus rendering its condition very unsatisfactory, 7999–8003. He has seen the river this year bubbling up from the effects of fermentation and black in colour, and a year or two ago it was very foul between Deptford and below Erith. In the summer of 1878 the river was most frightfully offensive throughout the same district. It was like sailing on the top of a cesspool containing diluted cesspool matter, 8004–15. It is a fact, that sewage when mixed with sea water certainly undergoes a rapid decomposition, but his tables are not fallacious, because he was careful to put in the words "sewage and river water combined" in all his tables, 8389–94. He does not consider the discharge of sewage into a tidal river, where it mixes with sea water, the safest way of disposing of it, because his experience of sewage works in sea-coast towns have proved the discharge of sewage into the sea direct, to be a most frightful nuisance, 8395–9. So, in the Thames, the accumulation of many days sewage must create a nuisance, 8398. There is no "pure" water at Barking or Crossness on account of the fresh discharge of sewage at high water just after the last discharge on the ebb has ceased only a few hours, 8401–2. Extracts read from his book on sanitary engineering on the discharge of sewage into the sea, 8400–11. To get rid of sewage by decomposition is a slow process; if you select a tidal outfall at the proper point, it is got rid of at once; but if you put it into a river, it is washed backwards and forwards, 8412–4. Four parts of pure water to one of sewage is equal to the purest effluent sewage; the only pure water coming into the river is the upland water, and it is impossible for any sea water coming up as far as the outfalls to be fresh, because the tide runs up or down only 12·6 miles, so there is an interval between them of the distance of two tides, in which no water fresh from the mouth of the river or from the uplands can enter, 8414–8. Another thing to be borne in mind is, that the sewage is discharged only upon a certain portion of the water, and not upon the whole volume going down, 8419–21. Hands in some tables marked A. and B., showing the effect of the mixing action in the River Thames when the amount of sewage has been taken as 10 and 20 parts, 11,758.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—There is no doubt that, owing to the superior influence of the flood tide, matters of a certain specific gravity can be picked up and carried to a certain point and there dropped, and the ebb tide will not carry them down again, 7319. The parts which are heavier than the water are carried backwards and forwards, and, coming to rest at the end of each tide, are precipitated to the bottom of the river. This constant oscillation is most deleterious, especially

## Mr. BALDWIN LATHAM—*continued.*

### Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

in hot weather. The matter which is not deposited becomes more or less impure as long as the mixing goes on, 7447–8. The experiments, which were carried out by the Native Guano Company under the control of the Metropolitan Board of Works in 1872, were made for the purpose of testing the purifying result of the process and the amount of manure produced. The sewage experimented upon was stated to be 11,672,737 gallons, being $\frac{1}{3\frac{1}{4}}$rd of the average flow of the sewage discharged at Crossness, and $\frac{1}{6\,8\,6}$th of the sewage of London, 7434–39, 7875–82. By the A. B. C. process, the equivalent of 81 tons of dry material were added to the sewage, consisting of sulphate of ammonia, charcoal, and clay, with a little blood and lime occasionally, and this produced 142 tons of manure. Of this quantity, 26·45 per cent. was found to consist of water, and 104·441 tons of dry material remained. The result showed in the mixture there were 43·31 tons of solids in suspension, which is equal to 57·41 grains in a gallon. In a year it would amount to 135,096 tons in 1872, and at the present time it would amount to 197,647 tons of solid matter in suspension flowing into the river per annum, 7883–98, 8458–62. The dry matter produced by the population is 3½ ounces per head, or 138,789·5 tons a year. The difference between that and 198,000 tons of solid matter in suspension, is due to road scrapings and other foreign matter. This agrees pretty accurately with the amount stated by Messrs. Bidder, Hawksley, and Bazalgette in their Report of 1858, page 74, viz., 250 tons a day of solid matter, allowing for the increased population, 7899–7911, 8042–3, 8098–8115, 8377–88, 8463–9. The mixing action would affect everything in suspension which is capable of mixing, but it would not affect the solid matter which falls to the bed of the river. That could only reach the sea either by a sufficient velocity of the stream to carry it down, by gradually being dissolved if capable of dissolving, or else by decomposition. That which is capable of mixing would naturally reach the sea first, 7976–8. As the velocity of the flow of the sewers on the south side is greater than the velocity of the ebb tide the tendency must be for the sewage to deposit. On the north the balance is about equal. The tendency to deposit would increase as the velocity slackened, especially near the turn of the tide; and in slack places mud banks would be formed, 7979–83, 8038. This rule would not apply to deposit in sewers if discharging in a tidal river, 7984. The amount of deposit depends to a certain extent on the angle at which the sewers impinge on the river, 7984–8. The bulk of the sewage is brought to a state of comparative quiescence in the reservoirs when there is no flow into the river, and the reservoirs therefore become places of subsidence as the Metropolitan Board of Works intended they should be in times of storms, 8039–41. A certain portion of the solid matter in the river does not undergo a destructive decomposition. The quantity of mud brought down by the upland water is comparatively small and discolours the water only. The quantity of sewage introduced annually into the river is certainly not small compared with the total amount of mud in suspension, for the mud brought up by the tide is very nearly the same every day, but in the case of sewage a fresh volume is added daily, 8043–58, 8088–91. The average amount of matter washed into the river annually from the foreshore and the saltings is considerably less than the amount of sewage discharged into the river annually; it is less than a third of the quantity, 8059–65. It is quite possible that a proportion of suspended matter is beaten up in storms from the sand and mud banks at the mouth of the river and carried up by the inflowing tide at certain periods. It can, however, only be carried 12 miles. It is a very difficult thing in the Thames to decide what has been taking place from natural denudation, and what from constant dredging, 8066–7. It is utterly fallacious on the part of the Mud Inquiry Commissioners to say that the dry weather sewage contains on an average 23 grains of suspended matter per gallon. The correct quantity is 57 grains in the gallon. The difference exists in the omission on their part to consider the amount of added matter in the A. B. C. experiments, part of which went away in solution in the effluent water. This should have been deducted, 8068–87. The destructive process (referred to in Q. 8043) is the resolution of the sewage into its constituent parts. The mineral portion, such as road detritus, would be capable of forming sand in the bed

## Mr. BALDWIN LATHAM—*continued.*

### Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

of the river, and the strictly organic matter, which is no longer capable of depositing, poisons the water, and it is that which in hot weather really causes the river and mud banks to be so offensive. In the course of decomposition, certain parts of the constituents of the mud banks are given off in a gaseous form and pass into the water, 8088–97. Referring to his answer to Question 8,064, he wishes to state that the solid matter of which he was speaking with regard to the sewage, viz: the 200,000 tons a year passing into the Thames, is absolutely dry matter. But that is compared with the saltings of the river which are taken out in cubic yards, and calculated that a cubic yard in its natural state would weigh a ton. But he is now comparing dry matter with matter which contains 40 per cent. of water, so that the absolute dry matter in the saltings would be very much less than 41,417 tons, and the ratio of the dry matter of the sewage would be very much greater, and would be more than six times as much as the dry matter of the saltings, 11,758.

Effect upon Health in the neighbourhood of the Main Outfalls.—Hands in tables showing the population, births, and deaths, with the rates of births and deaths, per 1,000 at Barking, Grays, Dartford, and Gravesend from 1871 to 1881 inclusive. These comprise the towns within the registration districts as well as those named. The figures show considerable fluctuations in the death rate which are not really consonant with very healthy districts. The most unhealthy district is Dartford, which includes Erith, 7930–4, 8357–66. By dividing the births by the deaths, a more satisfactory result as to health is obtained than if the death rate alone is considered. The larger the proportion by which you can divide, the healthier is the district. The average condition of health in a district should show the births twice as numerous as the deaths, 7935–43.

Effect on Wells near the River.—He believes the discharge of sewage into the river affects the wells in the neighbourhood. In 1878 he investigated the sites chosen by the Metropolitan Board of Works for the purpose of supplying London with water from the chalk formation, one site being at Grays in Essex, 7944–50. Samples were taken from the wells at Grays and Erith which were submitted to the chemist for analysis, 7951–3. In 1878 levels were taken of the water in all the wells in the neighbourhood, and it was found that when pumping was going on at the quarries, all the water fell to the point of exhaustion, and it was also ascertained that there was a direct flow from the Thames itself to the spot chosen for the water supply, 7954–5. Pumping at the chalk quarries affects the water for miles round, and by pumping at the Grays quarry, the water at Gibbs' chalk quarry, distant one mile, is immediately lowered, 7956–8. From analyses of the water taken at Grays some time ago, the water in the wells contains 1·4 parts of chlorine per gallon, but it varies according to the state of the tide. The recent analyses show that there is an average of 23 gallons of river water mixed with 1,000 gallons of the water from the district, which tends to prove that the sewage would get into the wells. At Erith, in one instance in 1882, assuming that all the chlorine was due to the river and none due to leakage from cesspools, one-third of the water in the well had been in the river, 7959–65, 7971–5, 8016–21. The water when it contains chlorine becomes unhealthy, 7966–70. In Table 9 of the Report of the Metropolitan Board of Works Engineers, upon main drainage, dated 1858, the statement that there are several wells along the shore near low water line containing fresh water, not at all brackish, is quite correct with regard to the water in its natural state, but that condition is immediately altered directly pumping begins in the neighbourhood. Exhibits a sketch which illustrates the theory of tidal wells, 8022–4. He mentions a well at Plymouth which is absolutely dry at low water, but at high water it fills with fresh water and overflows into the tidal way. If any exhaustive pumping were going on, the tidal water would enter, 8025. The chalk in the London basin is fed from the highlands both on the north and south sides of the river, but the quantity of water varies immensely, 8026–7. He hands in a report dated 17th September 1860, by Dr. R. D. Thomson, on the water from the springs at Grays, Essex, the analysis showing 2½ grains of chloride of sodium per imperial gallon, 8028. The analyses made of the samples which witness took

MR. BALDWIN LATHAM—*continued.*

EFFECT ON WELLS NEAR THE RIVER—*continued.*

showed 13·6 parts per 100,000 parts of chlorine at high water, which in his opinion is a most unusual thing in fair chalk water. Dr. Tidy who made the analysis will produce it, and give evidence on the subject as well, 8029–34. He has collected statistics on chalk from the North and South Downs as well as from Yorkshire, and his experience shows that except in wells near the sea (where a greater quantity will be found) so large a proportion of chlorine in inland wells, viz., 13 in 100,000 parts, is enormous. The analysis was only made for his own instruction, not to ascertain whether there was evidence of sewage contamination, 8035–7, 8116. The wells referred to at page 104, Sixth Report, Rivers Pollution Commission, 1874, are totally different to the ordinary chalk water wells, as the chalk is overlaid by other geological formations, 8117–24. The wells further inland than Grays show that they have not the same amount of chlorine in them, nor are they influenced in the same way. The standard amount of chlorine in distant wells near Erith is 1·4 per 100,000, 8494.

DISCHARGE FROM THE STORM OVERFLOW OUTLETS.—If the sewers are not large enough to take the sewage and quantity of rain which they were designed to take for a greater number of days or periods than was contemplated, then the overflows must act, and whatever brings these overflows into operation, must lead to a greater degree of pollution of the river in the higher parts, because it takes much longer for the sewage to get out of the river, 7686. On the south side of the river the ratio of the flow in time of rain to the mean flow is 2·76 to 1, so that if the rain is double the sewage it would fill the sewers, and upon the average every time it rained in London the sewers must overflow at some point or another, 7824–9, 8129–33. Has never taken any samples when a discharge was going on, but he believes samples have been taken and analysed. The discharge from the outlets is much more filthy and much more concentrated sewage than that which is discharged at the main outfalls. More overflows are now being constructed, the effect of which will be to bring the sewage and rainfall combined to a greater extent into the upper parts of the river, 8498–9.

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER.—Some months ago he was requested by the City solicitor to investigate the discharge of sewage into the Thames, and in this he was assisted by Mr. Mansergh and Mr. More as engineers, and Mr. Birch was engaged to look after the float experiments, 7199–201. To ascertain the horizontal range of oscillation of the tides near the northern outfall, a series of floats, (similar to the one exhibited to the Commission) were put into the Thames, and their motion watched day and night by men in small boats, superintended by Mr. Birch and his staff from a steamer, 7202–3, 8422–9. The dimensions of the floats are 12½ feet in length, and 11½ inches in diameter. In shape they are octagonal in order to offer as nearly as possible the same surface to the water if they revolved; they would stand vertically in the water, and the minimum and maximum heights of the floats out of the water are 6 inches and a little less than a foot respectively. On an average they were immersed 12 feet. Salt water would raise them a little on account of its additional buoyancy, 7204–10. Use has been made of the existing recording gauges on the Thames, and others have been erected, especially in the lower part where it was most important to carry on observations with regard to the rise and fall of the tide, 7211. The total drainage area of the Thames is 5,162 square miles; and the Thames, and all the tributaries which it was possible to gauge, have been gauged, because it was of importance to ascertain the volume of the water coming into the river at all points, 7212–14. The drainage area of 5,162 square miles includes the Thames and its tributaries from its source to its tributaries from its source to its mouth (*see* Mr. Symons' plan), with an average breadth of 50 miles. The length of the channel of the Thames is 201 miles. About 500 square miles are due to the drainage area of the River Lea, 7215–24. The quantity of water in th river below the outfalls is of great importance fo the purposes of his deductions, 7225. The quantity of water flowing from the draining area has been gauged with the exception of 284 square miles, operations having been carried on at 50 different points. The quantity of water flowing from the 284 miles has been arrived at by taking a similar area below Teddington Lock, and making calculations therefrom, the

MR. BALDWIN LATHAM—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

result is shown in the table of gaugings. The ungauged portion represents one-eighteenth part of the whole drainage area, 7226–8. The statistics contained in his Report are the results of his own actual inspection and supervision, and from the observation of those who watched the floats; on many occasions he personally observed the floats, though obviously he could not always do so, 7229–36, 8422–9, 8500. The distance from the northern outfall to Crossness is a mile and a half. From the northern outfall to Erith Pier is five miles. From the same outfall to the Town Pier, Gravesend, is fourteen miles and three quarters, and from the same point to Cliffe Creek is eighteen miles and three quarters. The whole of the river has been very carefully surveyed with the view to arrive at the capacity of the river from the area of the cross-sections, and he has used these sections in making certain calculation, 7237–42. The sewage when turned out from the outfall flows down with the tide to a certain point, and is brought back again by the next tide to a certain other point up the river. This process of oscillation would go on for a longer period than one "lunation" (that is, 14 days, 7292), until it is dispersed and gradually driven out of the river by the fresh upland water, 7243–5. The "mixing action" has, however, a much more powerful influence on the sewage than the actual displacement. The sewage flows into the tide, which, as it goes down comes into a larger area of water, which is mixed with salt water. From the fact of its having flowed into a larger volume of water, it is returned more diluted than if it had been in a parallel channel of small size all the time. The mixing takes place also by the influx of fresh water. If there was no mixing action, the water from one range of the tide would be found to be fresh at the mouth of the river, whereas sea salt has been found in the river at Chiswick, 7246–52. The results of his observations on the distribution of sewage, as shown by the "float" experiments, are given on the diagrams he hands in (*see Appendices S. and T.*), 7254, 7995–7, 8134–40, 8431–49, The experiments began on the 17th September, and the first float was put into the centre of the river at high water opposite the northern outfall. It drifted down 15·84 miles with the tide (which was just after spring tides). After seven days of drifting it reached a point just opposite Higham Bridge. It drifted 2·08 miles above the northern outfall on the 29th September. On that day it was a spring tide, when the water flows up more rapidly than on a neap tide, 7253–67, 8169–72. The float was lost in a fog on the 13th October, but was started again the same day in the same position it held, with No. 4 float, as when lost. A hitch in the management of a float is shown on the diagram by a black dot. The observations continued until the 24th October, when they were stopped by the unsettled state of the weather, 7268–73. During the 45 days this float was in the water it only progressed 2·20 miles down the river from its starting point. Taking two complete lunations, the progress was only two miles, and in 26 days, when there was no break, the progress was only 1·76 miles below the northern outfall, 7274–6. As regards No. 2 float, which was in from 17th September to 19th October, a doubt as to its whereabouts is shown on the diagram by a dotted line. It was put in at half tide, and at the end of 31 days it had advanced 1·3 miles up the river. When the floats grounded the men had instructions to haul them straight out into the stream, 7277–95. No. 3 float was in for 43 days, and was put in at low water; at the end of that time it had descended 13·80 miles down the river. These three floats were all put in just when the tides were taking off after spring tides, 7296–300. Floats Nos. 4, 5, and 6 were put in at neap tides, at high water, half tide, and low water respectively, and their movements are accurately recorded on the diagrams, 7301–2. Upon afternoon tides the range is greater than it is upon morning tides, and this fact will show that the floats could not have been anchored during the night, 7326, 8428–31. The last diagram but one shows the phases of the moon, the direction and velocity of the wind, the amount and condition of the tide, spring or neap, and the quantity of water flowing every day in cubic feet over Teddington Weir. By multiplying the number of cubic feet per minute by nine, and add three cyphers, it gives the number of gallons in 24 hours, but for his calculations he has used a multiplier of 6¼, 7304–9. The last diagram refers to some experiments made with regard to the mixing

Mr. BALDWIN LATHAM—*continued.*

Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

action, 7303. They were made with a view to apply practically the results theoretically arrived at from the amount of chlorine found at various points, 7311–2*a*. At certain phases of the tide, when more water is coming into the river, that is, when the tides are making, the tendency is for things to drift higher up. At other times the tendency is for more water to flow out and things drift down, but it may be modified by the wind or the quantity of water coming down from Teddington and the tributaries of the Thames, 7313–8. The ebb tides are much longer than the flood tides in their apparent flow, and, taking the relative velocity of each, it will be found that the velocity of the ebb is very much smaller than that of the flood. The velocity of the flood is 192·2 feet per minute, while at the ebb it is 167·6 feet per minute. The flood runs up for 5½ hours, and the ebb runs down for seven hours at Westminster. If there be a tendency to a greater flow of tidal water along the bed of the river, as is shown by experiment, by the greater amount of chlorine, it has then a tendency to accelerate the motion of a float up the river, 7321–3. A float was kept continuously going down with the ebb from Teddington to Southend, and a corresponding float was always coming up. Samples of the water were taken at various points and at similar states of the tide, on the surface and at half the depth of the river, which were submitted to chemists for the purpose of ascertaining the amount of chlorine they contained. Owing to the powerful stream of upland water coming down on the 4th November, the float put in on that day at Yantlet Creek was not able to work up the stream. On the 3rd November the volume of water coming over Teddington Weir was 711,000 cubic feet per minute, and on the following day it was 627,547 cubic feet per minute. The lowest volume has been 74,279 cubic feet, 7324–7. It takes about three days to work a float from Yantlet Creek to the Commercial Docks, as the greatest amount of tidal water is found there, but higher up the progress is much slower. At points where the upland water is large, there is a greater flow downwards, and the more tidal water the river contains in proportion to upland water, the longer sewage will oscillate, but the more it mixes, 7328–30. On his own diagram he has put figures showing the amount of chlorine in the various samples of water, which are taken from the analyses of Professor Way, 7331–3. Has prepared a table (which he hands in) showing the effect of the mixing action in the River Thames at high and low water. The results are obtained by taking sewage as containing 10, river water 1·7, and sea water 1,961 parts of chlorine in 100,000 parts. The number of days is calculated from the gaugings of the total flow of the River Thames, on each day. In this case all the upland water is assumed to enter the river at Teddington. This table shows the result of the experiments and the effect of the mixing after his calculations upon the 14th and 22nd of September and the 30th November 1882. The places to which the various mixing experiments apply are given; at Teddington chlorine was found in the water, which was due to the river water and sewage, 7334–44, 8291–303. The water as it comes over Teddington Weir has chlorine in it, and the standard of 1·7 is assumed to be the initial quantity due to the river, and is the mean of the whole, 7345–8. The calculations have been very carefully made with reference to the quantity of chlorine which is due to the presence of sewage or sea water, because it has been taken for granted that wherever sea water is carried past the outfalls, there sewage might be carried past, 7349. The proportion of chlorine in sewage is nothing like the amount in sea-water, but whenever chlorine is found, the inference is that sea-water has got up to that place, 7350–1, 7354. The calculation that if a particle of sewage were put in at Teddington it would take 1·71 days to reach Cniswick, is based upon the capacity of the section of the river and the total quantity of water coming down the river. The tables were compiled in a hurry, and on the assumption that water only came into the river at Teddington, whereas it comes in at various points. This has now been corrected *and an amended table is handed in*, 7360–2, 7369. A particle of sewage would take 31 days to get from Barking to Southend on spring tides, 7364–6. On the 22nd September there was about 50 per cent. more upland water in the river than on the 14th September, assuming 157,745 cubic feet of water to be coming down per minute on a neap tide, 7367–73. On the 30th of November the river was in flood, and the tide was neap tide. The total quantity of water on that day coming into the river is

Mr. BALDWIN LATHAM—*continued.*

Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

estimated at 557,000 cubic feet per minute (treated as all coming from Teddington), 7376–9. Sewage at high water would take 27½ days to go from Barking to Southend on a neap tide and nearly the same time at low water. With the river in flood, the time would be 14½ days at high water, and about 13 days at low water, 7374–5, 7380–1. He had considered the question of mixing before the chlorine experiments were made, and the tests were taken to see whether the original samples would confirm the view as to the change going on through the river, 7382. That there is less area occupied by sewage and river water where there are two outfalls than where there is only one, is due to the fact that there is a constriction in the cross-section of the channel at that point. The area of the cross-section is arrived at by putting an imaginary division, one foot in width, across the river and finding the superficial area of it, 7383–6, 7392–3, 8291–2. Judging from the quantity of chlorine at Barking, out of a total of 65,791 square feet, there are 40,852 square feet of sewage and river water combined. At Crossness there is more sewage and more sea-water, 7387–91. Taking the average condition of the river, the quantity of fresh water coming in is about 30 cubic feet per minute per square mile of drainage area, which would represent 157,000 cubic feet a minute of which 122,000 comes over the weir. In dry weather it would go down to 12 cubic feet per minute per square mile, 7394–403. There is nothing in the table which would represent a drought period, 7404. In a maximum flood, the quantity would be 360 cubic feet per minute per square mile, or 1,304,000 cubic feet on the whole area, of which 1,053,000 would come over Teddington weir, 7405–8. In a dry period sewage would take a much longer time than is given in the table to be carried from Barking out to sea, but without an experiment it is impossible to know the exact time for certain. In flood time it would probably be carried out in a week, 7409–13. Low water at Southend on the average of tides was higher, between September and November 1882, by 1·87 feet than at Deptford, by 1·06 feet than at Gravesend, by 1·52 feet than at Erith, and at high water it was, during the same period, 2·06 feet lower than high water at Deptford, taking it from the mean sea level, 7424–9 This shows, as a curious fact, that the river in flowing down does not obey the ordinary law of water, moving down hill because it moves up hill. It is moving by tidal impulse, 7431–3. The reservoirs having been constructed on such a level that they cannot be emptied ordinarily until three hours after high water, the first part of the sewage discharged flows down 12 miles, while the last part would only flow six miles, and the next tide would bring the last outflow six miles above the outfall, it having been discharged three hours after the first. The ebb goes at the rate of two miles an hour, so there would be a section of six miles of river occupied by sewage, and the next section would have no sewage in it. The Metropolitan Board of Works have always taken 12 miles as the range, but 12·6 miles is the average range of all his experiments. The level of the floor of the reservoir is 2·75 above the ordnance datum, so the discharge cannot begin until three hours after high water, 7440–6. On some occasions deep floats were used, and at other times surface floats. It was found that in ascending the river the surface floats moved with less velocity than the deep floats, but in descending the river, the reverse was the case (*vide* page 37 of Mr. Latham's Report), 7460–3. The times of ebb and flow vary, the flood being shorter than the ebb throughout the river. They are nearer in the lower part of the river, and more unequal in the upper part of the river. For example, at Teddington there are only two hours of flood and 10 hours of ebb, while at Southend there are 6 h. 3 m. of flood and 6 h. 22 m. of ebb. There is also an increased range of tides in the Thames to what there was formerly. It is due in a great measure to the gradual deepening of the river from dredging operations, which tends to accelerate the flow of the tidal wave and make it greater, 7464–74, 8470–2, 8495–7. From the observations taken during a period of three months the mean tide level has been deduced. The mean tide is half way between high and low water.

The mean tide level is above the ordnance datum:—

| | |
|---|---|
| At Deptford | 1·98 feet. |
| At Teddington Lock | 11·00 ,, |
| At Erith Pier Pier | 1·96 ,, |
| At Gravesend Pier | 1·94 ,, |
| At Southend Pier | 1·89 ,, |

MR. BALDWIN LATHAM—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

The mean at the outfalls would be between 1·96 and 1·98.

The Metropolitan Board of Works take their mean level to be 1·5 half tide. It also shows the mean high water to be 11 feet above ordnance datum and the mean low water to be 7 feet below. This shows that 1·5 is incorrect and the mean should be 2 feet exactly, 7475–84. The average range of the tides as ascertained by the float experiments is 12·6 miles on the flood and 12·64 miles on the ebb. As the distance from the Nore to the outfall is 36 miles, the sea water would travel 12 miles, and there would be an intermediate 12 miles in which no sea water at one end and no fresh water at the other end would enter. Sewage would be carried upon an average 12·6 miles, 7485–93. The tidal wave acts by impulse on the body of water at the mouth of the river and propels it up the river. If there were no mixing action going on, the water at the lower end of the river at low water would be identical with the water 12·6 miles higher up at high water. Mixing action is principally due to currents, while the ebb is running down, the flood is running up the sides of the river, 7494–5. Without any mixing action there would be a body of water constantly oscillating in the Thames, and it would take 300 tides before anything put in at Crossness would travel 12 miles, 7495–500. Salt water advances up the river as the upland water decreases, so in a dry season it gets up higher than in a wet season, 7500*a*–3. The tidal wave moves with a velocity equal to that which a solid body would acquire in falling a distance equal to half the depth of the channel. In a rectangular channel, the velocity is equal to the square root of half the depth. In the Thames from Southend upwards, the velocity of travel of the tidal wave is fifteen times as great as that of the ordinary flow of the tidal current, 7504–5. In the spring and autumn the period when the upland water exceeds the average is longer than when it is below the average. There are exceptions sometimes during summer floods, 7506–9. The difference between high water at the Nore and London Bridge is one hour and a half, and between London Bridge and Teddington is one hour and 20 minutes. It is a difficult matter, however, to say exactly when it is actually high water at Teddington, because the top of the tidal wave only is recorded, 8140–55. As morning tides he classes any tide of which the largest part is between 12 midnight and 12 noon. As afternoon tides he classes those tides the largest part of which is between 12 noon and 12 midnight. So that high water at 2.30 p.m. would be a morning tide, and high water at 4 p.m. would be an afternoon tide, 8159–68, 8473. At the time of the "float" experiments, the range of the tides was greater in the afternoon than in the morning, which explains the fact that the floats went up further on the afternoon tides than they went down. There is a diurnal difference in the period of the tide which is greater in the afternoon. It would occur upon the flood tide only, 8172–4. The diurnal fluctuation in the flow of the tides affects the afternoon tides in the winter, and the morning tides in the summer. Whatever varies the height of the tide must also vary the velocity of flow. When the tides rise higher they also fall lower. There is also a greater difference of proportionate velocity between the flood and ebb tide, 8175–89, 8430–51. Mr. Latham was here cross-examined by Mr. Bidder at some length on the float experiments, who handed in diagrams representing the course taken by the floats, and challenged Mr. Latham's diagrams as being absolutely worthless. Mr. Latham explained that the diagrams he himself handed in, showed the true course of the floats as they were all in different parts of the river, some going down, while others were going up. The amount of land water coming down would also affect their progress according to their position in the river, as in the lower part of the river it has less effect than in the higher and narrower part, 8190–9, 8234–90. Taking the mean effect all the year round, and if there were no mixing action, the sewage ought to pass Crossness at the rate of three-quarters of a mile a day, but by reason of the mixing action it goes much quicker, 8200–8. The floats have nothing whatever to do with the question of displacement. One simply shows the oscillation of the tides, and the other shows what is the natural displacement in the river by the quantity of water coming down. Wherever the floats go, the sewage may go too. They have nothing to do with the ordinary displacement, 8209–23, 8452–6. Hands in a further set of diagrams. *See* Appendix A.D., illustrating the progress of the floats. The discrepancies in their progress to which Mr. Bidder called attention at the last meeting are explained partly by the influence of the wind acting on the floats in different parts of the river, especially in the crooked part between Blackwall and Woolwich. The disturbed state of the weather would have a tendency to carry the floats into slack water, and in the case of two floats traversing the same part of the river, one might be in slack water though not aground, while the other might be in the full force of the stream, 8233–84, 8443–9. He read the instructions to the men in charge of the floats, 8285–90. Sewage water contains 10 parts of chlorine in 100,000, and not 20 parts. Assuming, however, that it did, the tables he handed in would not be vitiated, they would merely require to be modified, but the difference between 10 and 20 parts is very slight, as the volume of the sewage is very much smaller than of the tidal water, 8304–14, 8474–7. He corrects an error, which was unavoidable, with regard to the length of the ebb and flood tide at Teddington. It should be 12 hours 25 minutes instead of 12 hours 13 minutes (*see* Q. 7466), 8470–2. He finds, taking the number of days required for the sewage to pass out of the river, that it only makes a difference, in some instances, in the second place, of decimals. Upon the 14th of September, at high water, taking the whole distance from Deptford to Southend, with 10 parts it would be 41·38 days, and with 20 parts it would be 41·39 days. And the same at low water you have a result of 40·97 which becomes 40·99, and so with regard to all the rest of the days, 11,758.

MR. BALDWIN LATHAM—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

POPULATION TO BE PROVIDED FOR.—Has made some calculations for the purpose of showing that the population has outgrown the accommodation which the sewers were intended to provide for, 7579. The population provided for in the north in 1858 was 2,353,900, and in the south, 1,094,600, and the western district, 553,900. This was estimated to cover the increase of population in the future. From the census of 1881, the population in the north was 2,548.999, and in the south, 1,283,448, which exceeds the estimated increased population taken in 1858 by 443,000; or nearly half a million more in the metropolis and the districts outside draining into it than the sewers were contemplated to take, 7616–39, 7647. Hands in a table which gives the population within the limits of the Registrar-General's district on the north and south of the metropolis between 1871 and 1881, and another table showing, (*a.*) the estimated prospective population from 1882 to 1901; (*b.*) the population of northern and southern London, metropolitan divisions interpolated for the 30th June of each year; and (*c.*) the prospective population at the same rate of increase until 1901, 7642, 8501. The Registrar-General's district is known as the Bills of Mortality district, and its limits correspond more nearly with the district sewered than the Metropolitan Board's district population itself does, 7642–7. Taking the increase in the population up to the present time as half a million in 20 years' time it will amount to 5,360,000, 7648–50. The rateable value has increased from 11,000,000*l.* in 1856, to 27,000,000*l.* in 1882, 7651–2.

RAINFALL TO BE PROVIDED FOR.—Has made some calculations which tend to show that the amount of rainfall which the sewers can take is really below what actually gets into them, 7580. The amount of rainfall to be dealt with is on the north 28,500,000 cubic feet, and in the south 17,250,000 in the day. The Report of 31st December 1874 also stated that a quarter of an inch of rain flowing off the area is estimated as flowing off uniformly throughout the 24 hours, or $\frac{1}{100}$th part of an inch in one hour during the maximum period of the flow of the sewage, 7652–6. The maximum flow of sewage has been calculated to be half the total volume flowing off in six hours, and the other half in the remaining 18 hours, 7657–8. One quarter of an inch a mile represents 580,800 cubic feet, and if this is divided into 28,500,000 (the quantity of rain the sewers are to carry) the area would be 49·07 square miles. Treating the south in the same way, the area would be 29·7 square miles, 7659–63. The provision made for the south is for a much smaller district than should have been provided for, but only $\frac{1}{3}$ instead of $\frac{1}{4}$ an inch of rain was taken as falling in the south (*vide* Sir Joseph Bazalgette's Report of 13th April 1856), 7664–70, 7702. The

MR. BALDWIN LATHAM—*continued.*

RAINFALL TO BE PROVIDED FOR—*continued.*

higher the district the more rain falls on it, and he would have thought it more necessary to make the larger provision for it. In a thinly populated district a smaller quantity of rain would dilute the sewage to a given point, while in a thickly populated district it would require a larger amount of rainfall to dilute it to the same extent, 7703. If the district is completely built over, then all the rain goes into the sewers, 7704–5. The conclusion drawn from this shows that a very much larger quantity of water and sewage per square mile in depth over the area is discharged at Crossness than at Barking. Out of 29·28 inches of rain falling in the south in 1875, 18·3 inches of that quantity flowed off either by flowing into the sewers or by percolation, while on the north it was only four-tenths of an inch that actually flowed off. The difference between these figures, after deducting what had been evaporated, must have come into the river at a higher point than the outfalls. The water which ought to have got out at Barking must have been liberated by the storms overflows, or else the southern sewers must have tapped the underground springs. His reason for thinking that the sewage which should go to Barking and does not, is on account of the gaugings taken some years ago at Crossness, and which were put in at length in the Mud Inquiry, 7706–9. During a dry season, as in July 1876, when these gauging observations were taken on the 12th July, no rain having fallen, it showed conclusively that out of 50 gallons per head discharged at Crossness, 30 gallons were due to sewage proper, and 20 gallons to leakage, and consequently there must be a number of days upon which there must be an overflow, 7710–8. It has been calculated that if the rain happened to come when there was the maximum period of flow the sewers could only carry away one-hundredth part of an inch per hour. The evidence given in Sir J. Bazalgette's report says, that one-quarter of an inch of rain fell only on 12½ days; but this is erroneous. Witness has taken observations at Croydon of every drop of rain that falls, and the rate at which it falls; and has an apparatus showing to what extent the sewers are affected by the rainfall. But at Croydon the conditions are more favourable, nor do the sewers fluctuate in flow so much as in London, 7762–3. In Sir J. Bazalgette's report to Parliament in 853 it was proposed by the company to provide for one-quarter of an inch of rain, but Sir J. Bazalgette said in evidence that if no more was admitted than that, the sewers would still overflow on 80 to 100 days all along the river (*see Q.Q.* 2536, 2558, and *Q.Q.* 520, 521, evidence given before the Select Committee on the Great London Drainage Bill), 7764–71. On those days the whole of the sewage mixing with the rain would not go into the river, but he is unable to say how much of it would overflow. The sewers in the higher districts were only calculated to take one two-hundredth part of an inch per hour, so whenever rain falls to a depth of one-hundredth of an inch, and there is the maximum flow of sewage flowing, there must be an overflow, but the rainfall would be very much in excess of the sewage, 7772–8. He has designed a registering rain-gauge (which has been in use since 1879), that records the time of day, the quantity, and the rate at which the rain falls. He gauged the Croydon sewers for the purpose of ascertaining the amount of spring water which leaked into the sewers whilst he carried on his rainfall observations, and from these he was able to ascertain how much any particular fall of rain affects the fluctuations in the Croydon sewers, and he hands in diagrams giving details of all his observations (*see* Appendix A., C.), 7787. The degree of fluctuation caused by rain depends on whether the maximum or minimum quantity of sewage is flowing through the sewer. The result of his observations, so far as it relates to the actual fall of rain would be a fair parallel to London, 7788–800. In 1879 the average rainfall per hour of ·066 on 132 days increased the mean flow in the Croydon sewers by 4·9 times. In 1880 the average per hour of ·075 on 135 days increased the mean flow 3·78 times, and that made it about four times as much as it was before. Had the rain fallen at that rate for 24 hours, it would have been four times the quantity of sewage, 7801–8. The Croydon sewage is more diluted with water than the London sewage on the north. On the south it is much the same as at Croydon. The quantity of water supplied at Croydon her head is 50 gallons, therefore the quantity of sewage per head of the population is greater in dry weather than in London. The

MR. BALDWIN LATHAM—*continued.*

RAINFALL TO BE PROVIDED FOR—*continued.*

average of all his observations show that if ·065 of an inch of rain falls, the mean rate of flow in the sewers is increased 4·16 times, 7809–11. The Croydon sewers are capable of carrying this off, as they have no overflow except by percolation, and all this time there must have been an overflow in London, 7812–4. There are times when the sewers have carried off twelve times the mean flow, 7815–7. He has no evidence to show how often in the year the metropolitan sewers overflow into the Thames, 7818–21. The soil of Croydon consists of chalk, gravel, London clay in some parts, and in others the Woolwich and London beds. The population is not so dense as in London, and consists of 60,000 people. The area to which he refers is three square miles, 7822–3. Reads an extract from his work on "Sanitary Engineering," with reference to the operation of rainfall on the London sewers, 8492-3.

CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES.—Occasionally sewage can be discharged from the top of the flood until about three hours afterwards. At times the tide drops so rapidly that the discharge runs for two and a half and two hours only. The reservoirs will only hold the quantity of sewage which the sewers are capable of bringing down in two to three hours, and when the sewers are running full for a longer period, the sewage must overflow into the river, 7451–2. The pumping station at Grosvenor Road is used to pump the sewage into the low-level sewer, whence it is taken by gravitation to Abbey Mills and pumped into the Barking sewer, 7453–5. Knows that it is discharged direct into the Thames at times, because it was originally intended to deodorise the western district sewage, and it was afterwards decided to carry it to Barking. When, therefore, the sewers are taking the quantity they were calculated to take at the outset, the surplus must be discharged elsewhere. Has seen the sewage running into the river day after day at Grosvenor Road, 7456-9. The figures relating to the area drained by the sewers of the metropolis have been taken from the Report of the Metropolitan Board of Works, dated 31st December 1874, 7581. The area draining into the northern high-level sewer is 10 square miles, into the middle-level sewer is 17½ square miles, into the low-level sewer 11 miles, and into the western district 14½ miles, making a total of 53 square miles. On the south the area draining into the high-level sewer is 20 square miles, and into the low-level sewer 20 square miles, making a total of 40 square miles, or a gross total of 93 square miles. At the "Mud Inquiry" totals were given as 51 and 43 square miles respectively on the north and south, but his figures he has checked by the ordnance map, 7581-5.

The following is the division of the area within the jurisdiction of the Metropolitan Board of Works:—

| | | |
|---|---|---|
| On the north— | | |
| Land in Middlesex | 49·19 | square miles. |
| Land in Kent | ·64 | ,, ,, |
| Water and Foreshore in Middlesex | 1·45 | ,, ,, |
| Water and Foreshore in Kent | ·40 | ,, ,, |
| Total | 51 68 | ,, ,, |
| On the south— | | |
| Land in Surrey | 37·34 | square miles. |
| Land in Kent | 30·70 | ,, ,, |
| Water and Foreshore in Surrey | ·99 | ,, ,, |
| Water and Foreshore in Kent | 1·39 | ,, ,, |
| Total | 70·42 | ,, ,, |

Making a grand total of 123·1 square miles.

This agrees very nearly with the Registrar General's Returns and the reports of the Metropolitan Board of Works. The difference between the amount drained and the area under their jurisdiction, viz., 24½ square miles of land, is situated principally on the south side of the river, 7586–95. The natural streams which have their source outside the metropolitan district, and which drain into it, affect the question, as the rain which flows down the stream has to be conveyed through the sewers, and adds materially to what is naturally taken by the sewers and the rainfall in the

MR. BALDWIN LATHAM—*continued.*

CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

district not included in the area of the metropolis, consisting altogether of 8·43 square miles on both sides of the river, has to pass into the sewers, 7596–601. Then in addition there are districts, such as Hornsey, Acton, Croydon, and Beckenham, which discharge their sewage as well as their rainfall into the metropolitan sewers, although this was not contemplated formerly. Rainfall was only intended to go in, but now a portion of the sewage of these places goes in, 7602–15. The Board in their calculation take six hours for the maximum flow, while the gauging of the sewers, published by the Government referees in their report in 1857, showed that half of it flowed off in eight hours instead of six. Recent experiments, however, show that half of the whole volume of sewage flows off in nine hours. The calculations are based on the southern outfall. Of the northern outfall he knows nothing, 7671–4. The sewage is perpetually coming into the sewers during the 24 hours, and it takes considerably longer for the sewage from a distance to reach the outfall than for that closer at hand. This tends to equalise the flow during the daytime. Taking the gaugings in the Mud Inquiry it is equal to deferring the sewage on the south side 11 hours. In other words, it takes the sewage from the remote districts 11 hours to reach the outfalls, while the sewage of other districts close to takes no great length of time. The minimum flow would be at about 6 a.m., and the maximum flow at 6 p.m., 7674–9. He hands in a table, which he has compiled, showing the total volume of sewage flowing in gallons or feet in the day, which if multiplied by the decimal given and divided by 100 will show the quantity of sewage flowing per minute at any hour of the day in the district. The decimal to be used for the mean quantity per minute = ·0695. This would apply all over the country to sewers where there is no leakage, 7680–1. During the maximum flow there is less room for the rainfall, 7682. By the sewage being deferred there is really more room in the sewers than had been calculated, that is to say, during what would otherwise have been the maximum period, so that if the sewage had to come down in six hours instead of nine hours, they would have been running fuller, 7682–5. The sewage discharged both at Barking at Crossness is composed partly of rain and partly of sewage proper. He has analysed the quantities which are shown in the table he hands in. The particulars go from 1875 up to the present time. He also hands in tables showing the amount of sewage flowing off at both the outfalls yearly, daily, and the quantity of sewage per head per day in gallons. These figures he obtained from the Metropolitan Board of Works, 7687–91. He has obtained the quantity of water supplied on both sides of the river by the water companies, and by deducting that from the total quantity of sewage he gets the amount of water due to rain and other causes, 7692–6. A considerable amount of water gets into the sewers from leakage and from the subsoil, which accounts for the difference of quantity per head discharged daily on the north and south sides of the river, 7697–700. Notwithstanding that on the south there is a smaller area and a smaller population to deal with, yet there is a considerably larger quantity of rain flowing off than on the north side, 7701–2. To arrive at the estimate of 30 gallons of sewage proper per head, the quantity of water supplied by the companies was ascertained, the number of houses and population given by the census returns were taken and divided one into the other giving an average 8·27 persons in a house on the north, and 7·09 persons in the south, and then dividing the quantity of water supplied by the number of persons in a house upon the north and south, the volume of water supplied per head was 30·4 gallons and 32·5 gallons respectively, which agrees with the Board's estimate of five cubic feet or 31·25 gallons per head, 7719–32, 8501. Practically 50 gallons per head, estimated on the actual population of the southern side flows off, though the actual water supplied is only 30 gallons per head. It is not necessary that this should be leakage into the Metropolitan Board of Works sewer, it may be leakage into the local district sewers, but there is the fact, 7733–5. The last table he has put in shows that the water supply on the north side gives rather over 30 gallons per head, and that the sewage and rainfall combined has not been much more than the actual water supply. In some years, in 1875 for

MR. BALDWIN LATHAM—*continued.*

CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

instance, the actual volume shown as flowing off at Barking is even less than the estimated volume of sewage, if you take it at 31·25 gallons per head. The amount that flowed off at Barking is below what was found to be a correct estimate of the sewage per head. No rainfall flowed off at Barking although 29 inches of rain fell that year. It got into the Thames by some other means, probably by the storm overflows, 7736–44. In 1876 the quantity per head is a shade more, but though there is a little less rainfall, the quantity flowing away on the north is a little more, though on the south it is a little less. It is difficult to arrive at the amount of sewage and the amount of rain flowing off separately without actual gaugings, because part of the rainfall evaporates, 7745–8. It was originally intended to treat the western area separately, but the consequence is that if the sewers are assumed to be conveying their normal quantity of sewage and rainfall, the whole of the sewage of the western district must be flowing out at a higher point as it cannot get to any point below Abbey Mills. The northern sewers are not large enough to take it, 7749–50. At page 21 of Sir J. Bazalgette's report of 22nd May 1856, it is stated that if the western district sewage is to be taken to Barking, the reservoir must hold 9,000,000 cubic feet instead of 7,000,000 cubic feet. It has been reported to contain upon one occasion 39,000,000 gallons or 6,240,000 cubic feet. In the Thames Mud Inquiry its capacity is given as 35,000,000 gallons. In the Parliamentary Report of 31st December 1873, at page 72, it is stated that in order to make provision for the sewage of the western district, the low level sewer had to be increased in size all the way to Abbey Mills beyond what it was proposed to be, and this was done, from 9 ft. to 10 ft. 3 in. in diameter. The capacity of the outfall sewer and of the Barking reservoir were not increased as reported to be necessary. Various other works were recommended, amongst them to drain the western sewage into Hammersmith Creek, and to form a covered reservoir and deodorize the western area sewage at Fulham Fields. Neither of these courses were carried out, and it is quite clear from the reports to Parliament that the northern outfall sewer was not intended to deal with the sewage of the western area, and that after it was partly completed, it was decided to take the western sewage there, for which the sewer was enlarged, but not the reservoir, 7751, 8125–6. The three outfall sewers all meet at Abbey Mills, and there are some branches which come into the northern high level sewer. The outfall sewers consist of three sewers 9 feet by 9, which are capable of discharging 33,000 cubic feet of sewage per minute, which is rather more than was stated at the Mud Inquiry. Then two 9 feet sewers which come into the reservoir have a capacity of discharging 22,000 cubic feet per minute, and the 10 feet 3 low level sewers can discharge 15,000 cubic feet a minute making 37,000 cubic feet coming in, while only 33,000 cubic feet can go out. The difference is equal to 36,000,000 gallons a day. There being more sewage in the sewers than can be discharged at the outfalls, it must find its way out at a higher point, 7752–5, 7778–86. On the south the sewer is capable of discharging 20,000 cubic feet a minute, and there is but one outfall. Taking the ordinary sewage to be eight cubic feet per head during the nine hours of maximum flow instead of six, it gives 8,955·5 cubic feet per minute of sewage. Add one quarter of an inch of rain flowing off 20 miles, and one eighth of an inch off another 20 miles, they equal together 12.075 cubic feet, which gives with the sewage a total of 21,660·5 cubic feet. The difference between this and the amount actually discharged, shows a deficiency of about 15,000,000 gallons a day. This proves conclusively that the sewers could never have carried off the quantity for which they were designed. Then rain coming in from the outside districts occupies the sewers to the exclusion of water coming in from the metropolis, so until some of that flows away by the storm overflows the sewers are gorged, 7756–60. The sewers on the south side are not competent to deal with the quantity of sewage which actually comes down, for in the tidal period of 12½ hours they do more than fill. With a population of 1,200,000 people, representing about 10,000,000 cubic feet of sewage a day, and assuming that half the total sewage flows off in nine hours, it is quite clear that a reservoir which only holds 4,000,000 cubic feet cannot hold 10 hours sewage. If,

## Mr. BALDWIN LATHAM—*continued.*

Capacity of the Drainage System as compared with the Demands upon it; Influence of this on the Storm Discharges—*continued.*

however, you increase the time of discharge and limit the period of storage, you can make the reservoir hold anything you like, 7830–2, 8336–56. The conclusion he has come to is, that on both sides of the river the reservoirs are very much too small, but immeasurably so on the north side; and all the sewage which cannot be provided for must be let out into the river at one place or another regardless of the tide, as the reservoir on the north would, if it held 39,000,000 gallons, only hold what the three sewers running full would bring down in 2·8 hours, and on the south they would fill in 3·5 hours. On the south in nine hours one half the sewage would flow into the reservoir, and more than fill it; and no doubt the sluices are opened to let it run out before the proper time, 7833–47, 8490–1. If let out on the ebb it would flow up again 12 miles above the outfall, 7848. Four hours after high water is stated to be the time when they stop the outflow, but his observations tend to show that it must be three hours, because on many occasions the water does not fall sufficiently low to enable them to empty the reservoir until that time has elapsed, 7849–50. Has no doubt from the construction of the reservoirs and the level of the sewers, they were originally made with the object of treating the sewage chemically, or in some other way, 7851–6. The bottom of the reservoir is many feet below the level of the lower lip of the sewer, and the sides of the reservoir cannot be built up because the reservoir being so low the sewage cannot be discharged fully until three hours after high water, instead as was intended on the whole of the ebb tide. If a quantity of sewage were left in the reservoir it would putrify and make the sewage more offensive than it is at present. The floor could be raised if the reservoir was on a higher level, but it would require an enlargement of the discharging capacity to obviate the possibility of the penning back of the water in the sewers, 7857–62. The gorging of the sewers would be objectionable, but so long as a sufficient fall is maintained to keep the sewer clear, it could be got over. Merely increasing the area would not diminish the defects arising from the depth of the level, 7863–5. Trinity high water is 12 ft. 5 in. above Ordnance datum. Low water is 7 ft. 6 in. below datum. The mean half tide, therefore, is 2 ft. 5½ in. above datum. He makes the mean nearly 2 ft., which agrees with diagram No. 9, in the Engineers' Reports of 6th April 1858. Mean high water is shown on the diagram at 11 ft. above datum, and mean low water at 7 ft. below datum, while mean half tide is given as 1·5 ft. He makes the mean half tide to be 2 ft. and not 1·5 as stated by Sir J. Bazalgette. The practical result is that the reservoir never can empty until half-tide level, 7866–74. Has never seen the suggestion in any of the Metropolitan Board of Works' Reports, that Thames water is used for flushing the sewers; many of the sewers are at such a level that it is utterly impossible to get water into them from the Thames for the purpose of flushing them, 8354–6, 8478–82.

## Mr. JAMES MANSERGH, Mem. Inst. C.E., F.G.S., F.M.S.

Has been in practice as a civil engineer for nearly 30 years, almost exclusively designing and carrying out works for the disposal of sewage and for water, and has advised and reported on about 200 schemes for water supply works and sewage works, 8502–5. He received a premium for his scheme for the Lower Thames Valley drainage, and has carried out drainage works in about 60 different towns, 8506–13. Was a witness for the Thames Conservancy in the Mud Inquiry, and made himself thoroughly acquainted with the river and the discharge of sewage into it, 8514–16. He was associated with Mr. Baldwin Latham in preparing evidence for this Commission, 8517–18.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—In very dry and hot weather the discharge of sewage into the river must cause a very great nuisance, and "between bridges" it is evident that a gradually increasing nuisance is threatened, because of the increase of the population having already overtaken the calculations that were made in 1858 when the scheme was laid down. The effect is that the storm overflows must come into action more frequently than was then contemplated,

## Mr. JAMES MANSERGH—*continued.*

Scientific Evidence as to the foul State of the Water in the River near the Main Outfalls—*continued.*

and the sewage gets into the river at London instead of at Crossness. He believes also that at Grosvenor Road Pumping Station the pumps pump direct into the river very frequently, 8586–93, 8639–40. In the reports of Sir J. Bazalgette in 1856, it was stated that deodorization would not be necessary if the outfalls were made as low down as Barking, 8623–4. In 1858 the gentlemen associated with Sir J. Bazalgette, viz., Messrs. Bidder and Hawksley, reported (*see page* 145) that the sewage due to the (then) population of the metropolis amounted, including some rainfall, to about 80,000,000 gallons a day, and estimated the cost of deodorizing it at 20,000*l.* per annum. From these reports he concludes it was their intention to deodorize the sewage in warm weather, and in cold weather it was to be so treated that the suspended matter would be precipitated and retained, and not sent into the river, 8625–35. In his opinion this idea should have been acted on, as the discharge of sewage in its crude untreated state into the river creates a nuisance which ought to be avoided, the more so as some of the organic matter is deposited in the river which in hot weather comes up to the surface and causes an abominable nuisance, 8636–8. At the northern outfall, when the sluices are opened at the top of the tide, and when for half an hour there is practically no current, the whole river is covered with sewage, and for a short time it causes a great nuisance to the locality, 8648. The discharge from the sewers, as shown in Table M. 3, includes all the fouled water supply which is what is technically known as sewage. The actual excreta is not the only polluting matter in the river, but kitchen water and all kinds of other things which increase the polluting element, 8925–32.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—At certain times of the tide, near the top and bottom of the tide, the velocity of the current is much less than it is in the intermediate part of it. The curve of the water at the top of the tide for an hour or two is a very flat one, and it becomes sharper as the tide begins to run down, and then it is flatter at the bottom. As the tide slackens there are, as it were, times of rest which give great opportunities for the solids to be deposited on the bed of the river. So, both at high and low water at Barking, or any other point in the river above or below, the river is to some extent a settling tank, 8641–7. A great proportion of the solids sinks to the bottom. Some of the organic matter is deposited and mixes with the argillaceous matters held in suspension in the river. It goes down with them to form the banks, and then in very hot weather that matter rises and forms patches of stinking matter which gives rise to the greatest nuisance that ever occurs, 8727–9. During the Mud Inquiry he plotted a number of cross sections to satisfy himself whether by the dredging operations on the north side the sectional area had been abnormally increased and consequently the velocity diminished. He found this to be correct, and that there was a swelling or aneurism in the river. He plotted these areas *after* the mud had been removed, but as if *the mud had not been deposited.* Then he plotted similar areas *in* the river and found that instead of an aneurism there was a constriction; the river, instead of being too large, was too small. He hands in a drawing which explains this (see Appendix X), 8730–4. The plotting of 1882 shows a slight increase over that of 1878, which proves that the cause of these accumulations is going on at present, 8735–43. These sections were plotted from the Thames Conservancy Surveys, and he took the distance of six miles each way from the middle of the Halfway Reach, as being a fair length, and not with any regard to the possible results. Had he taken five miles only, there would have been an aneurism against him and a constriction in his favour, 8744–53, 8816. The sewage discharge keeps the bank in this place. There is a constriction at Margaretness and at Barking, but Mr. More can give information on these points better than he can. The sectional area in Erith Reach is just about the normal, according to this test, 8754–67. Hands in sections of the river above and below the outfalls. The result of his survey shows that what was an aneurism has now been turned into a constriction by reason of the deposit of mud (see Appendix X) (§ preceding Q. 8815), 8949–55. The reason the section of the river showing the aneurism was not put in as evidence at the Mud Inquiry was because it was not considered expedient by the Counsel to bring it

Mr. JAMES MANSERGH—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

forward, 8734, 8822–4. He agrees with the paragraph on page 26 of the Report of the Arbitrators in the Mud Inquiry as to dredging operations having caused the banks, and altered the direction of the flow of the currents and tide, so as to produce a diminished velocity, but there is now no increase in the sectional area, but a diminution, 8900–3. He does not object to the finding of the arbitrators, but says, as they say, that a part of the banks is formed from the discharge of the sewers in consequence of the diminution in the velocity, which causes the solid matter in suspension to deposit and help to form the mud banks. Of this of course only a part is due to sewage, but it is that part which creates the nuisance in hot weather, 8914–24. Comparing his section with the state of things before the Mud Inquiry, there is undoubtedly a constriction in the river, and the increased velocity ought to scour away the banks, which it does not do, or if it does it re-deposits almost immediately, 8949–55. He now hands in a table giving the areas of the river in Halfway Reach in 1882 as compared with 1861, with regard to the alleged constriction. They extend over 1½ of a mile of the river, between 5 W. and 2 E. Cross section 5 W. is in the middle of the bank about 900 yards above the southern outfall, and 2 E. is about 1,100 yards below the southern outfall. Of these cross sections, the areas of 2 W. and 1 W. are a little larger now than they were in 1861. The rest are a little smaller. The section where there is a considerable reduction is lower down than these to which he now refers, 9065–8. His sections of 1861 are founded on the bases of the Conservators' surveys for that year, and they refer to the sections of the river before the Dagenham shoals were removed, and of course before the mud was deposited; and although the river was made too big by the dredging at Crossness Banks, it has has grown up since. During a wet year, as in 1882, the increase of the flood water would tend to increase the sectional areas, and causes them to vary at different times of the year, 9068–75.

Distribution of the Sewage in the River by the various Motions of the Water.—In conjunction with Mr. More, he has prepared a longitudinal section of the Thames from Teddington to Southend, which he hands in (*see* Appendices W. 1 to 4), 8519. To obtain this section, 133 cross-sections were made, and the cubic capacity of the river has been obtained by this means, 8520–1. Hands in a table which gives the capacity of the River Thames as shown on longitudinal sections marked respectively A′, A, B, B′, 8522–4, 8539–63. He has marked this Table of capacity M. 1., 8573. The two first were taken at spring tides, viz., on the 1st and 30th of October 1882. On the latter occasion the river was in flood. The other two were neap tides, 8525–31. There are two colours on the chart or section, light blue and dark blue. The line dividing the two colours shows the surface of the water from Southend to Teddington, at the moment of low-water at Southend, and the upper line shows the surface of the water from Teddington to Southend at the time of the following high-water at Southend. These lines may be called synchronous lines. The dark blue colour shows the quantity of water which entered the river from above Teddington, and from the tributaries between Teddington and Southend, as well as from the sea, between low and high-water. The light blue colour represents the water in the river at Southend at low-water, 8532–38. There was a difference in the quantity of water at high-water in the river on the 6th October of one-twelfth more than on the 4th November 1882, although on the latter day there was 5½ times as much land water coming in. This was due to the fact that the wind on the 6th October blew from the east, which tended to keep both the high and low-water up; whereas on the 4th November it blew from the south or west, which would have a contrary effect, 8564–70. The water impelled into the river from the sea upon a high spring tide is, roughly speaking, twice as much as on a low neap tide. It tends to raise low-water from Teddington to London Bridge, but it does not affect anything much below that point. It is the tidal wave which fixes the height of the tide, though modified by the wind, 8571–73. The heights upon Roberts's tide tables are the calculated heights, 8576–7. Hands in a longitudinal section of the river Thames, showing the sectional areas between Teddington and Southend. On the section a line is put which shows the mean line between absolute high-water and low-water heights. It has been deduced from

Mr. JAMES MANSERGH—*continued.*

Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

a number of observations of the self-recording gauges at various places on the river, 8574–85. This table is marked M. 2., 8581. The progress of the sewage to the sea has been worked out from the two factors, viz., the displacement by upland water, and the displacement by mixing with the sea water, and not from the float experiments. Unless taken in conjunction with the chlorine tests, they would practically give no information as to the progress, 8649–51. The influx of the tide diminishes the area available for the passage of the land water, and therefore increases its velocity. If the upland water flowed into a lake or tideless sea, and the channel of the river had the same slope and sectional area throughout, the daily progress down the river would be the same; but the progress would be diminished if the sectional area was increased in an inverse ratio to the increase of that area, and vice versâ, 8652–63, 8676–81. The mixing action takes place whenever fresh and salt water come together, and it is facilitated by eddies, currents, winds, and the screws of steamers, 8664–7. He shows a diagram explanatory of the way in which molecules of fresh water are surrounded by sea water as they move up and down the river, and are therefore forced down to the river by their increased size, as they cannot occupy the same position they did when fresh water only, 8668–72. Whoever invented the chlorine tests, in his opinion, has done great service, and he has adopted them. They give a mode of measuring the mode of progression which was never thought of before, 8673–5. He has prepared some other tables marked M. 3a, M. 3b, M. 3c, and M. 3d, which he hands in, 8682. The object in preparing these tables was to make out the time in which the land water with the sewage in it would progress to the sea, and he has worked upon somewhat different lines to Mr. Baldwin Latham for the purpose of explaining it in a clear way, and of checking their relative results, 8683. The two days, viz., 14th of September and 30th November, werechosen, as on the first day there was a comparatively small quantity of land water, and on the second day there was a comparatively large quantity coming down, 8684–5. Taking Crossness as the middle point, because there are 30 miles above and 30 miles below, he has divided the river into 12 parts of five miles each, six on each side of Crossness. The tables give the divisions of the river, the chlorine found by analysis, the contents of the river, the percentage of sea water (from chlorine), the quantity of sea water, the percentage of upland water, including sewage (from chlorine), the quantity of upland water and sewage, the quantity of upland water at each division (by gaugings), &c., &c., in each division, and the time taken to progress through each division, and the total time from Teddington to Crossness, and Crossness to Southend. The measured quantity of water of upland water entering the river in each division is calculated as coming in at the upper end of that division; the sewage discharged at Barking is calculated at 14,760,000 cubic feet, and at Crossness 11,240,000 cubic feet in 24 hours. Upland water is taken as containing 1·7 parts of chlorine, sewage 10 parts of chlorine, and sea water 1,961 parts of chlorine per 100,000 parts. It has been assumed for the purpose of calculation, *but not admitted*, that there is no sewage in the river above Barking, 8684–8715. The results obtained from these tables agree almost exactly with Mr. Baldwin Latham's calculations, 8717. A big flood cleans the river and accelerates the progress to the sea, so in very hot weather, when there is little water coming down, the rate of progress is retarded, 8718. There is no doubt that there is sewage above Barking and Crossness, but he is unable to satisfy himself sufficiently as to the *measurement*. He is dealing only with the volume of sewage discharged from the outfalls, and leaves it for chemists to say whether it maintains its polluting and nuisance-creating character all the way down the river, 8725–6. In his tables he has derived the percentage of sea water (from chlorine) and the percentage of upland water, including sewage in the way that Mr. Baldwin Latham explained, and he has used the same formula $\frac{A - B}{A - C}$. A = sea water, B = river water, and C = the chlorine in the sample found, which is 4·7 in the fifth division above Crossness. The accuracy of the tables depends on the assumption that the quantity of chlorine in the sewage, fresh, and sea water are correct; but below Crossness, if they are not correct, it would have very little effect

## Mr. JAMES MANSERGH—*continued.*

### Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

indeed, 8768–88, 8936–39. If the sewage contained 20 parts of chlorine instead of 10 parts, it would make a correction and reduce the sectional areas due to sewage and water; but it would be of very little importance down to Crossness, and below Crossness would make very little difference in diminishing the rate of progress, 8789–91. The tables give the rate of progress to the sea, but the means of the tables must be taken, not each table separately, 8792–8802. At any given ebb tide half the content of the water between Barking and Southend goes down the river towards the sea, but does not actually *go out to sea*, because a proportion of it flows back with the following tide, though mixed with water which has been moving backwards and forwards for some time probably, 8803–14, 8854–70, 8942–44. He hands in diagrams on which sections of the river are plotted, showing the line of high-water up and down the river on the days mentioned in his Tables of Capacity. The synchronous lines of high-water, low-water, mean flood, and mean ebb, at Southend and Barking, are represented. (*See* Appendix Y.) The blue line, which represents the normal river, is a straight line, as the curve of the sectional area proportionate to the water above it is so flat as to be impossible to show it as a curve, 8815–21. The basis of the tables M. 3, &c., is founded on the assumption that the upland water and sewage are in the proportion that the quantity of water gauged as coming over Teddington Weir and other tributaries bears to the quantity of sewage discharged from the outfalls on any given day, and also assuming that sea water contains 1,961 parts of chlorine, 8825–42. If on the 30th November 1882 the sea water at Southend contained only 1,785 parts of chlorine, it would be due to the quantity of land water which had come down during the past few days, and diluted the sea water. Produces a paper showing on what his analysis was based, which is the same as Professor Way's, 8843–46. The upland water would affect the salt water at Margate, but not over the whole of the estuary. Very possibly 12 per cent. of the sea at Margate is fresh water, 8847–53. In calculating the rate of progress to the sea, Southend was fixed on as being the end of the river in order to avoid any complication with the Medway. Although the Medway water is brought up by the tide, it makes very little difference in the chlorine tests as regards the lower portion of the river, and at Barking and Crossness the Medway water would not affect the question, as the tidal oscillation would not bring the water up so far in one tide. Any excess of chlorine at Westminster would be accounted for by the presence of water from below Southend, 8871–85. The tables do not take any account of the extent to which the sewage has been destroyed by decomposition. They merely represent the quantity which comes down through the sewers. Sewage put into running water is destroyed to some extent, but how far he prefers to leave to the decision of chemists. Running water purifies sewage to some extent, but he believes a good deal of the solid matter in suspension is deposited in the bed of the river, 8891–99. He is perfectly satisfied that the figures in his M. 2 table are accurate, and that no mistake took place in taking the figures for one section from the wrong gauge. He has no objection to produce his cross-sections, which are 134 in number, 8904–13. As regards the results of the oscillation of the sewage, the lower reaches of the river are not so important as the 15 miles below Crossness, 8933–35. He has re-checked his formula for working out the percentage of chlorine in sewage, and the supposed error was due to the fact that he had not worked out the percentages beyond one place of decimals. The accuracy of his figures is proved by carrying the figures further. Thus,

$$\frac{1{,}961 - 4{\cdot}7}{1{,}961 - 1{\cdot}7} = \frac{1{,}956{\cdot}3}{1{,}959{\cdot}3} = {\cdot}9984688 =$$ the proportion of upland water. Multiplying this by 1·7, which is the amount of chlorine in upland water, it gives 1·6973969. Deduct upland water from 1 the remainder is ·0015312, which, multiplied by 1,961 (the chlorine in sea water), gives 3·0026832, and that added to 1·6973969 makes a total of 4·7000801, which is the exact figure in the first column of the table, 8936–9. There is a difference between the sea water at Margate as compared with the sea water at Southend. At high-water there is a little more chlorine at Southend, and at low-water there is considerably less than at Margate, 8940–1. The float experiments cannot be relied on for actual calculation, but only show the range of a certain part of the water, floating up and down and, given that range of the tide, no great volume of the Medway water can get very far up the river as fresh water. Above Southend it must be very largely diluted, 8945–8.

## MR. CHARLES JAMES MORE, Mem. Inst. C.E.

Engineer to the Conservators of the River Thames.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—In the summer time there is a most offensive smell in the reaches from the river, which he has noticed even at Woolwich. It is especially bad between Woolwich and Erith. It is horrible when the mud is stirred up by a steamboat. In the winter there is no smell, 9010–12, 9049–50. He has frequently seen the sewage running out from the northern outfall in a small stream until low water, and it would of course be carried up on the flood, 9013–15.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He has been constantly on the river between London and Gravesend during the last 13 years, and has personally surveyed the river from London Bridge down to the lower end of Long Reach, 8961–6. Accumulations of mud are found in various places, extending in some parts right across the bed of the river, and in others only in bights. He hands in three plans, showing exactly the present condition of the bed of the river and the deposits of mud, gravel, clay, and peat (*see* Appendices Z 1, 2, and 3.), 8967–8. The mud varies in depth from six or seven inches to eight or ten feet, and it is evident it has been brought there, as the bed of the river was originally gravel, 8969–70. In Bugsby's Reach there is very little mud, except on the foreshore, on both sides until you get to the lower end of it. The amount varies according to the season and the rainfall. Woolwich Reach is very muddy indeed, and it extends almost across the river. The depth of mud here varies year by year from one to two feet. Galleons Reach is very muddy all along the Bight on the Essex shore. Near the Beckton gasworks there is a great depth of mud, and it extends as far as Barking Creek, round the lower end of the bight. It is six or eight feet deep, 8971–9. From Margaretness on the north to Crossness on the south, and from False Point to opposite Dagenham, is very muddy nearly across the river, and varies slightly only. Halfway Reach is very muddy, especially on the south side where the southern outfalls are. It is nine or ten feet deep far out into the river, and is extending further down the reach. There is mud also off the north side opposite Jenningtree Point. From here all the way down to Erith on the Kentish side is muddy, and it increases in the lower end of the reach. Off Erith it is six or seven feet deep and extends about one third of the way across the river. It has increased lately. There is not much mud round Erith Rands until you reach Crayfordness, when there is mud down the centre of Long Reach, 8980–96. Between high and low water mark there is a great deal of mud all the way down past Gravesend, 8997. He remembers places which were quite clean, and you could land from a boat without difficulty, which are now covered with three to four feet of mud. The locality of the deposits does not change much, but the depth varies slightly, and the area increases year by year, especially in the neighbourhood of the outfalls, 8998–9001. The mud is very black and shiny, and of a more offensive character near the outfalls than elsewhere in the reaches. It is very much complained of by the men employed by the Conservators to raise anchors and wrecks It is blacker than mud found further away. Down as far as Sea Reach this offensive mud is found, 9002–6. The survey of 1861 does not contain the soundings of the mud, so it cannot be compared with his chart which he has handed in, but he can from his own observation speak to the offensive character of this mud, 9007–10. He has prepared a plan of the bed of the river for the years 1877, 1878, 1879, and 1882. The latter is of Barking and Halfway Reach. Has also prepared sections of the river, which he hands in. (*See* Appendix A.A.) They go right across the river, and are for the years 1832, 1861, and 1882, 9017–23. They show a good deal of dredging between the years 1832 and 1861 in Erith Reach and at the Rands, and between 1832 and 1882 they show a very large

## Mr. CHARLES JAMES MORE—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

accumulation of mud on the south side, which has taken place principally between 1861 and 1882, 9024–8. Contemporaneously with the growth of the mud banks at Barking, Margaretness, and Halfway Reach, dredging operations have been going on, as was the case at the time of the Mud Inquiry. The result of the artificial deepening of the river on one side has been to cause the mud to silt up on the other side, and so increase the sectional area. Dredging was carried on to a certain extent near Erith between 1861 and 1882, 9037–48, 9051–4. No dredging has been done opposite the southern outfall since the date of the Mud Inquiry, and the accumulation is still going on. Dredging generally has the effect of increasing the sectional area. In recent years dredging has taken place principally in Erith Reach, 9055–7. Is unable to say without further examination of the sections whether the sectional area of the river in Erith, Barking, and Halfway Reaches has largely increased, as compared with 1861, but it may be accepted that the accumulation of mud has, apart from the dredging, diminished the area. 9058–64. The cross-sections were taken about September last year. (This refers to the sections which Mr. Mansergh put in, but could not give the date when they were taken in 1882), 9076–9. He now hands in two tables, one giving the area of cross sections of the Thames at Erith, and the other showing the increase or decrease in the areas at Erith between 1832, 1861, and 1882 (*see* Q. 9062.), 9079*a*–83. The figures quoted by Captain Calver at the Mud Inquiry on the increased sectional area of the river from Barking to Erith, between 1861 and 1879, were not compiled by witness. The materials were supplied from the Thames Conservancy office to Captain Calver, but the calculations were made outside the office, 9084–98, 9101–3. Between 1879 and 1881 a number of shoals were removed from the river near the outfalls by dredging, but not at Dagenham after 1879. There were extensive dredgings though in Erith Reach, 9099–9100. There is an increase in the sectional area opposite Erith town causeway between 1861 and 1882, but all the others show a decrease. There has been dredging in that reach, no doubt, which would account for the increase, 9104–9.

Set of the Tide.—He took no part in the float experiments recently, but he has taken float observations some time ago. They were taken for the purpose of observing the set of the currents, and not to ascertain the distance an object would float with the tide, 9029–31. In the crooked parts of the river above Long Reach the flow of the stream is very variable, much more so than in the lower reaches. There are eddies of different velocity round the points and upon different sides of the reaches, and at different points of the reaches, which would fully account for two floats in the same reach making different journeys. If one got into an eddy, it would remain there a considerable time. Objects in the reaches would be more subject to the influence arising from the shape of the reaches than objects outside the reaches, 9032–6.

## Mr. R. W. PEREGRINE BIRCH.

Member of the Institution of Civil Engineers.

Scientific Evidence as to the foul State of the Water in the River near the Main Outfalls.—While making the float experiments, the river was not at all favourable to the development of any nuisance from the sewage, as from the middle of September to the early part of November the weather was cold, 9286. The surface of the river must be very striking to anybody constantly passing up and down the river. He has drifted up on a steamer and seen the most undisguised sewage on the surface, as high up as Blackwall and down to Purfleet, nearly every day, floating either in the currents or lying on the sides, marking the distinction between the slack places and the stream. Standing on the sponsons of the tug, he has received the spray in his face, which reminded him of the sewage most distinctly. This he has noticed as far down as Erith, 9287–9. The temperature of the water was considerably lower than the summer temperature, 9289–90.

Discharge from the Storm Overflow Outlets.—On the 22nd October 1882, when in Deptford Creek after a considerable fall of rain, there was an extensive overflow from the storm outlets, and he saw more solid

## Mr. R. W. PEREGRINE BIRCH—*continued.*

Discharge from the Storm Overflow Outlets—*continued.*

sewage floating on the surface of the water than he ever saw floating on the surface of any water in his life. By solid sewage he means human excreta. It must be a serious disadvantage to people having property in the Creek. It was about half ebb tide, and the sewage was floating out of the creek with the stream. It certainly did not come from the main outfalls, 9292–9310.

Distribution of the Sewage in the River by the various Motions of the Water.—He served his time with Mr. Abernethy, and so gained a considerable experience in tidal matters. He has also devoted considerable attention to questions connected with the disposal of sewage, 9110–13. He was engaged by the Port Sanitary Authority to make a series of tidal experiments in 1882, and on the 17th September he commenced operations between Barking and Southend on the north, and Northfleet and the Isle of Grain on the south side of the river. He also made arrangements for the daily gauging of all the streams between those points. To effectually superintend the operations he took up his quarters on the steam tug "Toby," and he and his assistants were at work for 18 to 20 hours a day during the whole time, 9114–24, 9356–61. Six floats were put into the river at different stations, and were watched day and night, and he believes the experiments were fairly conducted, and has no reason to believe that the floats were tampered with, 9125–36. The floats were left to take their own course, except when there was danger of their running aground, when the men had orders to pull them out into the stream, and the results are no criterion of the progress of sewage to the sea. They were merely tidal experiments, 9137–40. The floats upon a flood tide are less affected by lateral influences, such as wind and irregularity of course, than the floats upon a neap tide. It is due to the greater velocity of the flood tide over the ebb. The land water comes down with the ebb in greater quantities than that which goes up with the flood, but the time it takes to come down is increased in a much larger degree than the volume is increased, 9141. He has made a calculation, which he hands in, showing that the velocity of the flood tide at Barking is greater than that of the ebb tide by 20 per cent., 9141–3. This would account for the longer distance traversed by the floats on the flood than on the ebb, and for their keeping a better course. It tends to show also that the flood would have the effect of carrying up any deposit from the mouth of the outfall, and depositing it higher up, 9144–8. The agent which principally effects the scouring of the river is the fresh water from the river, and the new water from the sea, not that water which is oscillating backwards and forwards, 9149–51. The quantity of sewage leaving the river depends upon the quantity of fresh water coming in, which is dependent on the up-country rains, and the character of tides at the time, 9152–3. He has worked out in diagrams the particulars of the three days, the 14th and 22nd September, and the 30th November 1882, which Mr. Latham and Mr. Mansergh worked out in tables. These diagrams he hands in. (*See* Appendices A. B., 1, 2, and 3.) Although he has worked it out in a different way, the results are practically the same, 9154–6, 9222–9, 9337–47. On the 14th September there was a spring tide and the flow at Teddington Weir was 8,332 cubic feet per minute. On the 22nd of September there was a neap tide, and the flow at Teddington Weir was 122,451 cubic feet per minute. On the 30th November the tide was between spring and neap, and the flow was 476,345 cubic feet. There was a very great flood on that day, 9157–61. The first diagram shows the respective quantities of sea water, inland water, and sewage in the various reaches of the Thames on the 14th September from Barking to Southend, and it also shows that the northern sewage of the 16th August, mixed with the Teddington water of the 4th August, reaches Southend on the 14th of September, taking 30 days to travel from Barking to Southend. Every day's upland water and sewage which affects this diagram is localized longitudinally by the red lines across the white column, and its volume shown on each block in red figures. Each of these blocks is supposed to contain 26,000,000 cubic feet of sewage. The day upon which each block of water came over Teddington Weir is also shown. The same details are shown on the other diagrams, 9162–8, 9183–9206, 9235–7, 9315–25. At Southend the white column is smaller because there is less fresh water than there is higher up, but it travels faster. He adds that the diagram is not a true plan, but a

## W. PEREGRINE BIRCH—*continued.*

### Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

developed plan. It represents what width the river would be if it were one foot deep all over, 9169–72, 9221. He attributes the greater rapidity of the column of water at Southend to the influx of sea water, which reduces the cross sectional area. If the area is increased, the velocity is reduced, and vice versâ. But for the action of the sea water, the velocity at Southend would be be a twelfth of the velocity at Barking. As it is, it is a little faster than at Barking, 9173–7, 9214–20, 9231–4. All this is founded on the salt test, and it is absurd to say that 1961 parts of chlorine is the wrong standard, as at Margate 1950 grains have been found in the salt, and he has no doubt thet the normal quantity in the middle of the estuary would be 1960 grains in 100,000. To put it as low as 1700, would be absurd, 9178–81, 9258. He omitted to explain that in the diagram the line upon the upper side of the dotted line shows the limit of the high water capacity, the lowest hard blue line shows the low water capacity, and the two outer dotted lines and the two inner dotted lines show respectively the limits of the mean river capacity and the mean fresh water column. As the limits of the mean fresh water column are wonderfully near the limits of the high water column on the one side, and the limits of the low water column on the other, he considers he is quite justified in taking the mean as the average column of the day, 9182. To ascertain the progress to the sea, the velocity is obtained from the cross sectional area of the column. Then dividing the day's supply in cubic feet by the sectional area in square feet, the day's progress to the sea is ascertained with accuracy, that is, if you could see the column, which is impossible. Salt tests are therefore resorted to, and by ascertaining the amount of chlorine you learn the amount of salt there is in the water, 9207–13. Taking the second diagram for the 22nd September, there were 32 days' flow of inland water and sewage between Barking and Southend, and on the 30th November, when the river was in flood, there were only 11¾ days' flow of inland water and sewage between these two points, 9235–47. On the 14th September the sewage would be diluted by eight times its bulk, on the 22nd September by 14 times its bulk, and on the 30th November by 30 times it bulk of water, 9248. Similar details are given as regards Greenhithe, Gravesend, and Southend, 9251–7. This is shown on the diagrams, and also on the tables put in by Mr. Latham and Mr. Mansergh, 9249–50. If the quantity of chlorine in the sewage was taken to be 20 parts instead of 10 parts in 100,000 parts, it would make no difference whatever in his calculations, as it would increase the quantity of chlorine in the upland water by $\frac{1}{1959}$th part only, and would make only 20 minutes difference in a month in the period taken by the sewage to travel from Barking to Southend, 9258–62, 9326, 9333–34. The water from the Medway cannot enter the Thames to any appreciable extent because the Medway water has to escape to the sea in exactly the same way the Thames water gets out. Now at Barking the water which did not come from the Thames is equal to one-fiftieth part of the sea water at Southend, and as the Thames is 10 times the size of the Medway, it follows that only one five-hundredth part of the water at Barking could be Medway water under the most favourable circumstances, and he does not profess that his calculations are nearer to accuracy than one five-hundredth part, therefore he is quite satisfied if there is no greater error, and the mixture of Medway water would not therefore be appreciable at Barking. It is the greater specific gravity of sea water which causes it to penetrate the fresh water, and it is forced up by the rise of the tidal column. If the sea water and fresh water were of exactly the same specific gravity, the effect of the tidal column coming in would be simply to raise the fresh water as against the salt, 9263–80. The diagram he handed in, showing how the fresh water is got rid of at the mouth of the Thames, applies equally to the Medway, and the difference of specific gravity acts quite as strongly on the Medway water as it does upon that of the Thames, 9281–3. He has not built any argument upon the salt survey with regard to the sewage pollution above Barking, but has applied this process simply to the river between Barking and Southend; but there can be no doubt that the sewage discharged on the last of the ebb must go up with the flood nearly the whole range of the tide, which is 11 or 12 miles, 9284–5. His diagram is based upon the supposition that all sewage passes from Barking downwards to the sea, and any water that has

## Mr. R. W. PEREGRINE BIRCH—*continued.*

### Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

gone through the London sewers he calls sewage. The diagram does not depend at all upon any solid matter at the bottom of the river, but only deals with the column of water coming from the sewers. The only thing that bears upon the deposit at all is that the flood tide is stronger than the ebb, 9300–5. Chloride of sodium, being a soluble matter, would, if it existed in any suspended matter, be dissolved out and washed down by the tide, 9313–14. Chloride of sodium is, he knows, taken as a test of the pollution of pure water by sewage, but not in sea water. Not being a chemist, he does not understand chemical analysis, and his calculations do not therefore refer to pollution, but to the mixing action only, 9327–36. In comparing Mr. Mansergh's tables with his diagram for the 14th September, the discrepancy between the two sectional areas at Crossness may be due to the fact that the same points have not been taken by each, and also there may be an error in taking the dimensions of the column of water at the Barking end synchronously at the different points, 9348–55. Any complaints which may be brought against the men who had charge of the floats he will inquire into on receiving the particulars of the charges, 9362–7. Samples of water for the purpose of ascertaining the amount of chlorine in the river were taken, he believes, at St. Paul's Pier, Deptford, Barking, Crossness, Erith, Gravesend, and Southend, at high and low water on the 14th and 22nd September, and on the 30th November, 9368–73. The discrepancy referred to at Questions 9348–55 he now explains. It is due to the intermediate divisions being interpolated by the eye, and not accurately interpolated. If you get half a day out upon each side, it makes a difference of an addition or a deduction equal to a day's flow, 9779-81*a*. His distances cover an area of 29½ miles, while Mr. Mansergh's area is composed of six divisions of five miles each, and this causes an error in the totals of about five or six per cent. When he found that it was in favour of the Metropolitan Board of Works, he did not go further into the question, as he would have done had it been against them. It gives in fact a quicker progress to the sea of one day and a half, 9782–90. He has made inquiry of the men in charge of the floats, and supplies the names which were applied for (*see* Questions 9362–7). The complaints brought against these men were handed to him since the last meeting of the Commission, and he has received denials from the men that they had done wrong in any way. During the time the experiments were going on, he received no information of any misfeasance on the part of the men, and he had no reason to be dissatisfied with them, 9790–9804.

## PROFESSOR WILLIAM CAWTHORNE UNWIN.

Member of the Institution of Civil Engineers, and Professor of Hydraulic and Mechanical Engineering at the Royal Indian Engineering College, Cooper's Hill.

Distribution of the Sewage in the River by the Various Motions of the Water.—There are only two ways in which the volume of sewage discharged into the river can disappear from the river and so escape, being considered a question of hydraulics. Part may escape by decomposition into gas, but that volume would be very small; and part may be deposited upon the bed of the river, and would no longer form part of the flow of the river; but there are no means of ascertaining what proportion of sewage disappears in that way. He supposes it is then still in the river, and still liable to do injury to it, 9373–7. The portion that remains in the river he deals with for the purpose of representing the sewage, and what goes into the river he considers, for his examination, as remaining in the river, 9378, 9380, 9722–9, 9769–70. The extent to which the sewage in the river is noxious or innocuous he leaves entirely to chemists and biologists, 9379. In ascertaining the principles which control the movement in a non-tidal river, the quantity of water between two sections must be constant, so that the quantity of water flowing in at one end is equal to the quantity flowing out at the other. But if the river carries different materials, such as river water, sea water, and sewage, then the quantities of each flowing in must be equal to the quantities of each flowing out, 9380–4. In a tidal river the volume between any two sections is constantly changing with the height of the tide; but if the alteration from day to day of the range of the tide be neglected, then at

PROFESSOR W. C. UNWIN—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

corresponding phases of the tide the volume between two sections is the same, 9385–7. The down stream displacement at every section in the river must therefore be, in each tide, the volume of the upland water divided by the area of the section, and the displacement due to the upland water alone will vary with the area of the section, 9388–91. Local currents and other differential motions of different portions of the river cause some slight modification of the displacement, which produces the mixing action of the sea water with the river water. So also the sewage may sometimes be carried by the range of the tide higher up or lower down than it would ordinarily be taken, displacing an equal quantity of upland water, and this must be repeated upon every tide, 9388–9402. The same remarks would apply equally in a straight reach, like the Dee at Chester, because in the straightest reach the central or surface portions move about 15 per cent. faster than the mean, and about 25 per cent. faster than the bottom. It is a principle applicable to all streams, though it is rather difficult to say whether the local causes would apply to a winding river like the Thames in an equal or greater degree than to a straight reach. Probably there would be more local currents in a winding stream, 9403–8. According to this theory the foul water from Crossness might work up to Teddington or to a point not more distant from Teddington than the upland water displacement in the period of a tide. Close up to Teddington it would be driven back by the upland water, 9409–10. In the part of the river below Crossness the effect of the mixing action is to make the Crossness water go down stream quicker than it otherwise would, and that water which goes down is balanced by the sea-water which comes up to Crossness. So also when any foul water (that is, the Crossness water) gets higher up than the mean, a similar quantity of pure water goes lower down than the mean to fill its place. In a river consisting of different materials this displacement has the effect of distributing all those materials over the whole length of the river; but in a river consisting entirely of fresh water it would have no practical effect, 9411–15. During the flow of a spring tide about 24,400,000,000 cubic feet of sea-water flow into the river at Southend and mix with the foul water up stream, carrying part of it back to the sea. If, however, the Thames was an arm of the sea, having no supply of upland water, then, apart from the mixing action, it would gradually fill up with sewage; but in consequence of the mixing action a portion of the sewage would still travel out to the sea at a considerable pace at each tide; but he is unable to say in what proportion to its present pace, 9416–21. On account of these influences, where sea-water has passed to a higher point than where it started from, the mixture must go to the tidal limit, except the distance occupied by the quantity of upland water that comes in during one ebb. Supposing there was no upland water, it must still go to the top, and even in a narrow estuary (so to speak) the effect would be the same. He does not speak of the quantity; the curve may be asymptotic, or it may become excessively small, 9422–5. The extent to which sewage would come up the river is a matter of degree according to his theory, and would depend partly on the position of the outfalls, and matters of that kind. As it is, part of the sewage discharged from the outfalls flows back through the whole range of the metropolitan district, which was contrary to the intention of Parliament when passing the Act, 9426–32. He has prepared some diagrams and tables from data supplied to him of three tides during which observations were taken. The days were September 14th and 22nd, and November 30th, 1882. From Professor Way he received chlorine analyses of the water at Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, Barking, Crossness, Erith, Gravesend, and Southend, at high and low water. From Mr. Mansergh he received computed sections of the river at high and low water at these ten places; and from Mr. Baldwin Latham he received gaugings of the water coming over Teddington Weir, and the water coming into the river from the tributary streams. These diagrams and 13 tables he hands in (*see* Appendix A.E., 1 to 21), 9433–42, 9627–33. Diagram No. 1 represents the horizontal oscillation of the tide for two tides, a spring tide and a neap tide, and he ascertained this by computing the volumes of water in the river above each of the sections at high and low water. For example, in Table 2, on the 14th September there were 10,474 cubic feet above St. Paul's Pier at high water, and 10,210 cubic feet at North Woolwich at low water, and he says that the horizontal oscillation of the tide at those places was from North Woolwich to St. Paul's Pier, because the water which occupied the space above St. Paul's Pier at high tide just filled the river down to North Woolwich at low tide. Then the resultant oscillation of any particle would be that distance, for, if any particles went more, others must have gone less. The mean motion must have been through that distance. He is now taking the tidal oscillation only, and will consider the displacement due to the upland water separately as more convenient, though the diagram has been calculated with it, 9443–50, 9452–4. He explains the diagram to the Commission, showing what the different lines represent, 9451, 9455–6. On Table 3 the horizontal oscillations are given in miles measured off the diagram, and his tidal oscillations are shorter than those observed by Mr. Baldwin Latham, being rather less than 11 miles in a spring tide and 7 miles in a neap tide, the difference being due to the fact that Mr. Latham's floats gave the motion of the central and surface parts of the water, and not exactly the mean motion of the water. The diagram is not affected in the least by any disturbance due to differential causes, such as eddies, &c., 9457–62. On referring to Table 3, it will be seen that the alteration of the height of the tide between the 14th and 22nd September gives a considerable displacement, which is also shown by Mr. Latham's floats. This was due to the tides decreasing from spring tides to neap tides, which caused a displacement up stream varying from 3,000 horizontal feet at Chiswick to 12,000 horizontal feet at Southend. When the tides increased from neap to spring tides there would be a corresponding displacement up stream, 9463–7. The column giving "the increase of the low-water volume" he inserted in the table to show that it is one of the causes that carries water up stream. The scale of the first half of Diagram 1 is a vertical scale, ten times as great as the latter half, and the figures on the horizontal lines represent distances in feet, 9468–71.

Diagram 2 represents the volume of fresh water flowing at each section of the river, including sewage. This includes the flow from Teddington, from the tributaries, and from the sewers. The principal importance of this diagram is to show how very small an influence the tributaries have, except the two affluents at Barking and Crossness, where the flow is increased considerably, 9472–6. The tributaries flowing in at different points of the river are shown by means of steps at the nearest place to where they enter the river, and the increased volume of sewage flowing at Barking on the 30th November is due to the influx of several tributaries which enter the Thames between Deptford and Barking, the Lea especially, which was flowing largely on that day. Generally, but not always, it follows that when the tributaries are in flood the Thames is in flood also, 9477–84, 9561–2, 9751–3. Diagram 3 shows the amount of displacement down stream at each section due to the upland water alone, neglecting the tidal oscillation. It is arrived at by dividing the volumes in diagram 2 by the areas of the sections. The Diagram is calculated for the 14th September alone, and it was done simply to show the way in which the displacement due to the upland water is diminished as you go down stream. The scale gives the miles per tide, and between Deptford and Erith the mean displacement is about $\frac{5}{8}$ths of a mile per tide, while at Gravesend it goes down to ·2 per tide, or $\frac{2}{3}$ths of a mile a day, 9485–98. The water coming over Teddington Weir on that day was about the average quantity. If it should be less than the average, then the displacement would be less, and *vice versâ*. The formula for calculating the amount of displacement owing to the water coming over is "the "displacement is directly as the volume," 9499–9502, 9700–21, 9766–8. The figures relating to the sewage flow he obtained from page 17 of Mr. Latham's report for 1881, where it is given as 13,603,000 cubic feet per tide, or 26,000,000 cubic feet per day, 9503–4. If the progress of the floats gave a mean down stream travel, they would agree with his diagram No. 5, but the down stream travel of Mr. Latham's floats is very much smaller than it would be according to this diagram, because they were kept to the middle of the stream, and were too short to reach down into those layers of water which move slowest. They therefore had a greater motion than the mean motion, and represent the motion

PROFESSOR W. C. UNWIN—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

of those parts of the water which are nearest towards the centre and towards the top, 9505–9, 9625–6. In all streams the surface has the greater motion, and the motion of the centre is greater than that of the sides. The motion in the centre and at the surface combined would therefore be considerably greater than the mean motion of the water, 9510–12. A slight alteration in the velocity either in the up stream or down stream travel will make a great alteration in the tidal displacement. About 4 per cent. alteration of velocity up stream will diminish the down stream displacement to nothing, while the same alteration in the down stream velocity would double the down stream displacement. To explain Mr. Latham's results, it is necessary to find out whether there was possibly such an alteration in the velocity of the float during its 12 mile travel up or down stream, 9513–14. He thinks it is possible that there is quite 4 per cent. more central and surface velocity during the flow of the tide than during the ebb, 9515. In the crooked parts of the river the whole stream twists upon itself, and the ordinary ratio of the velocity of the central and of the surface water to the mean velocity is very considerably altered. It seems probable that in these parts of the river the travel of the floats would be different from what it would be in the straighter portions of the river, which, if it is true, would account for the discrepancies in the progress of the floats, 9516–19. If there was no mixing action the travel of the sewage would be identical with the travel of the floats. As it is, owing to the mixing action, the sewage travels down quicker than the floats, because, in addition to the upland water which pushes it down, it is also pushed down by the sea-water which is left in the low-water volume after each tide, 9520. Diagram No. 4 represents the curves of saltness for three tides from data supplied to him by Professor Way. The vertical scale shows the number of parts of chlorine in 100,000 parts, and he has taken the quantity of chlorine in sea-water as 1,961 parts in 100,000. On the 14th September, at high water, the water at Erith was half as salt as pure sea-water, 9521–31. His reason for plotting this diagram was to show how greatly the quantity of upland water affects the position of the chlorine lines. Any increase in the upland water drives down the chlorine lines very much. The explanation of the saltness of the water on the surface being very slightly less than that taken at a considerable depth is due probably to the spreading out on the surface of the fresh water from the tributaries, and not all at once mixing with the water below. If there were no tributaries the mixing would be perfect at no great distance from Teddington, because the action of the mixing is so great, 9532–5. Diagrams 5 and 6 are to be taken together, and they show the amount of sewage in the river at the different places. By means of the chlorine analyses he is able to divide the water above Crossness into pure river water and water which has passed Crossness once, because it has a greater density than pure water, 9536–41. The vertical ordinate on the diagram at Teddington represents the section of the river, which is all fresh water there. The left-hand hatched line represents the whole river section. The whole of the cross-hatched part, including that marked sewage, is the quantity of Crossness water found by calculation to be in each section, and the dotted line with the hatched part to the right represents the area occupied by water which has been once at Crossness. The outer division represents the water which has never been to Crossness, 9542–52. Below Crossness the water in any section consists of water which has come up from the sea and water which has gone down from Crossness. Knowing the amount of chlorine in the water at Crossness and in sea water, he is able to tell from any sample the amount due to Crossness water, and how much has come from the sea, 9542–60. These two diagrams relate to Tables Nos. 6 to 11 inclusive, and depend upon no theory. They are a simple expression in volumes of Professor Way's analyses, and they represent the condition of the river at high and low water as indicated by the chlorine, 9563–7, 9732–8. Crossness water (by which he means the water which was in the river at the moment when the analyses were made) consists of river water, sea water, and sewage mixed. To find out the quantity of sewage there is in the mixture, three quantities, based on three equations, must be determined. First, the total quantity of salt in the mixture must be equal to the observed quantity

PROFESSOR W. C. UNWIN—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

of salt in the section. Secondly, the sum of the areas of the mixture must be equal to the known area of the section; and thirdly, the ratio of the river water and sewage water must be equal to the known ratio of the quantity of sewage and the quantity of upland water supplied in a tide respectively. The point to determine is the quantity or proportion of sewage in a cubic foot of water, and this he calls the sewage density, to which he has given values in his tables, 9568–79. Whenever the Crossness water goes up stream or down stream it carries with it the same proportion of sewage or materials which have been sewage. The tables and diagram show the distribution of sewage obtained by dividing the Crossness water into sewage, and water which is not sewage. In doing this, he has assumed that the sewage at the Crossness section bears the same ratio to the river water that the sewage supplied in a day bears to the upland water supplied in a day, and in order that that assumption may be right, he further assumes that the sewage is uniformly delivered into the river during the period of an ebb. As the tidal range contains the sewage of 12 to 15 days, the slightly non-uniform distribution of any one day's sewage very little affects the question. 9580–90, 9677–99. The entry of a pure stream above Crossness into the river is estimated as Teddington water in his tables, therefore it does not involve any error in his calculations; but a polluted stream entering above Crossness contains less saltness than the saltness of Crossness water, and is chiefly estimated as Teddington water; and therefore to the extent to which polluted water enters above Crossness the diagram shows less sewage than there really is in the upper part of the river, 9591–2. In addition to the state of the river as it actually was on the three days, he has calculated on the diagram an imaginary tide at low water, such as might occur in a period of excessive drought. He has taken the volume of upland water as being 30,000,000 cubic feet in a tide and 10,000,000 cubic feet of sewage. This would give at Crossness one cubic foot of sewage in five cubic feet of water. The quantity of sewage in other sections of the river he gives in Table 12. He has entered on the diagram an "Ideal low-water spring tide," which in a period of drought would give about 59 days' sewage in the river against 39 days on the 14th September, 28 to 31 days on the 22nd September, and about 12 days' sewage on November 30th. He has assumed that the saltness of the river from Crossness towards the sea would be the same exactly as on the 14th September, 9593–9607. Table 15 and Diagram 7 show the percentage of sewage, and the interesting part of that diagram is the way in which the per-centage of sewage is extraordinarily diminished upon the 30th November by the upland flood water. In connexion with that, the very great rise of the ideal spring tide line in drought at low water will be noticed, which is due to known diminution of the water at Teddington, 9608–10, 9776–8. The effect upon the sewage density, if the sewage was discharged at Gravesend instead of Crossness, would be to reduce the amount of sewage throughout the river to rather less than one half, but the bearing of that statement upon the inquiry is, that there is no point upon the river at which the sewage can be introduced which will keep the sewage entirely out of the upper part of the river, 9611–12. He wrote a book last year on "the "movement of water in a tidal river," and the calculations were based upon the Thames. In it he says, and he believes the statement to be correct, that the tidal action alone, independently of any mixing, effects no change in the material water of the river. It merely produces a comparatively short reciprocating oscillation of from 6 to 10 miles on a spring tide, and rather less upon a neap tide, 9613–21. Many people believe there is a more or less complete emptying and filling of the river at each tide, but this is not true, 9622–4, 9730–1. Table 1 was only a table of areas, and he did not think it was worth printing, 9634. He does not consider his method of calculating the contents of each division erroneous (viz., multiplying the mean of two sections by the distance between them). It is to his mind the most accurate method which can be adopted, considering the number of sections and the data at his disposal. The conclusions at which he has arrived are, under the circumstances, as accurate as any conclusions could possibly be from such data, 9635–43, 9757–61. For engineering purposes prismoidal rules would be more accurate, but he does not think they would be so

PROFESSOR W. C. UNWIN—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

accurate if applied to that part of the river which he has had to deal with, on account of the irregularity of its longitudinal sections. In depth between any two sections the Thames does not vary much, but its width increases sensibly, 9635–60. The whole of the canals in India have been taken out upon the plan he has followed, 9661, 9760. He is not aware that his method has produced a difference amounting to 25 per cent. between his results and those of Mr. Mansergh. Taking the section between Gravesend and Southend (which is the section in dispute), it is three-fourths of the whole volume, and there are only two cross-sections for this part of the river; the difference must be due to defective data therefore, and not to any defective calculation on his part, 9662–76, 9762–5. With regard to the belief of some people that the river empties and fills with the tide, the actual fact is that the volume of tidal water which enters at any one tide is about equal to the low-water volume. In simple words, the section of the river from Southend upwards is half filled and half emptied every tide, 9730–1. The volume brought in by the high tide from the sea contains the old sewage that has been carried down, and he has looked into the question of whether any Medway water enters the Thames at the same time. The drainage area of the Medway being one-tenth of the Thames, not more than one-tenth of the water in the estuary can have come out of the Medway, and he assumes that that tenth part, whether it is as impure as the Thames water, does not very much affect the question. The water that goes out of the Thames must, therefore, be fresh water which carries with it the same proportion of sewage. He concedes this fact, that up to 10 miles above Southend the water has come in from—he does not know where, but the water beyond that never goes out even of his part of the river at all. The salt which is found in the higher reaches of the river as far as Chiswick is, no doubt, due to the sea-water having worked its way up, 9731–44, 9771–5. He accepts Professor Way's statement that at Margate there was 12 per cent. of fresh water, and that it therefore contained a certain per-centage of sewage, because an enormous volume of fresh water goes out of the Thames daily, which does not become dissipated all at once, and a current of fresh water may have gone past Margate, 9745. Table 1 he hands in, as it is desired by Counsel, but Table 13 has never been printed. Table 14 embodies Table 13, and is in a better form, 9746–50. Before he began to consider the question of the disposal of sewage in the Thames he had made a large number of velocity and stream observations on the Thames at Putney and in the upper part of the river, 9751–6.

## MR. CHARLES MEYMOTT TIDY, M.A., M.B.

Lecturer of Chemistry and Forensic Medicine at the London Hospital, &c.

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—He has had considerable experience for some years upon matters connected with water and water pollution in the Thames, 9808. The Thames water is composed of river water pure and simple, sea water, and sewage, and it will be convenient to deal with these three classes separately at first, and take the mixture afterwards. By pure water he refers to that which comes over Teddington Weir, 9809–10. He has for many years past taken samples of the Thames water at West Moulsey, and for all practical purposes that water is the same as that which flows over Teddington Weir, 9811–13. He hands in a table showing the dissolved and suspended matters in samples of water taken from the Thames at Hampton, one foot below the surface on, or about the 15th of each month for the years 1874 to 1879. A few lapses occur because the samples were not taken in the middle of the month, and he has thought it better to keep his table uniform, 9813. The solid matter appears either in solution or in suspension. The matter in solution and suspension may be divided into organic matter and mineral matter; and the organic matter consists of vegetable or animal substances, 9814–18. The table refers only to dissolved and suspended matters, not to any mineral matter. When the water is "very slightly turbid" minute particles can be seen, but cannot be estimated. "Slightly turbid" means something more than very slightly turbid, and the water is said to be "turbid" when it contains less than or somewhere

MR. C. MEYMOTT TIDY—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

about one-tenth of a grain of suspended matter per gallon; that is to say, between one-tenth and one-quarter, 9819–20. The average of the river with regard to suspended matter varies a good deal according to the quantity of flood water, but from the table it appears that the quantity of suspended matter in the river at Moulsey is very small, and the turbidity of the water may be due to an almost inappreciably small quantity of suspended matter, as a very small amount will make water appear perfectly turbid, 9821–2. The total solid matter in solution in Thames water varies from 17 to 22 grains per gallon. He never knew it to be below 16 or above 23 grains. It varies at different times of the year, showing a perfectly well-defined wave in the course of the year, and the maximum or crest of the wave is reached about February; the wave can only be properly ascertained by taking a very large number of experiments, and his table refers to filtered water entirely. The lowest point occurs about August, 9821–30, 9833. The same law would apply in a great measure to unfiltered water, 9831. From February to August the quantity of chlorine in the upper part of the river is about $1\frac{3}{10}$ grains in a gallon, and from September to January about nine-tenths of a grain. The normal quantity may therefore be considered as one grain per gallon. It is very difficult to say to what cause the presence of chlorine is due in that part of the river, but all water contains a certain small quantity of chlorine in the form of common salt, 9832–7. The general constituents of the mineral matters are unimportant in considering the purity of the Thames water, but the chlorine and the total solid matter are important, and the magnesium is of a certain importance, 9838–9, 10,161–86. The only method of estimating the organic matter in the river is by the combustion process, that is to say, by the estimation of the organic carbon and of the organic nitrogen in the water. This was suggested by Dr. Frankland. The albumenoid process would not give any reliable results, 9841–2, 10,161–86. The organic matter varied from ·072 to ·256 grains per gallon in 1881, and the ratio of the nitrogen to the carbon (which together make up the total organic matter present) indicates somewhat the kind of organic matter present, that is to say, whether it is of animal or vegetable origin. The ratio of nitrogen to carbon is about one to eight, 9843, 10161–86. The proportion of ammonia in the river above Teddington is so small that for all practical purposes it may be taken as nil, 9844. It depends on the nature of the organic matter whether it is injurious to water. That in the Shannon, which is derived from the peat bogs, is not in the least degree injurious, and the water is some of the purest in the world, 9846. He tested the water for nitrates as well as for ammonia, and found (speaking from memory) two-tenths to three-tenths of a grain of nitrogen as nitrates per gallon, 9847–8, 10,161–86. For the last two years he made seven determinations daily of the free oxygen in solution in the water supplied to London. It varies from $1\frac{7}{10}$ to $2\frac{2}{10}$ cubic inches per gallon, according to the temperature, but generally the Thames water contains two cubic inches of free oxyge per gallon (or 277 cubic inches), 9848–51, 10,161–216, 10,616–21. When the ratio of nitrogen to carbon increases it indicates animal rather than vegetable contamination, which is infinitely more dangerous than vegetable contamination. Therefore, the larger the ratio of nitrogen to carbon, the more polluted the water becomes, 9852–3, 10,267–76. The composition of the Thames water above Teddington is singularly constant, and indicates water of a very considerable degree of purity. The suspended matter in the higher reaches is nearly always of the nature of clay and sand mixed with occasional particles of vegetable matter or fibre. The specific gravity of this suspended matter is about $2\frac{1}{2}$; it is very finely divided, and is very long retained in suspension, 9854–6. The quantity of free oxygen in the water is determined by a modification of Schutzenberger's process. Every tenth determination was actually done in addition in order to see how far it corresponded, 9857, 10,187–203. The organic carbon varies from ·103 to ·364 in 100,000 parts, and the nitrogen is an eighth of that, 9858–60. He has a diagram which gives the average results of about 1,200 analyses of the filtered Thames water, and shows the complete wave formed by the suspended matter in a year, 9861. He has examined the composition of the sea-water on a great many occasions, and the results confirm almost

MR. C. MEYMOTT TIDY—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

entirely those which have been arrived at by the Rivers Pollution Commission and mentioned in their sixth Report. He hands in a collection of Tables and Diagrams (*see* Appendix A. G.), 9862–3. He has inserted amongst the samples one of the Dead Sea water, which is curious from the fact that the nitrogen actually exceeds the carbon, viz., ·3 per 100,000 of carbon to ·4 of nitrogen, 9863–4. In all sea water the nitrogen is at a very much higher ratio than in fresh water. It may be taken at about one to one and a half. It is not by any excess of the nitrogen, but by decrease of the carbon, which is more easily oxidized than the nitrogen. At Southend, in October and June, the nitrogen was in excess of the carbon, 9865–9, 10,001–3. The amount of ammonia in sea water is almost nil, which is of importance in tracing sewage, and the amount of nitrogen as nitrates is also small. At Brighton the free oxygen in solution varied from 1·7 cubic inches to 2·1 cubic inches per gallon, which is much the same as in river water, 9869–75, 10,214–26, 10,616–29. With regard to chlorine, the amount varies considerably, as shown in the tables. The samples taken at Southend are perhaps the most interesting in connexion with this case, as they vary from 1,246 grains at low-water on the 16th October to 1,558 grains at high-water on the 10th June. From this it is found, in nearly all the samples, that the total quantity of solid matter and of chlorine is greater at high-water than at low-water. There is one exception to that, and he cannot explain it, in the case of Brighton in September 1882, 9876–78, 10,124–60. He made analyses in 1875 of samples of sewage taken at mid-day from ten of the large city sewers, and found an average of 94 grains per gallon of solid matter in each; 56 grains were in solution, and 38·15 grains were in suspension. Of that 94 grains, 31 grains were organic, 15 grains of which were in solution, and 16 grains in suspension. Night sewage varied from day sewage, not containing so much matter in suspension. Storm sewage varied from both. Exclusive of storm sewage, the general proportion of suspended matter in ordinary sewage contains about 25 grains per gallon. The average would be taking all sewage from 45 to 50 grains per gallon of suspended matter, 9879–83, 10,306–42. Storm sewage has been known to contain over 164 grains per gallon. It is due to the detritus of roads and accumulation in the pipes, 9884–6, 10,346–65, 10,667. The strength of the sewage in solution varies very much according to the time of day. It is at times strong, and at others weak; but as an index of the organic matter the organic carbon shows a maximum of about 5·4 and a minimum of about 3 in 100,000 parts. The average would be about 4·3 per 100,000. Organic nitrogen ranges from 3·8 to 1·3, and the average may be taken as about 2·5 per 100,000 parts. The ratio of nitrogen to carbon is as 1 : 1·77, which is very different from the proportion in pure water, and is more like that which is found in sea water, 9886–92, 9898, 10,267–305, 10,366–85. The quantity of ammonia in sewage is large, and varies from 6½ grains to about 2½ grains. (With the exception of nitrogen and carbon, which are given in parts per 100,000, he gives all his results in grains per gallon.) A fair average, taken from a number of samples not the mean of the two numbers, is about 3 grains of ammonia per gallon, 9893–5, 9933. The average amount of chlorine in London sewage is about 10 or 11 grains per gallon. The quantity varies considerably, and often reaches 10 parts in 100,000, but that really makes very little difference, 9896, 9900. To detect sewage in a mixture of pure water, sewage, and sea water, ammonia is decidedly one of the chief things. Free oxygen dissolved is also important, and he will discuss that presently, 9897, 9899. Of the London sewage, 80 per cent., or 37 gallons of water per head, represents the water supply. It is 10 parts per 100,000. This is from his own observation, confirmed by others, 9901–2. In calculating the amount of polluting matter which goes into the Thames, he has adopted the figures of Röder and Eickhorn, two great German authorities. From a large number of experiments, each person voids about 1,750 grains of fæces daily, excluding urine, which is equal to four ounces; 75 per cent. of that is moisture, and 25 per cent. or one ounce is dry matter. This is equivalent to 444 tons discharged daily into the Thames from a population of 4,000,000, of which 111·6 tons are dry matter, 11 tons of that being soluble, and 11½ tons insoluble, 9901–6. Of urine the amount

MR. C. MEYMOTT TIDY—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

is 376,605,555 gallons, or 1,681,274·8 tons are discharged into the river annually. The dry solid matter in urine amounts to 2½ ounces per head, which, added to the dry part of the fæces, gives 3½ ounces of dry matter per head per diem, which corresponds with Mr. Latham's estimate, 9907–11, 10,409–28, 10,439–54. This estimate does not include the other matters which go to make up sewage, and which contain more polluting matter than actual sewage, 9912–13. The insoluble matter which goes into the river floats about, and, no doubt, combines with the alluminous compounds from the alluvial mud which are raised by the tides and passing steamers, and so it is deposited on the bottom, causing, in his opinion, a very serious nuisance in the river, because it undergoes putrefaction and developes putrefactive gases. It is rendered lighter by putrefaction and rises again, and the offensive gases are given off to the air. It then sinks and the process is resumed. In the case of oxidation there is not much nuisance, as the products are not offensive. The soluble matter undergoes oxidation as far as it can, and as the quantity of oxygen in the water diminishes, so a less purifying power is found in the water, 9914–23, 10,481–9. On the 15th November 1879, when on the river with Dr. Frankland, the weather being frosty, he saw a rapid stream of sewage, calculated at from 20 to 30 million gallons (a day), flowing over the apron of the northern outfall at dead low-water. Owing to the amount of steam given off, the entire volume looked boiling hot, and from the bed of the river he noticed a bubbling up of gases indicative of the most active putrefaction. The smell was exceedingly foul. He noticed a similar thing going on in Barking Reach on the same day, and such a condition could only point to contamination with comparatively recent sewage undergoing decomposition. He is convinced from that and other inspections that, under certain conditions of water and of tide, a very great nuisance must undoubtedly exist, 9924–6, 9928–9. He is unable to give any reliable information as to the time sewage takes to putrefy, owing to the variable distance it has to travel as well as to the fact that the different kinds of putrescent matter present are influenced by different degrees of temperature, 9927, 9930, 10,109, 10,110. In order to arrive at some notion of the general composition of the river at different points, he divided the river into lengths, and personally (with two exceptions, Nos. 35*a* and 44) took samples from each division at one foot below the surface in mid-stream, to avoid any impurities floating on the surface. The results he has arranged in different tables and diagrams, and he hands them in (*see* Appendix A. G.), 9931–3. The river he has divided into the following sections, Teddington to Battersea, Vauxhall Bridge to Deptford, Greenwich to the Royal Albert Dock, Beckton to Crossness, and Erith to Purfleet, 9934 On the diagram all the results are shown in grains per gallon, except the organic carbon and nitrogen, which are shown in parts per 100,000, and free oxygen, which is given in cubic inches per gallon. On Diagram A. the numbers 1 to 58 correspond with the numbers of the samples taken, as shown on Table I. The numbers on the left hand represent the quantities per 100,000 parts of organic carbon and nitrogen, and the figures at the lower part of the diagram represent the cubic inches of free oxygen per gallon, as shown by the lines on the table, 9935–40, 10,366–70. In the first "reach" or "section," which extends to No. 25, the quantity of organic carbon is ·216, and the quantity of organic nitrogen is ·028 per 100,000 parts; the ratio of the nitrogen to the carbon is as 1 : 7·7, and the quantity of free oxygen 1·48 cubic inches per gallon. The free oxygen below Teddington is reduced very nearly by 25 per cent., but the ratio of nitrogen to carbon is practically the same. The water remains nearly as pure, but it is at the expense of the oxygen, 9941–8, 10,370–2. The tributaries are marked by spots in circles, and are placed on the line representing their junction with the Thames, but in a position on the scale to mark their degree of impurity instead of raising the Thames to that point on the scale, 9938, 9949, 9975–8. The ammonia is very little altered, and the matters in suspension in that reach average eight-tenths of a grain per gallon, 9950–1. The second reach includes the numbers 26 to 35, and in it there is a manifest increase of organic matter, the organic carbon has gone up from ·216 to ·323, and the organic nitrogen from ·028 to ·054 (or double the quantity) in

Mr. C. MEYMOTT TIDY—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

100,000 parts. The ratio of nitrogen to the carbon is as 1 : 6, and the free oxygen is reduced to 1·3 cubic inches per gallon. In this reach the call made on the oxygen is almost the maximum it can bear, and as a result the maintenance of purity is manifestly a difficulty, and at times no doubt it is impossible. He attaches great importance to maintaining full aëration for water, because he is quite convinced that, in effecting the purification of the river, the half inch of free oxygen in solution between 1·5 and 2 cubic inches is infinitely more powerful than that the half inch between 1 and 1·5; that is to say, that if a river has 2 cubic inches of free oxygen per gallon, and a purifying power of four, a river which contains 1½ inches per gallon has nothing approaching a purifying power of three, 9950–4, 9962–6, 10,001–3, 10,387–99, 10,611–15. The third reach extends from Nos. 36 to 42, and here the water becomes manifestly less pure; the organic carbon is doubled and the organic nitrogen quadrupled as compared with the last reach; the ratio of nitrogen to carbon is as 1 : 3, and the free oxygen is reduced to 0·7 of a cubic inch per gallon. That indicates that, owing to a continuous stream of impurity, the normal purifying action of the river is interfered with, and its power of reparation is seriously lessened, 9955–6, 10,001–3, 10,379–83. In the next reach (from Beckton to Crossness Reach), Nos. 43 to 53, there is a very large increase of organic impurity in the water. Thus the organic carbon is one-sixth greater than in the third reach, and 340 per cent. greater than in the first reach, while the organic nitrogen is 1,000 per cent. in advance of the samples in the first reach. The ratio of nitrogen to carbon is as 1 : 2·5, but the quantity of free oxygen is a little less, but not much, than in the previous reach. The importance of this fact is that by a constant pouring in of sewage the self-purifying power of the water is practically reduced to a minimum. Its power is exhausted, because the sewage is poured into a mixture of salt water (which is antiseptic), and water in which there is practically no oxygen on account of the quantity of sewage already in it. The sewage, therefore, to a great extent remains in its original condition, 9957–61, 10,001–3, 10,376–80, 10,384–6, 10,677–8. The Ravensbourne, which enters the Thames at the beginning of this section, is purer than the main river, 9967–8. In the last section, from Erith to Purfleet, the organic carbon is ·718, the organic nitrogen is ·176, the ratio of nitrogen to carbon 4·0, and the quantity of free oxygen ·508 cubic inches per gallon. He is quite unable to explain the alteration in the ratio of the nitrogen to carbon. He has determined the quantity of ammonia which is given in the large table, but the estimation of ammonia is not a very accurate thing, and for this reason it would have been better if the analyses for ammonia and free oxygen could have been made at once on the river, and so have avoided shaking and the access of air to the samples, 9969–74, 10,373–5, 10,404–8. He wishes to correct an error in the table in which the free oxygen of the Wandle is put down as at ·01 instead of ·1, 9979–81. He hands in the analyses of water taken at Allhallows Pier (*see* Table 13, Appendix A. G.). Evidence he believes has already been given respecting them, and he has no remarks to make on them, beyond that they are confirmatory of the other observations, 9982–6. The samples taken at the northern outfall at Barking were not taken by him, and Table No. 5 shows very little, as the samples, on analysis, show that it was not pure sewage, but a mixture of sea water, sewage, and river water. Some had a strong sewage odour when taken, others developed an offensive odour after being kept. The quantity of free oxygen in the samples is worth noticing, as it would not exist if it was pure sewage, 9987–9. As the outfall at Crossness is below the level of the river, the samples taken there must contain a mixture of sewage and sea water, and it was hardly worth while taking them at all. He hands in the analyses (*see* Table 6, Appendix A. G.), 9989–92. He hands in the analyses of the samples taken at Beckton (*see* Table 7). He took samples of the actual sewage itself on the dates mentioned in the table, to see how far the Thames was polluted by the discharge. Sea water to a considerable extent was mixed with the sewage, and the amount of organic carbon and organic nitrogen is comparatively small. The quantity of ammonia present was very large, but this is due to the slight leakage from the gas works, which cannot be prevented. The ammoniacal liquor

Mr. C. MEYMOTT TIDY—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

the Gas Company converts into salts of ammonia, so it is against their interests to allow it to run to waste. He found some chlorine also in the samples, which indicates some backward flow of sea water, 9992–9. The suspended matter at Crossness is considerable, and the samples, which are purer sewage than the others, contain an average of 30 grains of suspended matter per gallon, 10,000.

He has examined some thousands of the deposits in the various waters of the Thames microscopically, and in doing so examined the samples as they were, and also employed hæmatoxylin as a staining fluid, 10,005–6, 10669–75. The system he adopted was, first, to collect the whole of the deposit from a water sample, and mix it with distilled water (he did not filter it), so that the mineral deposit should sink, leaving on the surface the lighter and flocculent organic matter. In all the cases, where possible, he took a duplicate sample, and added a solution of hæmatoxylin to bring out more distinctly the animal tissues. Before doing this, however, he examined the appearance of fæcal matter, and a water in which fæcal matter, mixed with other mineral matters, were added. The basis of his work was a recent publication of the researches of Professor Nothnagel, in which it is pointed out that the substances of almost, if not, constant occurrence in fæcal matter were—

1. Muscular tissue.
2. Yellow elastic tissue fibres.
3. Shreds of fibrous substances, such as fasciæ, and
4. Spiral and free vegetable cells.

Of these last he has a good deal to say, 10,005–10. The mud when taken from the bed of the river has in the majority of cases an absence of smell, but when kept in a warm laboratory the smell readily becomes very offensive. This is probably due to putrescent matters undergoing decomposition. Another characteristic of sewage deposit is a flocculent and ill-defined surface, whereas in a non-sewage deposit the surface is perfectly smooth and well defined, and the supernatant liquid is fairly clear. The dimness of the sides of the glass is also a very marked feature of the observation in the case of sewage, 10,011–16, 10,082–3, 10,669–75. He commenced his microscopical observations in 1879, and has carried them on to the present time on every description of samples, 10,017–18. As regards muscular tissue, fragments of muscle with distinct striation are constantly found in fæcal matter, but rarely in sewage mud and deposits. This is due to the fact that striated muscle rapidly undergoes decomposition, and that loss of striation is amongst the earliest signs of decomposition. Where this occurs it is practically impossible to identify muscle in the mixed solution. He hands in some chromo-lithographs to illustrate the appearance of some of these specimens under the microscope, 10,017–21, 10,055, 10,090–2. The yellow elastic tissue is exceedingly important and exceedingly characteristic of sewage, because, unlike muscular tissue, the fibres resist putrefaction to an extraordinary extent, but they also resist the action of very strong chemical solvents for a very long period. They become clearer, when found, from having passed through the alimentary canal, and from the action of the water. These fibres are very frequently met with in muds, and also in the deposits near the outfalls. He never looks for the striated muscle now, as he knows how readily it disappears, 10,022–6. Shreds of fibrous substances are very often met with, and they too resist decomposition for a very long time. Particles which probably make up the tendonous and fascial tissues are often to be found near the outfalls. He has found them in samples under the microscope, 10,027–30. The fourth division is the spiral and other vegetable cells and appendages. This is a matter of the utmost importance. The appearance of vegetable matter and particles of vegetable cuticles are of no importance in determining the fæculent nature of any deposit, but there is a very great peculiarity in the vegetable matter which has passed through the alimentary canal by setting free the solitary vegetable cells or more especially the spiral vessels. Plate 3 shows that the free spiral vessel has no investing membrane round it. It is very difficult to decompose it at all. The spiral cells cannot be mistaken, as they are as definite as possible, and are perfectly clear, there being no hazy outline about them, 10,031–8. He has found hairs of

MR. C. MEYMOTT TIDY—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

wheat and other cereals constantly in the sewage mud, which at first he took to be broken bits of diatoms, and occasionally he finds starch cells, 10,039–42. One of the most characteristic features of fæcal deposit is the yellow amorphous matter. It is entirely different in appearance to non-sewage mud when seen under the microscope, as it resembles portions of disintegrated muscle and matter from the dissecting room, which have been in the water a long time, while a non-sewage deposit has a perfectly definite appearance, and consists mainly of a number of sharp particles of angular shape which are highly refracting, and evenly cover the whole field, 10,043–51, 10,669–75. The particular feature of vegetable decomposition is a coarse sort of breaking up. It is difficult to express what takes place, it is in large pieces, and nothing like the amorphous granular material distinguished by the breaking up of animal matter. He has no doubt that the yellow amorphous matter is of animal origin, but has wondered sometimes whether the yellowish material may be due to bile in any way, 10,052–4, 10,669–75. He has found living organisms present while decomposition is going on, and has examined them, and has examined into the diatom, the shells of which are found in nearly all the cases of sewage mud. In some of the mud the diatoms will be found in active motion, but they are not so frequent in non-sewage mud. He has never been able to connect diatoms with the sewage, and it is equally difficult with respect to the animal life which is generated under those circumstances. It is very difficult to deal with the question of living organisms, and he cannot distinguish between those developed in vegetable and in animal matter. With regard to young vegetable cells, the cell loses its characteristic aspect the moment its cell wall breaks, but this would not account for the yellow amorphous matter, 10,056–60. On Plate A, fig. 2, there are some yellow masses, quite distinct from the yellow amorphous material, which are nearly always found in sewage deposit, and are undoubtedly of animal origin, because there is an entire absence of vegetable characteristic about them, secondly they present the precise aspect of disintegrated animal tissue, and, thirdly, because he has found several times pieces of muscular tissue at one end converted into a yellow mass on the other, *see* fig. 2 c. He found a specimen of this in the mud at Barking outfall, and he thinks distinctly that it is an adipoceratous condition, 10,061–5, 10,669–75. In fig. 3, Plate B, a portion of tendon or fasciæ found in a water deposit collected at All Hallows Pier is shown converted into a yellow mass, 10,066–7, 10,669–75. Where sewage is found, perfect fusiform diatoms are invariably found. He does not think so much of them now as he did at the time of the Mud Inquiry. They may have something to do with the question, 10,068–9. He now directs attention to Table A, figs. X and Z, which represent a sample of sewage mud and non-sewage mud. If any of the decomposition was due to bodies of animals, the decomposition would appear *en masse*, and hairs of animals would be found more frequently in the river; but in the numberless deposits he has examined he has only found a hair but once, and that belonged to a mouse. (He has heard that at Bedford the pumps have been choked by hairs.) Hair is very indestructible. From this the inference may be drawn that the decaying matter comes from the sewage deposit, and the constancy of the appearance along the river suggests to him a constant supply of the material, 10,070–7, 10,109. He has found cotton and woollen fibres, house flannel fibres, and many other things, too numerous to mention. He has no doubt that amongst them he has met with blood cells. The absence of hair is to him a very astonishing thing. Fragments of dead worms he has frequently seen, but is unable to say what sort they were, 10,078–81. He is able to trace the distinct characteristics of sewage mud by their changing their character. Firstly, as the sewage goes down the river, the solid constituents, by reason of their different specific gravities, undergo a process of sorting, the lighter particles being carried farther than the heavier particles. The yellow fibrous material drops out first, and is lost in the further deposits; then the spiral vessels drop out, leaving the yellow amorphous matter as the last remnant of sewage in the deposit. The appearance of these two bodies in conjunction is very important, because the spiral vessels are of vegetable

MR. C. MEYMOTT TIDY—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

origin, and it indicates almost absolutely that the material has passed through the alimentary canal; and the yellow amorphous matter is of animal origin—so you get a combination both of animal and vegetable origin indicative of sewage, 10,084–8. Although the microscopic evidence is in no sense quantitative, it is in some wise relatively so, for instance, he has found spiral vessels at Hammersmith rarely, but occasionally at Battersea. At Deptford they are fairly frequent, and as he is unable to give the numbers for these places, they must be taken generally. He has never found spirals at Teddington. He further explains his meaning by reading extracts from his notes on the examination of the suspended matter in the water, 10,097–100. 10,111, 10,602–6. It is difficult to say whether the organic matter in the mud keeps pace with the number of particles in the microscope, and whether the quantitative determinations of nitrogenous matter increase as you get nearer to the outfalls in the same way as the various particles increase, he would not like to say, off-hand, 10,101–2. He does not think the quantity of organic matter in the mud conveys much: it is rather the kind of organic matter that is important. He would prefer to regard the relation of nitrogen to carbon as the more important element in determining the character of the mud, 10,103. He has no doubt in his mind that the Thames in the higher reaches is being rendered impure by the outfalls of the Metropolitan Board of Works. The discharge of 400 tons of material every day into the river cannot do otherwise than foul it, 10,108. The smell in the water is partly due to the reduction of sulphates, as a result of which sulphides are formed, the action of carbonic acid on which sets free sulphuretted hydrogen. With regard to the absence of hairs, he now is of opinion that none of any size would pass through the pipette, 10,109. In making his experiments, he allowed the samples of mud to stand in some cases 24 hours before drawing the floating matter into the pipette, but whether the flocculent matter was one per cent., or more, or less, of the total suspended matter, or what percentage of sewage was in the mud, the microscope gives no information whatever, 10,112–18. Nor does it give any information as to the age of the sewage beyond the fact that the presence of striated matter indicates sewage of the most recent deposit; and so on, 10,119–20. He has traced the yellow amorphous matter as far as Chiswick in suspended matter, but at the Mud Inquiry he had traced it as far as Teddington in mud samples, 10,121–3, 10,607–10.

He has confidence in the accuracy of his determinations of chlorine to the extent of 2 per cent. He is quite ready to admit an error up to that amount, and is certain that on the 10th June 1882 the water at Southend contained 1,558 grains of chlorine at high water, although he cannot explain it. He made the analysis himself. On the 28th January 1882 the water in Mid-Atlantic contained only 1,261 grains, 10,124–44. 1,558 grains per gallon is equal to 2,225 parts in 100,000, and 1,961 grains of chlorine would equal 2,581 grains of salt, which would represent almost the entire solid matter contained in a gallon. This does not represent common salt, but would include chloride of magnesium, 10,145–50. At high water at Southend he would not expect to find much fresh water. He has not considered the question of fresh water coming into the river from below Southend, and has worked entirely from his own experiments without any comparison of the Engineers' tables. His dates do not synchronize with their dates, and he would wish to think over the matter before answering questions on the subject of fresh water at Southend, and his analysis of the salt in the water there 10151–60. As regards the process for obtaining the amount of free oxygen, he believes that the old process is not so reliable as the present one. The analysis used to be made with a Cooper's tube, but now he measures the oxygen in one of Dr. Frankland's gas apparatus. The Schutzenberger process gives a slight error, but it is not of any moment, 10,187–203. The oxygen in solution never falls so low as 1·1 at Teddington in the summer by the new process, the average in January 1882 from a series of experiments being 2·18, in July 1·77, in August 1·78, and 1·85 in September, 10,206–16. If the quantity of free oxygen in sea water was less than that in river water, there would be a gradual diminution in the oxygen as you went down the river,

Mr. C. MEYMOTT TIDY—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

but his observations have led him to say it is not less. At Southend Pier, at high-water, his analysis shows that the amount of free oxygen is 1·39 at the bottom and 1·31 at the surface, and it is perfectly manifest that on the day the samples were taken there was less free oxygen at Southend than at Teddington; and, as he has said before, the only sea water he has tested for oxygen was at Brighton, which gave a result varying from 1·7 to 2·1 cubic inches. There are very violent fluctuations in the amount of free oxygen without any apparent cause, and these he has shown in his tables. For example, at Chiswick and Erith there are very remarkable variations, and the results he has obtained at Erith from the water have been in many cases very incomprehensible. If the inferences were drawn from a single place or determination, his reliance on the influences and deductions from the tables would be shaken, but in recording the analysis you cannot take one single thing and draw deductions from it, 10,217–40, 10,626–45. It is quite possible that when his samples of water stood for 24 hours before being analysed oxidisable sewage matter would take up a certain quantity of free oxygen, but if the bottle was quite full and the stopper put in so as to prevent any shaking, the oxidisation in the bottle would be reduced to a minimum, 10,241–44. In some experiments he made on the Shannon water, into which some sewage (organic matter) flowed, he made an analysis on the spot of one sample, and then made another analysis of a similar sample when he reached home. There was a difference in the amount of free oxygen; in the latter case it was less than in the former, but the difference made no alteration in the first place of decimals. If a bottle is not filled, and is shaken about and taken home, there is a difference. One reason why sewage in a bottle oxidises more slowly than in the river so long as there is oxygen to take up is, that it is not possible in a laboratory by shaking up a bottle to imitate what goes on in nature; there is no vegetation in the bottle, and you lose the chance of setting free oxygen in a somewhat hyper-active condition, 10,245–55, 10,622–25, 10,666. There is no doubt that fresh sewage matter does oxidise, and in so doing necessarily takes up oxygen from the water of the river, therefore, when a diminution in the quantity of oxygen is found below where the sewage is placed, it indicates the burning of the sewage. And, again, if there is a small quantity at one place, and more lower down, it either means that the water coming in has contained a large quantity of oxygen, or that the river is recovering itself and becoming more oxygenated, 10,256–61. While quite admitting that the diminution of oxygen in the Thames may materially influence fish-life, although he does not know the quantity of oxygen necessary to maintain fish in water, yet he considers the setting free of the sulphuretted hydrogen from the reduced sulphates of the sea water, which sets free a noxious gas, is itself infinitely more deleterious to animal life than the mere reduction of free oxygen, 10,262–66, 10,676. In calculating the average results from the samples taken from the City sewers (*see* Q. 9879 *et seq.*), he took the simple arithmetical mean of the figures without considering the length or size of the sewers, and at that time he had not seen Dr. Letheby's tables, he only referred to the laboratory book. He is afraid his results are not absolutely reliable; he does not put them forward as such, for no results can be absolutely reliable, he is sorry to say, 10,306–41. Omitting storm sewage, the sewage delivered at Barking and Crossness contains an average of about 25 grains to the gallon. This may be called normal sewage. At the time of the mud inquiry he stated that it contained 22 to 23 grains, but he should have said about 24 grains, or 23 to 25 grains, 10,342–46 The proper way to take the samples would have been to have a series of people along the river taking them simultaneously, but that was impracticable. He therefore took them himself on different days, as nearly as possible at the same time, viz., at about half-way between high and low water, with a few exceptions, 10,370–83. The sample taken at Beckton, being actual sewage, is not a fair sample, and he would not have inserted it in the table, had it occurred to him, 10,384–7. That which renders the water emphatically the most impure is that which is present in the form of soluble matter. You must not judge of the purity or impurity of the water by the amount of suspended matter, 10,400–1. He cannot account for the comparative absence of free oxygen

Mr. C. MEYMOTT TIDY—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

in the section from Putney to Vauxhall; it is very remarkable. The variations may be caused by the constant contest going on between the organic matter and the oxygen, 10,402–3. His figures relating to the dry fæces voided by the population he took from the works on the subject by Röder and Eickhorn, as well as from Messrs. Woolff and Lehmann, the latter being the original authority. On considering the matter, he feels bound to admit an error in the quantities which reduces the total of moist fæces from 444 tons daily to 385 tons; the dry fæces from 111 tons to 97 tons; and the solid matter in solution will be 197 tons instead of 282 tons, 10,410–38. He has not considered the extent or the dilution the sewage undergoes, because it is not (in his opinion) an important question. It is simply the addition of sewage to sewage. If it was the addition of sewage to fresh water, then the question of dilution would be important. He will assume, but will not admit it, that the sewage is discharged into a volume of liquid 240 times its own volume, and it follows, therefore, that the suspended matter comes to one-tenth of a grain per gallon. As a chemist, he has made no calculations whatever of the amount or percentage of the sewage in the river, considering it to be entirely an engineering question, 10,455–80. The pamphlet which he published, "On River water," and his remarks on the pollution of rivers by sewage, are not applicable in any way to the Thames at Barking or Crossness, because he referred to pure water and to non-tidal rivers. The Thames at Barking contains a large quantity of salt, which possesses preservative or antiseptic qualities; the oscillation of the tides carry the sewage backwards and forwards, so the sewage daily is discharged into water which is itself a kind of dilute sewage; and, further, there is a comparatively small quantity of free oxygen in the water where the sewage is discharged into the Thames; whereas in a stream which is not tidal, vegetation is found which sets free a quantity of oxygen. It is well known that a small quantity of oxygen has not the same activity that a large quantity has, and when in a nascent condition (*i.e.*, when set free by plants) it has an activity which it does not possess afterwards, 10,490–529, 10,651–65. Oscillation is adverse to the process of oxidation to this extent that there is not the same amount of purity kept up, 10,530. The Irwell, one of the rivers he referred to in his pamphlet, is more polluted where the sewage comes in than the Thames, but its colour is due to the dye-works. By "pure" water he refers to water unpolluted with sewage, and the Irwell is not so polluted at the point where the sewage enters. Vegetation exists in the Irwell below Manchester, and so the process of purification goes on, 10,531–42. Oxidation is more powerful in summer than in winter, owing to increased vegetation and light, 10,543–51. The oxygen in the river below Purfleet increases, having completed its work of burning up the sewage, if any arrives, at Southend to a certain extent; and it is due also to the oxygen in the sea water which comes up the estuary of the Thames, 10,552–72. In the former inquiry he stated, in answer to questions put to him, that "a large portion" of the sewage was oxydised or burnt up before it reached the outfalls. He should have said that "a portion" had undergone a primary putrescence, and he wishes it to be understood that, although he adopted the phrase as put to him, he now modifies the statement, because oxidation is totally distinct from putrefaction, 10,573–82, 10,592. In his opinion, the nitrogenous matter in fresh sewage is not converted mainly into gaseous matter when it reaches the outfalls, nor is there any conversion into gaseous matter in the sewers that is worth mentioning, but in the sewage there are matters of varying putrescence; for instance, the primary putrescence going on will convert the urea into carbonate of ammonia, which does not evaporate. Another thing he has noticed is that the smell from the sewage was strong in some parts of the sewers, and that it would cease for a period and be found again in another portion, 10,583–91. Not having studied the matter, he is unable to say whether the condition of the river or the emanations from it are injurious to health, but throwing 400 tons of sewage into the river undefæcated, when the whole of the solid impurity could be so easily removed, and the effluent made just as pure as the normal condition of the river, must produce a mass of emanations which he would think, from *a priori* reasoning, must be injurious to health, 10,593–601. In

## Mr. C. MEYMOTT TIDY—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

a sample of water the quantity of ammonia is less by the time you get home than when first put in the bottle, it either evaporates or becomes oxidised, therefore any details regarding it fall short necessarily of the actual facts, 10,646–50. The discharge of sewage into the Thames between Lechlade and Teddington does not cause the same nuisance as if it was poured in at one spot in a vast mass, because the sewage is now spread over a distance of 150 miles, and comes in at various places, leaving considerable distances in which the water can become pure once more, 10,654–57. He has not yet completed the promised analysis of the wells at Grays, but the quantity of salt in the Grays water is 13 grains, 10,668. He wishes to add that in making his experiments the troughs were all very carefully washed before making the analysis. There was no leakage that he was aware of, and he examined the glass to see that there was no foreign matter attaching to it. With regard to his remark that a great many of his results went against the theory of oxidation, he explains that his work was done out of doors, and in consequence of the difficulty of keeping the "blacks" out, he got no reliable results for some time, 11,277–9, 11,556–7. He hands in a photograph of the apparatus used by himself in his oxidation of sewage experiments, and explains it in detail. The amount of care he took, and the amount of labour expended in making these experiments, can hardly be imagined, and they have never been answered to his mind, 11,556–7. He points out that his statement in his pamphlet on the condition of the Irwell nine miles below Manchester is correct, and not incorrect, as stated by Dr. Frankland. "*The Stream*," he says, at Warrington has lost its offensive appearance, 11,556. He differs from Dr. Dupré's statement that the smell from the sewage is lost at a distance of 1,000 yards from the outfalls. It can be smelt at a very much greater distance, 16,227. He also denies having suggested that the fact of the oxygen having fallen below the standard amount is an indication that the river has lost its power of oxidation, 16,067–8.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The insoluble matter which goes into the river floats about, and combines with the albuminous compounds from the alluvial mud that would be raised by the tides and passing steamers. It would then be deposited at the bottom of the river, and it undergoes putrefaction. Gases develop and cause it to rise again, when the putrefying gases are given off to the air, which are most offensive. The insoluble matter then sinks again to the bottom, when the same process is repeated. This insoluble matter is a very serious source of nuisance to the Thames, 9914–19. He hands in an analysis of samples of mud supplied to him, which, owing to the quantity of organic matter, as well as the quantity of nitrogen and phosphoric acid which they contain, he has no doubt contain sewage, and clearly were taken from the Thames at different points. The samples were all dried at 230° Fahrenheit, at which temperature all water deposits and things of that kind are dried, 10,093, 10,094, 10,105–7. The quantity of organic matter was ascertained by burning; the ratio of nitrogen to carbon is estimated directly. As far as chemistry is concerned, he has no doubt that the mud samples contain sewage, without stating anything about the proportions, 10,095–6. He differs entirely from Dr. Dupré's statement that the mud in the neighbourhood of the outfalls is not worse than the average mud of the river. It contains very much more sewage than Dr. Dupré makes out. There is an amount of nitrogenised matter in it which has not been oxidised, and which may undergo putrefactive decomposition when exposed on the mud. Putrefaction is not oxidation. When oxidation takes place harmless inoffensive bodies are formed, but when a body putrifies it is broken up and offensive gases are given off. In the case of oxidation the hydrogen becomes water, and the carbon becomes carbonic acid. A small quantity of the organic matter in the mud very likely is oxidised, but the tendency is to break up and decompose into other products. The mud would then smell, not necessarily at once, but in a few days. It is possible for oxidation to go on while putrefaction is also going on, but not upon the same particles, 16,228.

## Professor EDWARD FRANKLAND, Ph.D., D.C.L., F.R.S.

Professor of Chemistry in the Normal School of Science and Royal School of Mines, and Past President of the Chemical Society and the Institute of Chemistry.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has known the Thames since the year 1845, and in 1868 he was appointed a Commissioner to inquire into the pollution of rivers and the best means of remedying it; the inquiry lasted for about six years, 10,681–3. In the year 1845, and since then, he has been in the habit of crossing the Thames twice daily, and has always taken notice of the condition of the river, 10,684, 10,977–11,005. The river, as it passed through London, diminished in purity until the opening of the main drainage outfalls. It improved for a time, but it has now become impure again, 10,685–6, 10,977–11,005. He has made several inspections of the river between Teddington and Erith, and at Teddington, popularly speaking, the river is there a pure unpolluted stream, 10,687–90. He remembers being on the river with Dr. Tidy one day at dead low water, when, to his surprise, he saw a very large volume of sewage being discharged into the river, which he estimated at between 20,000,000 and 30,000,000 gallons in 24 hours. There was a very offensive smell arising from it, 10,696–9. In 1882 he received 20 samples of water from Dr. Collingridge. They were labelled as having been collected on the 14th September, and were divided into two sections, one of which was collected at high and low water respectively, the other being taken near the surface and near the bottom at the different stations, which were as follows, viz.:—Teddington, Chiswick, St. Paul's Pier, Deptford, and Barking. He analysed the samples, the results of which appear on the tables and diagrams handed in by Dr. Tidy. (*See* Appendix A. G.) Dr. Tidy and Professor Way had similar samples sent to them, and although he has seen their results, he conducted his analyses independently of those two gentlemen. He also received some samples on the 22nd September 1882, taken at neap tide at the same places, with the exception of Barking, North Woolwich being substituted for it. Tables Nos. 11 and 12 refer to these two sets of samples, as analysed by himself, 10,702–14, 10,750. Table No. 13 refers to his analysis of the samples taken at St. Paul's Pier only from the 28th October to the 11th November 1882, 10,715–22. Diagram B. shows the ratio of nitrogen to carbon in the samples taken on the 14th and 22nd September, based on the combined tables and results of Dr. Tidy and himself. The results throughout are expressed in parts per 100,000. Diagram C. relates to the samples taken at St. Paul's Pier and at Erith upon the same days. He is responsible for the former analyses, and Dr. Tidy for those at Erith, 10,723–8. From these results he draws the following conclusions, that in spring tides sea water makes its way up to Chiswick, but not to Teddington, and that wherever sea water is found there is evidence of the presence of sewage in the increased proportion of ammonia and of nitrogen in the dissolved organic matter, 10,729, 11,109–28. He attaches great importance to ammonia as indicating the presence of sewage, but it is unfortunately a very evanescent substance, so it is difficult to say how much sewage there may have been in a sample on this account. The sewage results from ammonia may therefore be taken as the minimum, 10,729–32, 11,006–12, 11,109–28. There is very little ammonia in the river at Teddington, and practically none in sea water. When found in the Thames there are no sources of importance from which it could come other than sewage, 10,733–5, 11,096–108, 11,233–6. In those samples from which sea water is practically excluded the increase in the proportion of nitrogen to carbon indicates the presence of sewage matter, but if sea water mixes with the polluted river water, the evidence cannot be trusted, because sea water contains organic matter even more highly nitrogenous than that in sewage, 10,736–7, 11,006–12, 11,141–51, 11,233–6. The character of the suspended matter varies very irregularly in different parts of the river. It is sometimes chiefly animal, and sometimes chiefly vegetable, as indicated by the proportion of nitrogen to carbon in it. It is worthy of note that a large proportion of the suspended matter is vegetable, although nearly the whole of the dissolved organic matter is animal, being the constituents of urine, which makes a river more foul than the fæces, 10,738–42. On page 27 of the first report of Sir W. Denison's Rivers Pollution Commission this is clearly

stated, 10,741–5. Dissolved organic matter in ordinary river water is non-putrescible, and contains an average proportion of nitrogen to carbon of 1 to 7; dissolved organic matter of sewage contains an average proportion of 1 to 2; in sea water the ratio is 1 to 1·75; while in a mixture of sea water and river water with sewage it is impossible to tell whether the highly nitrogenised organic matter is derived from the sewage or the sea water, 10,746–8. The presence or absence of sea water is ascertained by the presence or absence of chlorine, and in many samples, that there was little or no sea water, is evidenced by the low proportion of chlorine in those samples, 10,749, 11,233–6. On the 14th September the ratio of nitrogen to carbon at St. Paul's Pier in the top sample was 1 to 3·1, and in the bottom sample it was 1 to 3·6. At Deptford the ratio was 1 to 3·2 on the top, and 1 to 4·9 in the sample taken 18 feet below the surface. The difference of 15 minutes between the taking of the low-water samples would hardly affect the ratio, though they might have been taken quicker. The high-water samples undoubtedly were taken at the same moment, 10,750–3. The proportions of chlorine were only 4·06 in 100,000 parts at St. Paul's Pier, and 48·9 in 100,000 parts at Deptford, both being low-water proportions. The small proportion of chlorine makes the ratio of nitrogen to carbon of importance. These results he obtained from Professor Way, 10,753–5. At North Woolwich, on the 22nd September, at low water the proportion of nitrogen to carbon at the top was 1 to 2·5, and at 20 feet below it was 1 to 2·3; chlorine in both samples 8·3 per cent., 10,756–8. He applied that standard to the samples taken at St. Paul's Pier between 28th October and 11th November, and these samples are very interesting as showing the very different condition of the river which prevails at different times (*see* Table 16). The analyses show that upon these occasions there was no appreciable sewage in that part of the river. It is due, he thinks, to the flow over Teddington Weir, which by the gaugings give for that time an average flow of 5,772,000,000 gallons daily, while the average flow is only 800,000,000 gallons daily, 10,759–63. The quantity of ammonia was ·046, 10,764. Ammonia is a good affirmative standard, but not trustworthy as a negative one, 10,765. Judged by that standard, he found undoubted evidence of sewage in the river at Blackfriars Bridge and at Beckton on the 11th July, and at the Monument and several other places above the northern outfall on the 20th and 21st June. He deduced this from the ammonia in the table of results (No. 11), 10,766–9, 11,013–19. Tables Nos. 11, 12, and 16 are his own, the rest are Dr. Tidy's, 10,769. On the 11th July the quantity of ammonia in the sample at Beckton was 3·28 per gallon, which is a little more than the average. The proportion in unmixed London sewage varies from 1·711 to 6·527 grains per gallon, the average being 3·013 grains. This ammonia he believes to be due to a stream of sewage which must have been flowing up the river near the bank on that day, 10,770–6, 10,787, 11,013–19. On the 14th September, at Chiswick, his analysis shows an abnormally high proportion of ammonia, indicative of a slight admixture of sewage. Sewage was unmistakeably present at St. Paul's Pier on the same day, and on the 22nd September it was present in the Thames at Deptford and North Woolwich to a very appreciable extent. After deducting the ammonia due to the Teddington water, the amount at North Woolwich was ·199 of a grain per gallon one foot below the surface, and ·109 of a grain 20 feet below the surface, 10,777–86, 11,233–42. Taking the average quantity of ammonia in the London sewage as the basis of calculation, the numbers he has just given for North Woolwich correspond to 6·61 gallons of sewage in each 100 gallons of Thames water at the surface, and 3·58 gallons of sewage in each 100 gallons of water 20 feet below the surface. He considers that these proportions of sewage are very serious indeed as being present at that part of the river, 10,788–91. At Allhallows Pier the water, on the 16th August, indicated an appreciable percentage of sewage from Dr. Tidy's analysis, 10,792–4. Between the 28th October and 11th November the amount of sewage at St. Paul's Pier was practically nil, though there was abundant evidence of its presence at Erith, 10,795–6. In his opinion the river is rapidly becoming worse, partly from the greater amount of sewage discharged into it, owing to the increase of population in London, and partly from the

PROFESSOR EDWARD FRANKLAND—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

accumulation of mud banks, which are increasing from year to year, even as far up as Westminster; they putrefy in warm weather and create a permanent nuisance, 10,835–40, 10,977–11,005. In 1859 he recommended deodorization of sewage to the Metropolitan Board of Works, but that deodorization has not been carried out, 10,841–3. Sewage matter is got rid of very slowly by oxidation in running water, 10,859–61. He has made careful and repeated experiments upon the River Irwell, just below Manchester, below all the sewer outfalls and all the factories, and just before its debouchement into the Mersey, which takes place above Warrington. The samples were taken on the same day, but time was allowed for the river to flow from one place to the other, and they were then compared with each other. Between those two points, a distance of 11 miles, the river falls over six weirs, a total height of 34½ feet. This fall covers the water with foam for hundreds of yards below each weir, so that it gets very well aërated at each of those weirs, 10,862–6. The purification from suspended matter by subsidence was very considerable, varying from 9 per cent. of the total suspended matter to 48·6 per cent. deposited upon the road; but the purification from polluting organic matter in solution was much less, and was sometimes a minus quantity, in other words, there was a deterioration due apparently to precisely the same water not being taken in the two places. There are practically no tributaries between the two points, 10,867–9, 10,931–4. The temperature was higher when the greater purification took place, 10,870, 10,874. The water was not examined for organisms, though there may have been some there. The river has no vegetation in that section, it is too polluted for that. The power of self-purification of a river depends upon what are called micro-organisms in it, but he does not know whether a certain quantity of impurity prevents the existence of these organisms. He believes that the putrefactive bacteria get on pretty well in any sort of liquid, 10,871–3. He wishes to explain a discrepancy between Dr. Tidy's statement and his own. Dr. Tidy stated that he examined the Irwell at Warrington; now the Irwell flows into the Mersey three miles above Warrington. The Mersey is a much less polluted river than the Irwell, 10,875–6. He made some experiments with London sewage, mixing one volume of filtered sewage with nine volumes of fresh water. After 96 hours the organic polluting matter of this mixture had only been reduced by 11·5 per cent., and after 192 hours the reduction was only 27 per cent. This bears out his conclusion that oxidation takes place very slowly in running water, 10,877–80, 11,228. He also mixed one gallon of urine with 3,077 gallons of deep chalk well water, and it was treated as the sewage was. Analyses were made from samples from time to time, beginning before oxidation had commenced. The results show that urine, when mixed even with enormous quantities of water, is, under atmospheric influences, very slowly oxidized. It would travel in a river, with a flow of one mile an hour, 264 miles before it would lose by oxidation 7 per cent. of its polluting constituents, 10,881. He confirmed these results by a further series of experiments by ascertaining the rate at which dissolved oxygen disappeared in a mixture of Grand Junction Company's water with 5 per cent. of fresh London sewage. He carefully determined the proportions of organic carbon, organic nitrogen, dissolved oxygen, and dissolved carbonic acid, and then put the mixture into well stoppered bottles, which excluded the air. The amount of dissolved oxygen and of carbonic acid was determined by opening one bottle every 24 hours. This was carried on for six days, 10,882–3. Assuming that the oxygen that had disappeared was used up in oxidizing the sewage (which, as a matter of fact, was not the case here), in the first period of 24 hours 6·8 per cent. of the sewage would be destroyed, 8·9 per cent. in addition during the next period would be destroyed, in the third period 14·3 per cent., in the fourth 5·4 per cent., in the fifth 5·8 per cent., and in the sixth 2·1 per cent. would have been destroyed, 10,884–6. The amount of oxygen which disappeared was about 15 per cent. in the first 24 hours. All the details are given at page 138 of the Sixth Report of Sir William Denison's Rivers Pollution Commission, 10,887–8, 10,929–30, 11,163–77. During these last experiments no sewage was destroyed, because if it had been so burnt up the proportion of carbonic acid

PROFESSOR EDWARD FRANKLAND—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

found in the bottles would have increased, whereas it remained exactly the same during the whole time. The sewage was only oxidized into more highly oxygenous compounds, 10,889–90, 11,163–77. Taking the Irwell experiments as a guide, it is impossible to say how far water so contaminated must flow before the sewage has become oxidized and converted into inorganic compounds. It is also the case when the sewage is mixed with large volumes of pure water, 10,891–92. The two red lines on Diagram A represent the mean between absolute high and low water on the 14th and 22nd September. They show the average of four analyses at each index point in the curves, and although the samples taken by him were not taken under the same conditions of time as those of Dr. Tidy, the lines confirm the accuracy of Dr. Tidy's table. The slight discrepancy between the red and black lines towards the end is probably owing to the much larger number of samples examined by Dr. Tidy, 10,893–7. He has no experiment in support of the conclusion that putrescible matter oxidizing in water will eventually give rise to bodies containing as large a percentage of nitrogen as carbon, 10,898. His opinion is that oxidation would probably take place more slowly in such a tidal river as the Thames than in a non-tidal river, but he has no definite observations upon the subject, nor has he any experience whether the effect of the presence of salt upon the process of oxidation when sewage is present increases or diminishes the rate of it, 10,899–901. On this question of oxidation he and Dr. Tidy are opposed as to the quickness or slowness of it, but they do not differ fundamentally upon the fact, 10,902–4, 11,212–28. He differs also from the conclusions Dr. Tidy drew as to the results obtained from the Shannon experiments, because the troughs were exposed to all kinds of dust and dirt; secondly, because, being V-shaped, the suspended matter underwent some sort of putrefaction, or at all events formed the nidus for bacterial life and organisms of that sort, which are no doubt very active in destroying sewage matter. His experience of sewage and sewage-contaminated water is that such matters purify much more rapidly by putrefaction than by oxidation. They are much more offensive and injurious while putrefying, because the gases are mixed with sulphuretted hydrogen usually during putrefaction, 10,905–15, 11,134–7, 11,212–32. Another thing occurs to him, that probably the diminution in the organic matter which Dr. Tidy found upon that occasion was due to the decomposition of urea in the fermenting matter which was deposited in the V-shaped gutters, 10,916–20, 11,212–32. It is very probable that in a river where sewage is mixed with large quantities of river water there is a great development of living organisms which play a very important part in dealing with sewage elements, although he is not personally familiar with the subject. He has made observations in the unpolluted portions of the Thames, where all these things would be in activity, such as plant life, &c., 10,921–2, 11,212–32. In his chemical analyses he does not distinguish between dead and living organic matter, and he has not made microscopical examinations of the water in that part of the river which is now being considered, to determine what the facts are, 10,923–8. The decrease of organic carbon on one occasion in the Irwell from 2·134 at Manchester (Throstle-nest weir), and 1·35 at the junction with the Mersey, with an increase of ·002 of organic nitrogen (which is practically no increase), might have been caused, if there was no other possibility, by the generation of carbonic acid gas, which would cause the organic carbon to vanish to a certain extent, but as the river at the time was in a state of putrefaction, marsh gas would generate and carry off the carbon, but not the nitrogen, 10,935–41. The river Darwen, which he examined for a distance of 13 miles, showed a decrease in the quantity of organic carbon and nitrogen to the extent of 50 per cent., but this was due to the volume of the river being doubled by the reception of unpolluted water from the streams which flowed into the Darwen between the two points. He examined the Ribble, which is an unpolluted river running side by side with the Darwen, and took the composition of the water coming in as being the same as that of the Ribble, 10,942–6. He differs from Dr. Tidy in thinking that the water in the Thames above Teddington is at all times drinkable, but between Lechlade and Hampton, where the river receives the sewage of 1,000,000 people, a number of very pure tributaries flow into the Thames, including the Wey, and a considerable quantity of chalk water from the chalk springs rising up in the bed of the Thames at Reading. Then above Hampton there is a state of things very favourable to the purification of the river, namely, an enormous filtration of the river through the gravel which comes out below the next lock, and the Lambeth Water Company is drawing nearly the whole of their supply from this gravel water, 10,947–55. During flood time the Wey is purer than the Thames, but in dry weather there is not much difference between them, 10,956–7. The filtration through gravel is a very powerful purifying process, a passage through 5 ft. of gravel is worth more than a flow of 100 miles in a river. There is a true process of oxidation going on there, and even when raw sewage is used under intermittent filtration the gravel does not get blocked up or become polluted, 10,958–9, 10,965. On the principle of water finding its own level, and assisted by the weir, which dams up the water, it stands to reason that the water in the gravel beds has flowed through from the river and rises on the other side, 10,960–4. Oxidation, he thinks, is helped by the action of bacteria in the gravel, 10,966–7, 11,232. He mentions instances of gravel which has been used for five or six years for filtration of sewage not being rendered polluted, 10,968–76. Sewage in the water, even if there was no ammonia present, would be unfit to drink, and would be prejudicial to health if used for such a purpose. As it was used by ships, it may even now be so used for drinking purposes, 11,138–40. The sewage discharged into the Lea is nothing like the amount discharged into the Thames in relation to the volume of water. At the present moment he is unable to give the number of people above the intake of the East London Water Company, whose sewage is discharged into the Lea, 11,152–6. He is aware that the sewage of some of the riverside towns between London and Richmond, as well as tributaries, drains into the Thames, but he knows of no other sources of pollution in that part of the river, such as manufactories; and there is a considerable floating population. Beyond these he knows nothing of the sources of pollution, as his analyses cannot distinguish between Richmond sewage and London sewage, 11,157–62. In the experiments he made (*see* 10,882 *et seq.*), if carbonic acid was not formed, no doubt other combinations would be formed, but nothing is known of them, whether they are more or less noxious than sewage. Sewage cannot be said to be burnt until it is resolved into the products of combustion, which are carbonic acid, water, and nitrogen. These were not formed in this experiment. Combining with oxygen is not combustion exactly, for example, it could not be said that alcohol was burnt when it was converted into vinegar, 11,163–7. In experiments such as his, he would be able to distinguish, say, one-fiftieth part of the carbonic acid that would result from the absorption of the oxygen. In those experiments the weight of dissolved oxygen was ·946 in 100,000 parts of water; 16 parts by weight of oxygen would produce 22 parts by weight of carbonic acid by combining with the carbon. In the 168 hours nearly the whole of the oxygen was absorbed, and the quantity of gas boiled off in the shape of carbonic acid was very large indeed, and there was no difficulty in estimating it. Carbonic acid can be determined with very great precision, to the extent of one-tenth of one per cent. in a gaseous mixture, 11,168–74. He has no very positive evidence of the absorption of the carbonic acid by the bacterial bodies in the water. He made experiments of that kind by putting putrescent mutton broth into an atmosphere of carbonic acid, and the liquid generated bacteria, but during a fortnight he did not notice any diminution in the volume of gas, 11,178–80. In air the percentage of carbonic acid present can very simply be determined with great accuracy, and in water it can practically be eliminated without any difficulty to about one ten-thousandth part, 11,181–4. There is no fixed quantity of carbonic acid, as the standard quantity for water. It varies very much indeed, and within high limits in different waters, 11,185–7. By comparing the composition of the water at Erith with the composition of the water at Gravesend, it shows that practically no oxidation takes place between those two places in the river, 11,233–42. He is unable to say whether the amount of organic matter in the water influences the rate of oxidation from actual experiments. He has obtained the approximate rate of oxidation in the Irwell

PROFESSOR EDWARD FRANKLAND—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

and also in the Thames, the result of which he has already stated in evidence. He has found that if a water containing a small quantity of organic matter has been subjected for a long time to oxidizing influences, it is very difficult to get rid of it. That he conceives to be the condition of organic matter in sea water, which is very difficult to touch; permanganate of potash will not touch it, 11,243–4. He believes a considerable quantity of urea reaches the Thames, but he has not looked for it, because it is difficult to detect it in polluted liquid. Once mixed with a large quantity of fresh water, its destruction proceeds very slowly, as he has explained in describing his experiments of mixing urine with the West Kent Company's water (*see* Question 10,881), 11,273–4. He gives an analysis of the proportion of nitrogen to carbon which is to be found in the component parts of sewage.

| | | | | | |
|---|---|---|---|---|---|
| Guanine contains | 1 | part of nitrogen to | | ·857 | of carbon. |
| Guanidine | „ 1 | „ | „ | ·286 | „ |
| Allantöin | „ 1 | „ | „ | ·857 | „ |
| Urea | „ 1 | „ | „ | ·428 | „ |
| Uric Acid | „ 1 | „ | „ | 1·07 | „ |

He knows of no bodies other than those produced by the decomposition of urine which would give that result, 11,274–6.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—He has compared the mud of the Thames at Teddington with that in other places, as well as taking a sample of mud from the River Mole. This contained only 2·63 per cent. of organic matter, and nearly the whole of that was of vegetable origin. The mud at Hampton, as illustrating the mud of the unpolluted Thames, contained 11·33 per cent. of organic matter, which consisted to a great extent of decaying leaves. The mud of the upper Thames was chiefly vegetable, 10,691–2. Below Teddington the river began rapidly to change for the worse, the water became muddy, and the mud became richer in organic matter, which proved, on investigation, to be more and more impregnated with animal matter as he went down the river. Opposite Deptford Creek the mud also exhibited an enormous quantity of red, or blood, worms, which used to be very abundant about Hungerford Bridge, 10,693–4, 11,265–72. They are also to be found in the mud off Blackwall Point, where also offensive gases began to rise to the surface, the discharge from which increased as he approached the two outfalls, 10,695. In 1879 the effect of sewage was traceable down to Erith, where the mud exhibited decided evidence of animal matter in it. He did not go below Erith, 10,700–1. Owing partly to the increased population of London and the consequent larger amount of sewage discharged into the river, and partly to the accumulation of mud banks, even as far up as Westminster, he is of opinion that the river is rapidly getting worse. In warm weather the mud banks putrefy and create a permanent nuisance. Even if the amount of sewage is decreased, the river will not improve as the mud banks continue to accumulate, 10,835–40. He hands in a "Report on the suspended "matter in London Sewage," written by himself. (*See* Appendix A. H.) It is a very elaborate investigation into the amount of suspended matter discharged into the Thames from the London sewers in 1878 and 1879. The rainfall upon every day is given, and the volume of sewage, the percentages of suspended matter, and the total amounts of suspended matter discharged on each day during those two years are also given. A summary at the end shows the aggregate quantity of mud discharged into the Thames during these two years, which gives—

For the year 1878, 505,257·5 tons of dry mud.
„ „ 1879, 541,965·8 „ „
„ „ 1878, 1,263,143·65 tons of wet mud.
„ „ 1879, 1,354,914·38 „ „

The wet mud is taken as containing an average of 60 per cent. of water as it was dredged up. The water was run off and the mud weighed, and then dried. It is supposed to be dry at the temperature of boiling water, 10,844–51, 11,020–37. The reason for making this enquiry was that little or no notice had hitherto been taken of the discharge of suspended matter during

PROFESSOR EDWARD FRANKLAND—*continued.*

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

storms, but only in fair weather; and he wished to ascertain what effect storms would have in increasing this quantity, 10,848, 11,020–37. During storms the proportion of mineral matter brought down is very much increased, but the mud is much less polluting than in fair weather, 10,852–8, 11,020–37. He struck out of his table (section 2) the two first observations, because they were abnormally low, below the fair weather average, in fact; had he left them in, and taken the averages, the final results as regards the quantity of mud annually discharged into the Thames would not have been very different, 11,023–32, 11,188–206, 11,245–50. After a rainfall the matter collected in the sewers during a long period of drought is carried out, but the flow will continue for a couple of days or even a week, 11,033–37, 11,063–83. He has struck out other observations which appeared to him to be of no practical use in giving reliable results, because the rainfall was so slight, but the facts given are trustworthy, 11,043–54, 11,188–206, 11,245–50. He does not believe that the system of catch-pits introduced into the sewers to prevent the road matter getting into the sewers in any quantity are efficient, as they only collect a very small portion of the mud. He has made numerous observations in London and in many towns in the provinces which confirm his opinion, 11,038–42, 11,253–6. The paucity of observations in section 4 is due to the fact, that the chemist of the Metropolitan Board of Works suspended taking his samples during a heavy rainfall, 11,055–62, 11,257–61. Table C. gives the working out and the application of the averages for 1878 and 1879, and on the day 2½ inches of rain fell the total number of gallons of sewage, plus the rain and water supply, was equal to 3,676,000,000 gallons, allowing 20 per cent. for evaporation, and as this amount is seven times the capacity of the amount that goes through the main outfalls daily, he presumes it escaped by the storm outlets, 11,084–92, 11,207–11, 11,262–4. He quotes some extracts from Sir J. (then Mr.) Bazalgette's Report to the Metropolitan Commissioners in 1853 in support of this statement, 11,262–4. The red worms he believes follow the sewage, which would account for their disappearance from Hungerford Bridge, 11,265–72.

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER.—He has used Professor Way's table to ascertain the proportion of sea water at various places on the river by means of the chlorine test, 10,797–9. The presence of sea water (in connection with the float experiments) affords evidence of sewage pollution at points far above the main outfalls, because it is obvious that the sea water cannot get past the outfalls without taking the sewage with it, 10,800. His analyses of sea water differ slightly from the results obtained by Dr. Tidy. Along the coasts it is always a little more dilute than in the middle of the Atlantic. The average quantity of chlorine he makes out is 1,975·6 parts in 100,000. He gives the quantity found in samples taken at different places on the coast, about one mile from the shore, and one foot below the surface. He thinks it very likely that the chlorine in sea water away from the shore always bears a definite relation to the total solid matter in the water, but he has not been able to verify it, 10,801–10. The average quantity of chlorine in London sewage is 10·3 parts in 100,000, in Thames water it is ·2, 10,811–12. The proportion of chlorine in all parts of the cross-section of the river is substantially the same (as shown by Professor Way's analysis), and the importance of establishing this fact enables him (and others) with much confidence to calculate the proportion of sea water in the river; at different depths and at different positions it is the same. The mixture takes place partly by eddies and partly by diffusion. It is not due to any chemical affinity, but to mere mechanical diffusion, 10,813–16. The tables he has put in show how enormous is the influence of the floods during their continuance in pushing back the sea water. At North Woolwich, for instance, during high water in September, one-third of the river was sea water, while on the 30th November at high water only one-fifteenth of the river was sea water, 10,817–19. He has determined the proportion per cent. of sea water at various points in the river from a number of samples collected on the 30th November, with the following result:—

PROFESSOR EDWARD FRANKLAND—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

| Place. | High Water. | Low Water. | Remarks. |
|---|---|---|---|
| Teddington - | Nil | Nil | There was a very heavy flood in the river at this time. |
| Chiswick - | Inappreciable | Inappreciable | |
| St. Paul's Pier - | do. | do. | |
| Deptford - - | ·95 | do. | |
| North Woolwich | 6·6 | do. | |
| Barking - - | 8· | ·17 | |
| Crossness - - | 15·3 | 8·7 | |
| Erith - - | 17· | 4·3 | |
| Southend - | 90·8 | 78·1 | |

These deductions are partly from his own analyses and partly from those of Professor Way, but the two sets of analyses agree very closely, so that there is substantially no difference between them, 10,820–30. During a heavy flood the sewage would be carried bodily down the river, but when it is discharged at or near low water, and when the flow of the river is normal, it reaches London, and under favourable circumstances it would get up as far as Chiswick, and to Chelsea under normal circumstances. It would then oscillate through London for many days, or even weeks, before it was finally carried out to sea, 10,831–34, 11,095.

## MR. JOHN THOMAS WAY, F.C.S., F.I.C.

Formerly Consulting Chemist to the Royal Agricultural Society.

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER.—Was a member of Lord Essex's Commission on Sewage, which sat for eight years, from 1857 to 1865, and also acted on the First Royal Commission on Rivers Pollution. He has had a very lengthened experience in relation to water supply and sewage, 11,280–5. He hands in a series of tables giving the results of his analyses of the samples of Thames water for the determination of chlorine. A resumé of these tables was handed in by Mr. Baldwin Latham, but it contained only a small portion of his experiments, 11,286–8. The tables comprise, first, the quantity of chlorine in 100,000 parts at high and low-water on the 14th and 22nd September 1882 at Teddington, Chiswick, St. Paul's Pier, Deptford, North Woolwich, Barking, Crossness, Erith, Gravesend, and Southend, the samples having been taken one foot from the surface and 20 feet from the surface. Secondly, the amount of chlorine at the same places between the 28th October and 11th November at 10 a.m. and 4 p.m., and at half tides. Thirdly, the amount of chlorine in sea water at Margate between the 29th October and 12th November, and also on the 30th November, and at the Nore between 24th September and 12th October 1882. Fourthly, the amount of chlorine in the water during the float experiments commencing 29th October, and continued daily till 7th November 1882 at flood and ebb tide. Fifthly, the amount of chlorine in various wells at Grays and Erith, 11,288. None of the samples were taken by him, but as it is important that the method of taking them should be given, he wishes to explain the process, 11,289–93. The object of taking the samples was to ascertain how far, and under what circumstances, the sea water, as indicated by the chlorine, went up the river. At the 10 places selected, in some cases three samples, and in others five samples, were collected at certain equal distances across the river, the object being to ascertain whether there was any difference in the flow of the tidal water. They were taken at one foot below the surface, in some cases as near the bottom as possible, and in other cases at 20 feet deep, whenever there was that depth of water in the river. Samples were also taken at high and low-tide. The letter A always begins on the south shore of the river, and a separate analysis was made for each sample, 11,294–301. The second table, called "Resumé," is the result of the averages of these others. The tables numbered 1, 2, 3, and 4, relate to analyses of water for chlorine which were or have been used in this inquiry, 11,302–6. There are two methods of analysis for chlorine, one the old or gravimetric method, in which the chlorine is collected as chloride of silver and weighed, the other by the volumetric method, in which the chlorine is determined by volume by means of a colour test. This being the simplest method, he adopted it for the purpose of his analyses. He has taken every step to satisfy himself of the accuracy of his results, but it is difficult, where there are large quantities of salt in the waters, to determine the amount of chlorine

MR. J. T. WAY—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

within one or two per cent. of the whole, 11,307–11. The determinations show the quantity of chlorine in the cross-section taken across the river, and it varies very little either across the river or by reason of depth. This is an important point. There is very little difference in the samples as taken across the river, or as taken at one foot from the surface, or taken deep. The resumé, which is deduced from the tables, and shows the mean of the experiments on Table I., may fairly be taken as proving the state of the river, 11,312–16. The observations of the 30th November were taken at one point only upon the river instead of across, but they were taken shallow and deep. It was found that there was no necessity to take them across, as the differences were so much less than the differences at the other stations, that it was not worth while to take them in so many places, 11,317–19. Urea decomposes in sewage at a very rapid rate, and can never be found in London sewage after it leaves the sewers. It becomes carbonate of ammonia. Urea is one of the most easily changed matters imaginable. As soon as any organic matter passes into it, it is changed almost immediately, 11,320–4. In his opinion three to five per cent. of sewage in the water would make it foul. This opinion is founded on definite observations, extending over a period of 40 years. He has in his laboratory a mixture containing 10 per cent. of sewage, but it is a very offensive mixture, 12,210–16. Of the sewage discharged into the Thames the liquid portion is not the most important part to consider. Sewage may be divided into three parts, the liquid portion, the heavy portion, which comes from the detritus of the streets, and the light flocculent part, which in great measure comes from the indigestible portion of the fæces, 12,217–19. Of this last part perhaps 10 per cent. is soluble, and the rest is insoluble in water. Its composition and character are, of course, well known, but, as part is swept away with the liquid, and part subsides, what becomes of it in a tidal river like the Thames cannot be known, 12220–1. He prefers to take sewage as if it were nothing but fæces and urine, though of course other things get in, but only in a small proportion. He calculates that the solid fæces with its water amounts to 1,750 grains per head of the population. Of this, one-fourth part, or one ounce, is dry matter. Roughly speaking, taking the population at 4,000,000 people, it gives 110 tons of dry fæces per day for the whole population of London, and, taking the moist and the dry together, it would amount to 400 tons daily, after deducting 40 tons for the soluble matter, 12,222–38. This result is very much the same as that arrived at by Mr. Lawes and Dr. Gilbert, who attempted to determine the quantity of sewage of a town by reference to the food, and what became of it. Another method is to take simply the solid and liquid excrement, and make a fair guess at it, and then calculate from it. This is what he has done. A third method is to determine by actual experiment, 12,239–40. He corrects an error of printing in the resumé of the chlorine experiments. At Deptford the chlorine at low-water should be 49·0 instead of 4·9, 12,252. He wishes to point out that, as the experiments upon chlorine were mainly intended to see where sea water and where river water was in the river, it was absolutely necessary that they should be correct, the question of the influence of the chlorine in sewage upon the quantity should be taken into account. This he has not taken into account for the following reason. The chlorine in the river water is 1·7 in 100,000 parts; the proportion of chlorine in the sewage is certainly not more than 20 (Dr. Frankland and Dr. Tidy put it down at 10, but he thinks it is higher than 10); and the chlorine in sea water is nearly 2,000. If an equal mixture of sewage and sea water be taken, say, 100,000 parts of sewage, containing, say, 20 parts of chlorine, and 100,000 parts of sea water, you would have in the one case 20 and in the other 2,000. The half of that, that is in 100,000 parts, there would be 10 from the sewage, and 1,990 from the sea water, so it makes no kind of difference, and the proportion of chlorine in the river water is practical evidence of sea water at that point. The difference between the 10 and the 20 as compared with the proportion in sea water would be very little more than the error of analysis, 12,253–5. He hands in a table showing some analyses of water taken on the 14th and 22nd September at the same places between Teddington and Southend, determined by Professor Wanklyn's method

Mr. J. T. WAY—*continued.*

Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

of analysis. The samples were taken at high and low water, in some cases deep and in others shallow, and they show the quantity of free ammonia and albuminoid ammonia in parts per million, 12,264–6. The albuminoid ammonia at Teddington is a fair average of what it should be before the water is filtered by the water companies. The amount increases in quantity until at North Woolwich it reaches at high-water 1·04 parts in 1,000,000. That sample stank immensely. It was probably due to the flow of the river carrying the sewage up. There is then a gradual rise to Crossness, when it begins to decrease until Southend is reached. This shows that in the central section of the river from North Woolwich to Erith there is more sewage than anywhere else. The reason it falls off there is that the quantity of sewage in proportion to sea water is so much less, 12,267–74. The reduction of sewage by oxidation at North Woolwich would be considerable; but it is well known in chemistry that non-nitrogenous matters like sugar and gum, and things of that kind, take their own weight of oxygen to consume them; and that nitrogenous matters like gelatine, albumen, creatine, and so on, require double their weight of oxygen to destroy them; if, therefore, the sewage discharged in one day (400 tons of total fæces) were destroyed by oxygen taken from the air, the air in that neighbourhood would become absolutely without oxygen. The dry matter would be, at the lowest, 100 tons; the solid matter from the liquid sewage would be 150 tons, but the residue of the urine so far as it consists of urea would not require oxygen, being converted into carbonate of ammonia, which would leave more than half. But taking the fæces alone and oxidising it would deprive the air of oxygen, 12,275–89. The reduction of oxygen in the water (referred to by Professors Heaton and Tuson and Dr. Tidy) shows that the enormous quantity of organic material in the sewage is being oxidised, and it also shows a disposition in the sewage to be oxidised, 12,290–1. He thinks the light flocculent organic matter, when it is discharged into the river, moves up and down with the tides, depositing its heavier portions. It gradually meets with the actual mud or clay at the bottom, which has a strong tendency to combine with it. (Aluminous matters have a tendency to combine with organic matters.) It then becomes heavier and sinks, especially in slacks and places where the banks are formed, and in that way a great deal of the solid matter fails to go with the liquid matter; so that, in fact, it must be accumulating at the bottom of the river. If mud that has been collected from the bottom of the river be shaken up, it settles very much faster than ordinary sewage. He has seen large deposits of this organic mud at the bottom of the river, 12,241–3. This mud is a more serious source of nuisance than the soluble part of the sewage, because the soluble part is sooner or later taken away with the water of the river, and he would not be at all surprised to find that a very large proportion of this fæcal matter is collecting at the bottom of the river in different places. Supposing it to be collected, it undergoes fermentation there, and produces gases which are some of the most noxious and objectionable; the nastiest gases of any organic matter; and when that mud is stirred it comes up, and gives off that gas. It goes down again and produces more, and it must go on doing that until it is entirely destroyed in whatever time that may take up. But the liquid matter of sewage is already in a state very far advanced in oxidation, and is on the point of passing into other materials which are not objectionable gases. It smells very nastily at first, but the oxidation undoubtedly destroys it, 12,244. The mud in the Thames becomes much more offensive when it is stirred up, or when the gases escape by themselves. They escape more readily in the four or five warm months in the year. The black mud can positively be seen coming up to the top of the river and the bubbles exploding; so also in stagnant pools the same thing can be seen, 12,245–6. In a report he wrote to the Royal Agricultural Society in 1854 he stated that the solid organic material was more productive of injury than the liquid, and he has seen no cause to change his opinion. It is perfectly well known that the deposits upon the banks of the river are the cause of the stench, which is not so bad when the river is full. Although there may be no smell at the present time from the river, when the warm weather came, and brought the mud to the surface, the nuisance would then arise; and, in his opinion, should

Mr. J. T. WAY—*continued.*

Distribution of the Sewage in the River by the various Motions of the Water—*continued.*

it go on accumulating, the condition of the river will become a very serious matter, 12,247–51. He now hands in a table of the analyses of various samples of water taken between Teddington and Southend, showing the solid residues in parts per 100,000. The samples were taken on the 14th and 22nd September at high and low-water for the chlorine experiments on the surface and in deep water respectively. They show the solid residues in the filtered water, and are matters in solution only, which become solid by evaporation, 12,256–63.

## Mr. CHARLES WILLIAM HEATON, F.I.C., F.C.S.

Lecturer on Chemistry at the Charing Cross Hospital and Examiner in Chemistry to the Royal College of Physicians.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He lives in the parish of Erith, a mile and a half from the river. He has known the river for 20 years, and during the last 6 years has been in the habit of sailing on it, 11,325–33. In hot weather he has observed disagreeable smells coming from the river, and more particularly from the mud, frequently. When near the outfalls in cold weather, and at a distance of a mile, he has detected smells on the river. In very hot weather he has smelt the water miles away from the outfall. It has come down upon the wind. The smell last summer was slight on account of the wet and cold weather, 11,334–49. In conjunction with Professor Tuson, who also lives near Erith, he has made a series of experiments upon the composition of the water from which some important points are proved. The samples they took personally, and tested them principally for the determination of albuminoid ammonia and dissolved oxygen. They also made a certain number of determinations of nitrates on special occasions, 11,350–9. The experiments were commenced in July 1882, and were made at intervals through the greater part of the remainder of the year. He hands in a table giving a list of the places (39 in number) where the samples were taken, the date, and the quantity of free ammonia, of oxygen absorbed, and of albuminoid ammonia, in 100,000 parts of water respectively. As regards ammonia, the figures are very irregular, and he does not profess to found much upon them; but they tend to show that the river is polluted, and polluted with sewage, but to the extent of that pollution he does not pretend to speak, 11,360–2. The albuminoid process gives evidence with regard to the organic matter capable of putrefaction that is present in the water. The bad smells are due to the putrefaction of nitrogenous matter, and for that purpose it was desirable to ascertain some measure of the quantity of the albuminoid matter. The organic nitrogen determination is of the greatest value, but it is to a certain extent reduced in value by the fact that sea water contains much organic nitrogen. It is well known that the albuminoid ammonia estimation only represents some fraction of the nitrogenous putrefiable organic matter, and it is agreed that in a river like the Thames albuminoid ammonia does come from nitrogenous organic matter of some kind, capable of putrefaction, 11,363–6, 11,427–9. Unfiltered water was used in the experiments so that they should represent, as far as they were able to do so, the actual condition of the river, 11,367–8, 11,480–5. In the first place they got very considerable quantities of albuminoid ammonia throughout the area examined, viz., from Woolwich to Greenhithe; at all times of the tide, and, except at high water, when there is distinctly less, the mean results of the determinations in this way do not indicate any material difference in the composition of the water. The water was examined at high water, low water, flood and ebb, and the least proportion was found at high water, but the quantities found upon either side of the top of the tide varied very much indeed, which is due to a very great extent to the use of unfiltered water, 11,369–73, 11,480–5. He used the permanganate process for the determination of the albuminoid ammonia matter, first distilling with sodium carbonate until the liquid was quite free from ammonia, 11,374. Samples 41 and 42 have been accidentally filtered, and so they are excluded from the average. Two other samples, one taken very near the outfall and the other taken in the wake of a very large steamer, have also been excluded, 11,375–8, 11,480–5. The average amount of

Mr. C. W. HEATON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

albuminoid ammonia in the sewage area during all times of the tide, and excluding Nos. 30, 41, and 42, is ·0937 parts in 100,000 parts, which is seven times the quantity obtained in Sea Reach. The method by which the albuminoid ammonia is obtained, is known as Wanklyn's process, 11,379–84. The quantity obtained is certainly less than what was in the water, because, when nitrogenous matter is distilled with alkaline permanganate, the nitrogen is partly converted into ammonia, but not all of it, and there is no formula by which they could multiply the albuminoid ammonia in order to obtain the quantity of organic matter. The way in which he obtained the quantity was by assuming Professor Wanklyn's estimate that you get two-thirds of the nitrogen as albuminoid ammonia to be correct. Then (and it is a mere supposition), it would give ·7 parts by weight of nitrogenous organic matter, estimated as equal to albumen, per 100,000 of water. He believes, in common with others, that the actual quantity of matter would be greater, as he does not think there is so large a proportion as two-thirds of nitrogen in the form of albuminoid ammonia, 11,385–90, 11,440. He has determined the quantity of nitrogen present as nitrates and nitrites in only a few cases. In Sea Reach at high water the quantity of nitrogen as nitrates and nitrites both together is ·1502 parts in 100,000, and at low water ·0760. On another day at Erith at high water it was ·1190. He made a second series of experiments, in one of which samples were taken at high water, at two hours ebb, and at five hours ebb upon the same spot. The quantities were at high water ·0975, at two hours ebb ·0580, and at five hours ebb ·0270, showing a reduction in the quantity of nitrates which is a matter of importance. At Charing Cross the quantity was ·2436 at low water. These experiments seem to him to illustrate the reduction of nitrates by organic matter which has been very ably and fully treated by Dr. Angus Smith in his last Report on the Rivers Pollution Commission; and also in a work published recently by that gentleman on the reduction of nitrates by excessive sewage matter, it is shown that the nitrogen is given off ultimately as nitrogen gas. He agrees with Dr. Smith that an excess of sewage has the effect of reducing the nitrates, 11,391–7, 11,475–9*a*. The quantity of oxidised nitrogen in Sea Reach was ·1502 parts in 100,000 at high water, 11,398. In making experiments upon dissolved oxygen, he adopted the Schützenberger process. The analyses were made in the boat, because it was found that the water absorbed oxygen so quickly if the sample was taken ashore, and there was more oxygen when tested ashore, than when tested in the boat. He describes the process of filling the bottle, and the result of the experiment in the boat gave ·10 cubic inch of oxygen per gallon, whereas in the short time which elapsed between taking a similar sample ashore and testing it, the amount was found to be ·14, though the bottle was stoppered and had a thick layer of paraffin oil at the top. After letting a similar sample stand four days, and then repeating the experiment, it contained ·38, which is nearly as high as the quantities found by Dr. Tidy. He presumes there must have been a diffusion of oxygen. This happened in every case. The experiments were made in October when the weather was cold and wet, which is more favourable to the water than in rough weather, 11,399–413, 11,423–6, 11,468–75. He hands in a table showing the amount of oxygen found in some samples of water taken at Erith on five days in October 1882. The amount is given in parts per 100,000, and also in cubic inches per gallon. The average, excluding one sample which is unusually high, is ·09 parts in 100,000, or ·18 of a cubic inch in a gallon. The quantity was so small as to be practically nil, and it shows that the impurities in the water keep the dissolved oxygen very low in spite of its rapid absorption from the air. He has no experiments taken in the summer time, but he thinks that the quantity in the summer would not be greater than the smallest quantity in October, viz., ·05 parts per 100,000 or ·10 of a cubic inch per gallon, 11,414–21, 11,443–53. He has not formed an opinion as to the amount of oxygen that is required for the respiration of fishes, but the results obtained in his experiments would, he thinks, be absolutely insufficient, that in fact it would be impossible for them to breathe with that small quantity of oxygen, 11,422, 11,454–5. In the Erith District, his figures as to free oxygen are rather lower than Dr. Tidy's, but in the other districts they agree pretty closely. The apparent

Mr. C. W. HEATON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

difference is due to the determinations being made in a boat upon the spot, and not being made on shore, 11,423–6. With regard to the quantity of albuminoid ammonia he found, in flood tide, quantities that were frequently as great as in the ebb tide when the sewage was coming down. The inference he draws from that is, that the quantity of oxygen in the water being kept constantly very low by the sewage, there is not time in the course of a single tide for the destruction of these nitrogenous matters, and also that these matters appear to undergo putrefaction first and oxidation afterwards, 11,427–9. In Dr. Angus Smith's Report, pages 45 and 46, are recorded the results of some experiments upon the artificial æration with the remark that "the albu- "minoid ammonia is not much changed in any of the "ærated specimens." This is exactly what he (Professor Heaton) found, working in a different way upon the Thames. Dr. Smith also attributes the slow disappearance of the albuminoid ammonia in his experiments to the absence of putrefaction; the numbers are 10·6, 10·4, and 10·2, 11,429. In warm weather putrefaction takes place tolerably fast, and it is accompanied by a great smell, with a disintegration and destruction of the sewage. In cold weather it goes on much more slowly, so that there is a better chance for the oxygen to destroy it. When the putrefaction of a large quantity of matter is going on, and the oxygen is being rapidly absorbed, there is a smell, but when the putrefaction is very slow there would be no smell. You may have fæcal matter in the water unoxidized, but not smelling much; it is only when putrefaction with insufficient oxidation takes place, that there is a smell, 11,430–3. He cannot with any confidence express an opinion whether the injurious effects of sewage are in proportion to the noxious smell, or whether sewage is injurious or not, 11,434–6. In cold weather the sewage remains some time in the water without changing its character, 11,437–9. On the assumption that there would be ·70 of a part of nitrogenous organic matter in 100,000 parts, (*See Q.Q.* 11,385 *et seq.*) he has calculated that,—supposing the nitrogen is given off as gas, and that the carbon is converted into carbonic acid gas,—it would require 1¼ parts by weight of oxygen in 100,000 parts to destroy the albuminoids only, taking no account of other matter in the water which also requires oxygen, 11,440. The low quantity of oxygen in the water at Erith, and the rapid absorption from the air shows that the oxygen is absorbed by the sewage bodies. So much putrescible matter is found in a flood tide that it is plain the oxygen does not destroy the whole or even any large portion of it in the Thames. Certain matters are not eaten up; the nitrogenous matters are tougher, and resist the action of the oxygen, 11,443–50. The nitrogenous matter putrefies more rapidly than the non-nitrogenous matter, but it does not oxidize to any extent until it is putrefied, The cold arrests putrefaction, and so indirectly the oxidation, and there is also a very large quantity of oxygen required. Between Woolwich and Greenhithe the water is polluted at all times of the tide with nitrogenous organic matter, and there is very little oxygen, not nearly sufficient to oxidize what is there, 11,451–3. As regards free ammonia, very little will be deduced from his experiments, except that there is general sewage pollution, because free ammonia does not bring out results which are useful, 11,483–5. Much difference does not exist between the samples, Nos. 41 and 42, taken at the Corinthian Yacht Club, at Erith, and that at Kingston; but it should be borne in mind that the Erith samples were filtered, and the Kingston sample was not filtered. This latter sample was struck out of the table because no evidence was forthcoming as to who took it, or how it was taken, 11,486–90. He had no means of determining the quantity of suspended matter at varying depths in the river, and his analyses do not discriminate between the organic matter alive or dead. He does not think that if there were a great number of microscopic animals or microscopic vegetables, algæ or confervoids, he would have had the same means of ascertaining the amount of albuminoid ammonia by analysis as he would by chemistry, because it is known, as a matter of fact, that certain sewage matters which are thrown into the river (the common sewage of the river) yield a large quantity of albuminoid ammonia. He admits the weaknesses of the method in many particulars, but it is generally agreed amongst chemists that the albuminoid ammonia in a sewage

Mr. C. W. HEATON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

polluted river does come from the sewage, 11,491–4. The sea-water contains much animal nitrogenous matter living and dead; the sample taken at night was when the water was covered with phosphorescence. Now that water, although it contains much nitrogen, does not yield albuminoid ammonia, and he thinks he can in this way, so far as chemistry is concerned, discriminate between organic, animal, and vegetable matter which is dead in the water, and animal and vegetable matter which has come out of the sewage. Unless he knew the history of the water from which a sample was taken he could only say that it was polluted by nitrogenous organic matter, but whether it was sewage, or fæcal, or from some other cause, he could not tell. Knowing sewage to be in the Thames, he has attributed it to that cause, 11,495–510. The noxious trades which are conducted on both sides of the river are very disagreeable. He has had to complain constantly of the vapours which arise from the manufactories and they exist at the present time, 11,511–14. Certain documents relating to the drainage of Erith, and to the Erith Local Board were handed in by Mr. Michael and Mr. Morice (*see* Appendix A. J.).

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He took some samples of mud at Erith, and kept them in his laboratory for some time. In a few days it smelt most offensively, and was full of large red worms, which he had not noticed before, and were certainly not in the mud when they took the sample. He presumes they were hatched, but he does not suggest that the mud contained sewage because of the presence of the worms, 11,456–67.

## PROFESSOR RICHARD V. TUSON, F.I.C.

Professor of Chemistry in the Royal Veterinary College, and Associate of the Society of Medical Officers of Health.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has been resident at Erith for 11 years, and has known the river for 22 or 23 years, having been constantly yachting all the time. He has frequently been on the river at night, and at all times of the day, 11,519–23. In conjunction with Professor Heaton, he made all the experiments which have been mentioned in Mr. Heaton's evidence, and, as far as scientific matters are concerned, he concurs in all he said in reply to the questions put in cross-examination, and has nothing to add to his evidence, 11,515–8, 11,540.

He considers himself fully qualified from personal knowledge to judge of the general condition and appearance of the river, which is steadily getting worse from year to year from Woolwich Pier to Greenhithe, setting aside exceptional seasons, 11,524–6, 11,553–4. For the last 10 years, judging from the blackness of the river, the stench arising from it, and its turbidity, it has been getting worse within those limits. In the middle of Long Reach it is turbid, black, and sewage-like, with innumerable bubbles sluggishly rising and discharging gas, and in hot weather this is accompanied by a most fearful stench. He does not notice it so much in the early part of the year, as he is not often on the river at that time, 11,527–33. A blackish kind of mud, followed very often by a vegetable growth, collects on the bottoms of the boats, which, when scraped off, emits a very bad smell, like decomposing fæcal matter, 11,534–37. When first he went to live at Erith, bathing used to take place nearly every day at the end of the pier, but now no bathing goes on, except amongst the "mud-larks." At low water in hot weather the stench at the Corinthian Yacht Club is exceedingly bad, 11,538–9. He looks upon that abundant and general evolution of gas, accompanied by black turbidity in the water as evidence of sewage, because he has seen immense volumes of sewage matter vomited from the northern outfall having exactly the same appearance. Fœtid gas is indisputable evidence of the existence of sewage in the water, 11,541–2. There is a small pipe where sewage is discharged just below Erith Pier. It is above where the bathing used to take place at high water, 11,545–6. From many years experience he is able to distinguish five bad smells, four arising from the chemical works on the banks of the river, and one from the river itself. As to their being noxious he can offer no opinion, but they are undoubtedly obnoxious

Professor RICHARD V. TUSON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

and offensive. He cannot distinguish them all at the same time, but when the wind sets in a certain direction he can distinguish the predominating smell, 11,547–50. At the Corinthian Club House there is an eddy, so that whatever is in the stream is brought back to this particular spot, 11,551–2. The table that Professor Heaton handed in, showing the parts of oxygen absorbed, means absorbed by the permanganate test, 11,555.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He has never analysed the mud in the river, but only smelt it; and, in his opinion, the mud at Erith has increased, especially by the causeway, 11,543–4.

## Mr. LIONEL S. BEALE, M.B., F.R.C.P., F.R.S.

Professor of Principles and Practice of Medicine at King's College.

Fellow of the Royal Microscopical Society.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He received from Dr. Collingridge 25 samples of mud collected from different banks between Gravesend and Chelsea for the purpose of examining them under the microscope, 11,558–61, 11,620, 11,679. He found a practical difficulty in getting a sufficiently thin layer of mud between the glass slides to enable him to see the more important structures, but by taking a piece of mud about as big as a pea, and mixing it with an equal quantity of glycerine, he was able then to examine small portions from different parts of the mass, taking care to separate the coarser particles of sand, so as to get a sufficiently thin layer. This mode is fairly satisfactory, and by it the specimens can be preserved for almost any length of time without their undergoing any change, 11,563–70. He paid more attention to the organic than to the inorganic constituents, and he paid little attention to the particular kind of sand, 11,571. The microscope only roughly gives information as to quantities, and it is only by noticing the number of particles in one field, and then shifting the specimen onwards, and comparing, say, 20 fields, to see whether you meet with one, two, or specimens of the same substance, that you can roughly get the absolute quantities, 11,572–4. He has identified in the mud human excrement itself, portions of muscle, vegetable fibre, starch granules, yellow elastic tissue, and various forms of vegetable tissue, 11,575–6. Yellow elastic tissue is very indigestible, and is not dissolved by the juices of the intestines of the stomach. One form of the yellow elastic tissue comes from the ligament of the neck of a sheep, another comes from the large arteries of the body. Portions of these must almost of necessity adhere to the meat, and he can, he thinks, with tolerable certainty, distinguish between the yellow elastic tissue from the ligament of the neck and that from the ligament of the artery. These matters are constituents of human food, and having passed through the alimentary canal and the sewers, are found in the mud. Their character is so well marked that there is no doubt about them, 11,577–80. Many different forms of vegetable tissue are found, but notably common cabbage. In many cases in the mud near Crossness spiral fibres are found in exactly the same state as those which may be obtained from the fæces of a person who has made a meal of cabbage some time before. The spiral is the least soluble portion; there is nothing in the colour of the spirals indicative of their having passed through the alimentary canal, but in the tissue close to the spiral which gets stained with the yellow matter which is so characteristic of fæces. He hands in drawings illustrative of his evidence, 11,581–4, 11,696–703. These spirals are found in large numbers both at Crossness and at the other places where samples were taken. There are different forms of vegetable spiral fibre, and they resist the gastric juice, and decomposition also. The fibre dissolves and leaves the spirals. They are found in tea leaves also which he has found in the mud. He is able to tell generally where he has found each of these matters, but he has not separated the spiral vessels of different plants, 11,585–94. He has found several specimens of starch granules, some of which come from bread, wheat starch, and rice starch. He has been unable to determine the plants from which some of them came. Probably they had all passed through the alimentary canal. He has found them in the mud from Crossness, Barking, and Gravesend, and, doubtless, had he looked carefully, he could have found

MR. LIONEL S. BEALE, M.B., F.R.S.—*continued.*

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

them elsewhere, 11,595–8. The muscular fibres are the undigested portions of cooked meat, principally beef, he thinks, which has been well cooked, and is not so digestible. The fibres are rendered hard and undergo very little change, probably remaining for months in the same state; they often exhibit delicate transverse markings, which are so characteristic that this tissue can be distinguished from anything else. He can trace the change it has undergone from remaining longer in the river than others; some of the fibres are granular, while those obtained from the sewage itself, or from the banks near the outfall, have a yellow colour, and are very clear and distinct, many containing transverse markings, and several retaining the same appearance which they had when passed, and which depends upon partial digestion having taken place, 11,599–604. In some cases where the markings could not be seen at first, they became visible after having been soaked in glycerine. The muscular fibre is found in many samples besides those from the outfalls, and in various stages of decay, but he cannot say whether that condition of decay depended upon the mere process of digestion or to maceration for a long time on the banks owing to the slow action of the water. He would not be able to say what proportion of the contents, say, of a pint measure, was fæcal matter, but it would be a very small portion; it would be more than $\frac{1}{1000}$th part, 11,605–12, 11,703. He could not distinguish either between the upper or lower part of a sample, but the $\frac{999}{1000}$th parts which are not fæcal matter would be principally sand, 11,613–18, 11,703. He was surprised to find so small a quantity of fæcal matter, because the smell and the appearance of the mud indicated a great deal. The samples were taken in November, December, and January. Those from Crossness smelt very badly; others had hardly any smell. Sometimes there may be a very small quantity of organic matter, but the smell may be very bad, 11,619, 11,621–3, 11,627–8. He has not examined the slimy material upon the banks, but has seen it at Erith in the summer. The samples he received, it will be remembered, were taken in the winter, 11,624–6, 11,694–5, 11,714–16. The relative proportion between the smell and the amount of organic matter varies at different times of the year, and depends upon the rate at which the offensive matter is evolved during the decomposition of the organic matter in the sewage, 11,622, 11,629–30. The yellow elastic tissue will resist decomposition for months, even when immersed in water. It is found in mud taken at Barking, Crossness, Erith, off the "Cornwall," East Greenwich, Trinity Ballast Wharf, &c., 11,631–7. The yellow fæcal masses consist partly of fæcal matter with the remains of undigested food, often with particles of sand which become mixed with them as they are moved up and down with the tide. Being viscid, sticky stuff, it would be likely to combine with the floating mud in suspension in the river. The organic constituents then gradually undergo disintegration and oxidation, 11,638–42. He finds, also, a good deal of fatty matter, speaking microscopically, that is to say; the fatty matter appears partly as oil globules, and partly as crystals, owing to decomposition. Particles of coal and soot, fibres of paper and white fibrous tissues are also found, 11,643–4. He has found products of sewage in all the 25 samples, more or less, the worst being the sample taken from an outfall just below a Trinity ballast wharf at West Ham. Near the outfalls the samples are worse than elsewhere, 11,645–8. A diatom is a low vegetable organism; it is something which is alive, but it has scales composed of silica, which resist decomposition for any conceivable length of time. He has found fragments of diatoms in every specimen of mud. They have been described by Mr. Roper in a paper which appears in the Transactions of the Royal Microscopical Society, new series, volume 2, page 567, 11,649–52. Diatoms are found in fresh water, brackish water, and seawater, and in many instances he can tell from which water the fragments have come. In some mud off the Isle of Dogs 104 species were found by Mr. Roper, 30 being marine, 29 from brackish water, and 45 being of the fresh water species; at Hammersmith 29 were fresh water species out of 43, the remainder being seawater; while at Gravesend, out of 47 specimens, only eight were peculiar to fresh water. The figures show that seawater gets up to Hammersmith, or even to Teddington, 11,653–64. They are very light, and when they die the organic part is dissolved out, leaving the silicous shells,

MR. LIONEL S. BEALE, M.B., F.R.S.—*continued.*

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

fragments of which are found in the mud, 11,665–8. Bacteria are the hundred thousandth part of an inch or less in diameter, and are by no means peculiar to sewage. They are found everywhere in the air and water, and on everything; and in human beings also they exist in every tissue, in the blood, in every part of the body in health and in disease, the frame is full of them. They are alive, or their germs. If the temperature was sufficient for them to grow rapidly, and if time allowed, they would decompose the sewage and render it perfectly innocuous, but that would involve an enormous number and enormous time, and a very thin layer of the organic material spread over an enormous surface. As the sewage is discharged into the river now such a state of things is not likely to take place, and they have no practical effect on the sewage under existing circumstances, 11,669–78. He has not examined the suspended matter in the Thames, but he has examined water with mud in suspension many times, and never saw any organic beings existing in water that would be likely to destroy the suspended matter of sewage, 11,680–3. In the mud he found a large number of desmids and diatoms, and some algæ. He had no opportunity of examining the surface of the mud nor at varying depths (in this inquiry), as it was brought to him in bottles, nor did he make any quantitative examination, 11,684–7, 11,691–3. Hairs of oats were found in the mud, which, together with the spiral vessels, would probably be washed into the Thames with road detritus, 11,688–90. They are not likely to be turned yellow from other causes than from passing through the alimentary canal. The spirals found in peaty water are entirely different to those found in the Thames. These are much larger than the peaty spirals, and are mostly from the common cabbage. Straw spirals are totally different again, and these can all be identified. He would not expect to find many in road detritus, 11,696–702. In passing through the alimentary canal, spirals lose their outer envelope, but by prolonged boiling or prolonged maceration in cold water the same effect is produced, 11,704–7, 11,712–13. The yellow masses which are due to sewage have this distinctive character, that they can be broken up and squeezed between glass, and the yellow matter squeezed out, whereas the yellow matter from vegetables is usually hard and cannot be squeezed, and the yellow matter is distinct. He has frequently seen yellow matter which he should not put down as fæcal. There is no chemical reaction, but you can tell by the eye, 11,708–9. It would be quite impossible to make any mistake about the colour, even if he met with iron in the form of oxide suspended. He has compared the so called fæcal masses in sewage with actual fæcal masses, and they are exactly alike, 11,710. He could detect, without doubt or question, muscular fibre and yellow elastic tissue which has passed through the canal; the other matters, he thinks, not without some doubt, 11,711. He hands in a list of stations where the mud samples were taken from, with the dates; and he also hands in a list of diatoms found in the Thames mud, distinguishing fresh water from sea water. It is taken from a paper by Dr. Bossey, of Red Hill, and published in the proceedings of the Holmesdale Natural History Club, 11,716.

## MR. CHARLES ERNEST BRUGES.

Assistant to Mr. Baldwin Latham.

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—On the 14th and 22nd of September 1882 he went to Teddington to take samples of the water. The diagram he produces represents the positions at which he took the samples A, B, C, D, and E, and the river for that purpose was divided into six sections, 11,717–21. At each station he took samples a foot below the surface, and 20 feet below the surface, or as near to it as he could; but in no case was it taken below that depth. The bottles were cleansed chemically before he went to Teddington, and before taking the samples they were washed twice at least, sometimes more frequently In the case of the surface samples the bottles were lowered into the water with the stoppers in. They were then taken out, and replaced before the bottle was taken out of the water. In taking the deep samples, the bottles were lowered with a weight attached to them, and the neck tilted up stream to prevent any

## Mr. CHARLES ERNEST BRUGES—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

mud getting in. The stopper was then removed by means of a string, and the bottle was then drawn up, and the stopper put in before it reached the surface. In no case was any mud disturbed, and when the sample is said to have been taken at the bottom it was really taken eight or nine inches from the bottom to avoid disturbing the mud. As a matter of fact there is no mud at Teddington, it is a hard bottom, 11,721–32.

## Mr. FRANK JOB SHORT.

Assistant to Mr. Baldwin Latham.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He took certain samples of water at Deptford, but only at three stations across the river. The diagram produced represents the place where they were taken and how it was done, and it corresponds with Professor Way's description. He took the samples in the same manner, and in exactly the same way as Mr. C. E. Bruges, 11,733–9. They were taken at high water and at low water, the river being divided into four parts, 11,740–1. He found out when it was high or low water by mooring his boat to a dolphin of the pier, and then scratched marks on the piles until the water rose or lowered no more in the case of high and low water respectively. There was then a short period of slack water, and the samples were taken during that time, 11,742. In the middle of the river the samples were taken 20 feet below the surface, and at the other stations they were taken at a foot, or a foot and a half from the bottom. The bottle had a heavy weight attached to it, and was lowered quietly on to the mud; the stopper was then removed by means of a string and the sample was taken. The time occupied in taking the samples was a quarter of an hour, 11,743–51.

## PROFESSOR W. H. CORFIELD, M.D., F.R.C.P.

Professor of Hygiene at University College, and an Examiner for Sanatary Science Certificate at Cambridge.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—On the 16th October 1878, shortly after the sinking of the "Princess Alice," he examined the condition of the lower Thames, and the outfalls of the metropolitan sewers. The outfalls at Barking and Crossness were both discharging at the time of his inspection, and the sewage was flowing up steam, 11,761–6. He followed the sewage in a boat for three quarters of a mile, and it was distinctly marked by the floating material upon the surface of the water. The stench was very bad indeed at both the outfalls, 11,767–71. He took samples and specimens in several parts of the river near the outfalls, which have been deposited in the Parkes Museum of Hygiene in Margaret Street, Regent Street, 11,772–3. One sample was taken in mid-stream off South Woolwich about 12 o'clock, and another at Barking, about 100 yards above the outfall, at 5 p.m., 11,774–6. The sample collected off Woolwich was a highly polluted water, and contained ·20 parts in 100,000 parts of albuminoid ammonia, or one-tenth of the quantity in sewage. It also contained seven parts per 100,000 of suspended matter, of which 80 per cent. were fixed and 20 per cent. were volatile. The sample collected at the Barking outfall contained about 4·50 parts per 100,000 parts of saline ammonia, and 14·65 parts of suspended matter, of which 40 per cent. were fixed, and 60 per cent. were volatile, 11,777–81. These samples, when compared, give an idea of the condition of the river at the two places, 11,782. He inquired also into the circumstances of some cases of illness due to the immersion of people in the Thames at the time of the accident to the "Princess Alice." He neither saw the people nor their clothes, but he inquired of their friends and the medical men, 11,786–90. He describes in detail the particulars of the different cases, which were considered to be in some instances pneumonia, accompanied with diarrhœa, in others actual typhoid fever. In one case a medical man was of opinion that the patient was not suffering from typhoid fever, but it is a significant fact that the nurse took typhoid fever and died from it. There is no doubt these illnesses were due to immersion and the water swallowed by the people, 11,790–2.

## Professor W. H. CORFIELD—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He has inspected the mud at various places in the river, but he did not take any away with him. In most places it was black and very foul, and it was for the most part very slimy, 11,783–5.

Effect upon Health in the Neighbourhood of the Main Outfalls.—For the years 1871 to 1881 inclusive, he has examined the Registrar-General's Returns to see if the state of the river produces any effect upon the health of the population upon the banks of the Lower Thames, between London Bridge and the Medway, and he has compiled some tables from those Returns, which he now hands in, 11,793–8, 11,809. Table I. contains the deaths, especially from zymotic diseases, for each quarter during the 11 years in the following districts:—Aldgate, St. Paul's, Stepney, Poplar, West Ham, Barking Town, Hornchurch, and Orsett, on the north side of the Thames. Table II. gives similar details for the districts of St. Olave, Southwark, Greenwich, Woolwich, Bexley, Dartford, Northfleet, Gravesend, and Hoo, on the south side of the Thames. Table III. shows the annual results for the districts on the north, and Table IV. for the south side of the Thames. Tables V. and VI. show the average annual number of deaths from zymotic diseases in each of the districts on the north and south respectively, 11,709–808. Tables VII. and VIII. give the average death-rate from each of the zymotic diseases, and from them altogether the death-rate per 1,000. In those tables are included London and the eastern and south-eastern registration divisions of England, in which the districts or sub-districts are. The counties, therefore, are Essex, Suffolk, and Norfolk on the north, and Surrey, Kent, Sussex, Hampshire, and Berkshire on the south, 11,809–12. Table IX. and X. show the density of the population in 1871 and 1881 on both sides of the Thames, including London and the two registration districts, 11,813–4. Table XI. shows the corresponding figures from Dagenham. This he has taken separately because he found it was included in the Romford sub-district, which includes the town of Romford as well as Barking Town and Hornchurch. Dagenham is included in that part of the sub-district which takes in Romford Town; so he obtained the figures from local sources, and gives Dagenham by itself, 11,815–17, 11,874–77, Tables XII. and XIII. give similar statistics for Rochford on the north (including the towns of Southend and Raleigh), and the two districts of Sheppey and Blean on the south, 11,817–20. Table VII shows that the average zymotic death-rate upon the north side of the Thames in six districts is either above, or very nearly approaches, what it is in London. In the first four districts it is higher than the death-rate in London; and in the last four it is decidedly higher than the death-rate in the eastern registration district with the exception of Hornchurch, 11,821–31, 11,929–32. The deaths from measles, scarlet fever, and diarrhœa, in the northern riparian districts are very largely in excess of those in the eastern registration district. He has very little doubt that one cause of the increased general zymotic death-rate along the banks of the river on both sides, and of the special increase in certain zymotic diseases, most notably scarlet fever, is the condition of the river. He has no doubt that the foul condition of the river has an effect upon the population living upon its banks. The statistics lead him to the conclusion that the high zymotic death-rate is partly due to the sewage flowing down the river, and it would be lessened if nothing but pure water flowed down the stream, 11,832–46. On the south side of the river the general zymotic death-rate is higher in all the districts than it is in the general south-eastern division. Upon the north side of the river, east of the Medway, the zymotic death-rate is a little below that of the eastern registration district; upon the south side the death-rate of Sheppey is decidedly less, and the death-rate of Blean (which is a little further on) is a little less than that of the south-eastern registration district generally. It is due to the pure sea breezes, and to the chalk, which is healthier, 11,847–52. The death-rate for measles, scarlet fever, and diarrhœa on the south is decidedly higher, with the exception of Gravesend, for measles, than the corresponding death-rate for the south-eastern registration district. He makes a further exception in the case of Hoo, where every death seems to be put down to "fever," not scarlet fever, of which there is scarcely any, 11,853–57. On the north side the deaths from zymotic diseases

PROFESSOR W. H. CORFIELD—*continued.*

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS—*continued.*

exceeds the average for London, and on the south side there is a similar excess, with the exception of St. Olave, Southwark, 11,858–60, 11,929–33. In the other cases the death-rate exceeds that of the districts of which they form a part. At Bexley the actual majority of the population is in places at a considerable distance from the river, and while the zymotic death-rate there is about equal to the death-rate of the south-eastern division generally, the death-rate from scarlet fever is very much higher than it is in the division, and very nearly approaches that of London, 11,861. The density of population in Orsett and Northfleet on the north and south sides of the river respectively is almost exactly the same as for their respective registration divisions, and the death-rate for zymotic diseases is decidedly greater in the case of Orsett, and considerably greater in the case of Northfleet, than it is in their divisions. In Northfleet it is higher than in any other place below Greenwich, 10,862–70. By taking the statistics separately for 10 years and averaging them, he has eliminated any possible irregularities in the tables which might vitiate the smaller induction, 10,871–2. He has compared the zymotic death-rates in the districts bordering upon the north side of the Thames with the zymotic death-rates of the general districts of the eastern registration division of which they form a part; then he compared the death-rate in the districts near the Thames with those in the districts lower down the Thames. He has also compared the death-rates of the places higher up the Thames with the death-rate of the districts of Rochford on the north side, and the island of Sheppey and Blean on the south side, 11,878–85. The average death-rate from zymotic diseases in Rochford for 10 years is the same as that for the eastern registration district, and is, therefore, lower than in the riparian sub-districts higher up the river. The scarlet fever death-rate is very much lower than in any of the districts up the Thames, and these healthy places in the eastern district bring down the death-rate as against the towns. Scarlet fever is a disease which is shown to be specially prevalent in those districts near to the banks of the Thames above the Medway, 11,885–94, 12,023–4, 12,035–8. He has not noticed that the registration of scarlet fever as measles in Rochford district has affected the results as shown in his tables. Such a defective registration is possible. Combining the two, the death-rate in the eastern registration division is ·57, and in Rochford alone ·44, 11,895. He has not got the details of Grays and Purfleet separately; they are included in Orsett, and the zymotic death-rate in that district is certainly higher than in the eastern division, 11,896–8. Sheppey is divided into Minster and Eastchurch, and Minster stands on high ground, 11,899–900. The zymotic death-rate in Sheppey has averaged during the last 10 years 1·90 as against 2·38 in the south-eastern registration division generally. The influence of the sewage has died out before reaching Sheppey, hence the low death-rate. The same remark applies to Blean also. Blean is a district beyond Sheppey, and includes Herne and Whitstable, 11,901–2, 10,904. In scarlet fever the rate in both these districts is less than in the south-eastern registration district, and decidedly less than in any of the districts upon the south of the Thames, with the exception of Hoo, where everything is registered as fever. The soil of Sheppey is practically all tertiary clays or post-tertiary alluvial deposits, which extends to all those districts. The chalk is not reached until you come to Canterbury, 11,903, 11,905–7. In all his tables he lays special stress upon scarlet fever as an indication of the health of the population upon the banks of the Thames, 11,908–9, 12,023–4. Apart from any other element, the density of the population has a great deal to do with the deaths from zymotic diseases, consequently the death-rate in any of the districts of London may be expected to be higher than country districts, though he could point out a number of cases of less zymotic disease with a denser population, 11,910–17, 12,017–22. The death-rate in those districts inhabited by the poorer classes, such as the East End of London, would be higher than in those parts where the better and higher classes principally reside, and as a matter of fact the population of the East End is denser and poorer than the West End. These two causes, therefore, both operate to raise the zymotic death-rate in the East End above the average, and this applies to all Eastern London, whether riverine or not (*see* Tables IX. and X.), 11,918–28. The zymotic death-rate of Barking and West Ham is very little below the death-rate of London, whereas their density is enormously less, 11,933–34. The fair way to compare the death-rates of the riparian districts is, not with the death-rate of London, but with the death-rate of the registration divisions to which they belong. St. Olave's may fairly be compared with London, Greenwich with London or the registration division. Greenwich Park lowers the rate of Greenwich by adding to the acreage without increasing the density of the population, 11,935–44. The towns in the Rochford, Sheppey, and Blaen districts are estuarian places, and the density of the population is very thin. So it is fair to compare them with the death-rates of the registration districts, 11,945–7. In Tables VII. and VIII. the population of the selected districts for the most part is near the river, although in a few cases it is situated away from it. He hands in a map on which the districts have been roughly marked out. He is unable to say how far the deleterious influence of the Thames can be conceived to extend. Although he is told that the sewage can be smelt three miles away from the river, he has never smelt it himself so far away, 11,948–9, 11,954–5. His districts begin at London Bridge, and the City is, therefore, not included in them. Stepney, which is in Limehouse, runs back about a mile from the river; Poplar extends 2½ miles back; Barking Town (which means the district and not merely the town) goes back rather less than 2½ miles; the death-rate is 3·12 as against 3·84 for London generally, and 2·38 for the eastern registration division, 11,950–3, 11,955–8. The population of West Ham is mostly away from the river, the docks intervening between it and the river. The northern outfall is included in this district, 11,959–63. Although Barking has a remarkably low average of zymotic disease, yet it has an enormously high death-rate from scarlet fever, higher than the east of London and the other places, 11,964. The report of Mr. Rawlinson in 1869 on the alleged nuisance and injury to health from the discharge of sewage at Barking, which he considered were not sufficiently established, precludes Barking from being used as a criterion to a certain extent, 11,964–8. He has included St. James's, Bermondsey, in his tables as well as St. Olave's, Southwark, St. John's, Horsleydown, and Rotherhithe, all being riparian, 11,969–70. He has no doubt that the death-rates of the floating small-pox hospital has been included in the Greenwich district zymotic death-rate. He has not eliminated them from his tables, which were taken from the quarterly returns of the Registrar General. He found it was impossible to do it. The same remark applies to St. Olave's district in which Guy's Hospital is situated, and to the other districts also. There are hospitals for zymotic diseases in several parts of London, but they are not situated specially about the river, 11,971–87, 12,014–6. Patients suffering from certain zymotic diseases, such as enteric fever and diphtheria, and in a few cases scarlet fever, are admitted to the general hospitals; but there are special fever hospitals at Homerton and Stockwell, and there is a small-pox hospital at Deptford, 11,988–93. The rate of zymotic disease in the upper part of the metropolis has fallen since the sewage has been taken lower down the river, 11,994–7. Most of the population of Woolwich is within a mile of the river, and the farthest part is about three miles from the river. The Bexley district runs back about five miles, and the Dartford district goes back to a similar distance. The farthest point in the Northfleet district is about 7½ miles from the river, 11,998–12,003. He has included in these districts, or in parts of the sub-districts which he has been able to take, nothing but what is included in the sub-district of the Registrar-General. No doubt the better plan would have been to draw a line from the river to the point where the influence of the river terminates, and ascertain what the death-rate in that portion would be; but it was impracticable, 12,004–5. Deducting the deaths from small-pox, the zymotic death-rate of Greenwich is then lower than the other districts, 12,006–7, 12,014. The high death-rate in Hoe he attributes to diarrhœa, which is caused by drinking impure water. As he explained before, he does not attach much importance to the death-rate as everything is put down to "fever." There is no other way of accounting for the fever death-rate than that,

PROFESSOR W. H. CORFIELD—*continued.*

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS—*continued.*

12,008–13. On the south side of the river the density of the population in all the districts, except St. Olave's, is less than the density in London, while the scarlet fever death-rate in Gravesend, Woolwich, and Northfleet is higher than, and Greenwich and Dartford nearly as high as, that in London, 12,017–22. He presents his tables, firstly, as facts to be considered, and, secondly, that in his opinion the emanations from the river must have some influence upon the death-rate. He thinks the sewage in the river is one of the principle causes operating upon the zymotic diseases upon both sides of the river. He has no data for eliminating other causes in forming this opinion, and can only point out that some of the districts, which have only places near the river, give examples of very high death-rates. Dagenham, for instance, which is close to the river, has a very high zymotic death-rate, and an exceedingly high scarlet fever death-rate. It is low and marshy, but that has not much to do with scarlet fever, 12,027–33. He has not had time to obtain statistics of other riverine districts where no sewage flows into the river for the purpose of comparison with the Thames, 12,034.

## MR. BENJAMIN BROWNING, L.R.C.P. Lond., S.Sc.C. Edin., F.C.S., &c.

Medical Officer of Health to the Parish of Rotherhithe, and Surgeon to a Sub-division of the M. Division of Metropolitan Police, and to a Sub-division of the Thames Police.

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—He has lived at Rotherhithe for more than seven years, and during that time has paid a good deal of attention to the condition of the Thames. He has examined the water and mud of the river at different times, and on several occasions has taken samples of the water during the past five years for the purpose of examining them chemically and microscopically for his own information, 12,039–50. The first conclusion to which he has come with regard to the effect of sewage as it is poured into the river is that a considerable portion of the sewage which is discharged into the river at Crossness and Barking is not carried down to the sea directly, but is brought up the river at least as high as Limehouse, if not higher. The second conclusion is that whilst the sewage is thus retained in the river it undergoes decomposition and becomes injurious to health; and the third conclusion is that the number of cases of various illness, such as fever, especially typhoid fever, scarlatina, various throat affections, general malaise, and sometimes diphtheria, as well as some cases of diarrhœa are directly attributable to those emanations from this decomposed sewage. He has satisfied himself of this after attending patients, and going out, in the case of the Thames Police especially, by day and by night at the same time of the tide to which they said they had been exposed to those emanations, 12,057–9. He has proved that the sewage ascends the river, by the eye, smell, and touch, and also by microscopical and chemical evidence, 12,077. In 1878 there was in Rotherhithe a stagnant piece of water known as the "mill-dam," which was in a very offensive condition. That has been piped, drained, and put in repair, and now does not exist. The numerous privies and drains, which at that time discharged into the Thames, have since been cut off, 12,171–5. He does not think they were in existence in 1881, as stated by Dr. Collingridge in his report. If they were they had been opened again, though he could not find any trace of them when he specially examined the foreshore of Rotherhithe in that year, 12,199–208. The only nuisance left is the Thames, which, he thinks, is the chief nuisance, 12,209. Most of the pollution of the river is brought up from the outfalls on the young flood. The river is more polluted then than at high-water, 12,148–50.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—He has taken specimens of the mud near the outfalls, and as high up as Wapping, and also at the Surrey Commercial Docks. He found it black and very fœtid, and to the best of his knowledge and microscopical observation, it contained evidence of sewage, 12,078–81.

MR. BENJAMIN BROWNING—*continued.*

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—He has under his care 50 officers and men of the Thames Police, besides a large number of land police, and in addition he has the medical care of a number of clubs amounting to between 600 and 700 workmen in all. They are composed for the most part of waterside people, bargees, watermen, lightermen, and boatmen. Having in some cases investigated the statements of a number of people who attributed their illness to the smells from the river, he has come to the conclusion that a considerable portion of the sewage discharged at both the main outfalls is not carried down to the sea directly, but is brought up the river at least as far as Limehouse, if not higher; that whilst the sewage is thus retained in the river it undergoes decomposition, and becomes very injurious to health; and that the number of cases of various illness, such as fever, typhoid fever especially, scarlatina, various throat affections, general malaise, and sometimes diphtheria, as well as some cases of diarrhœa are directly attributable to these emanations from this decomposed sewage. He has satisfied himself of that after attending the patients and going out, especially in the case of the Thames Police, by day and night at the same time of tide to which they said they had been exposed to those emanations, 12,051–9, The members of the clubs, when ill, are entitled to sick pay, and he investigates their case. If they wish it, irrespective of his own judgment, he puts them on the sick list. With the police it is different. They are men in the prime of life, carefully selected, of good physique generally, and with good hygienic surroundings in their houses, most of which he has personally inspected, and they are less likely than others to be affected by surrounding circumstances. There is no temptation on their part to pretend to be ill, because a considerable portion of their pay is stopped when they are ill, 12,060–7. Out of 146 cases of illness in five years amongst the 50 men of the Thames Police, he has had 18 cases of various forms of illness which to the best of his judgment, and in the belief of the men themselves, were attributable to the emanations of the river to which they were exposed when on duty, between London Bridge and Greenwich, and also to Barking, 12,068–71, 12,129–42. There is much more sickness amongst them than amongst the land police, with the same conditions as to pay and hygienic surroundings. The proportion, roughly speaking, is about two to one. He does not refer to exposure to the weather. All such cases he has eliminated from his figures, 12,072–6, 12,116–23. The health of his patients varies according to the season of the year, and on comparing his riverside patients with those who work away from the river, he finds the latter do not suffer from what he terms "riverine" complaints. The nature of these complaints is a special form of sore throat, a great deal of malaise and languor, a sort of ill-defined fever, and more or less diarrhœa. He has found diphtheria distinctly attributable to it, and he has traced cases of typhoid fever to drinking Thames water from alongside ships, 12,082–6, 12,204–6. The average zymotic death-rate in Rotherhithe for the last ten years has been 3·83 per 1,000, which is higher than many other corresponding riverine districts, but below the average of London. This may be due to his removing a great many cases of fever to hospitals outside of his parish, 12,087–96. He has nothing to do with the "Royalist," but he has had men transferred from the ship to his district, who have complained of the situation, 12,098–103. Last year he had only two cases of illness in the river police which were due to the river, one of which was blood poisoning followed by an abscess. During five years he had only five cases of blood poisoning, and one of them was dyspepsia. Blood poisoning, as a rule, does affect strong healthy men, their *vis vitæ* enables them to escape in many instances, even when exposed to its influencing causes, 12,104–13, 12,124–200–203. He does not remember a single case of blood poisoning amongst the land police, 12,114–5. The term "malaise" is difficult to define, but he can best describe its meaning by the expression "all-"overishness," 12,125–6. There are not many factories in Rotherhithe, and those in Bermondsey are a long way from the river, 12,127–8. In addition to the 18 cases which he cannot positively put down as due to the river, there were about double that number of doubtful cases. He shows one case in his extracts which was due to derangement of the functions of the stomach and liver, and was attributable to the emanations from the river. As that man was under his care and treatment for the same ailment on six or seven

## Mr. BENJAMIN BROWNING—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

different occasions, it ought to appear as six or seven cases instead of one. Another man suffered from the same complaint, but his case was so serious, and lasted so long, that he was discharged from the service in consequence, 12,132–4, 12,200–3. The cases of diarrhœa which occur in the summer he attributes to the river on the men's own statements, and also from his knowledge of their diet; he has not put down a single case of diarrhœa unless the man who suffered from it was, or professed to be, a total abstainer, 12,135–9. A case of gastritis he put down to the river, as the man worked in the lower part of the Thames at low tide, and complained of the smell from the mud. He also was a teetotaller, 12,140–2. Those men who work in the docks and not on the river are free from those stomach affections, although the docks are filled with the water from the river. He concludes that the same emanations do not rise from the water in the docks, 12,143–7. None of the deaths from typhoid fever occurred in the streets or district of Rotherhithe contiguous to the river, except in Rotherhithe Street, which is parallel to the river, and always has had its fair share of mortality of all sorts, 12,151–3. In 1856 Rotherhithe was supposed to be one of the most insalubrious suburban districts, being almost entirely unsewered, marshy, with a scanty water supply, and that so contaminated as to be usually refused by horses. The marsh has now been done away with, having been drained and built over gradually until the present time. The "corrected" death rate is 18·8 per 1,000 now, and so far as that is concerned, Rotherhithe is not insalubrious, 12,154–70. In 1878 a horrible and dangerous nuisance was caused by a man named Judd, who collected, to an enormous extent, fish refuse for manure making in several arches of the South-Eastern Railway. This has been put down, and the man is now in prison, 12,176–8. The "corrected" death-rate of Rotherhithe for 1881 is 18·7. He has no statistics as to the sickness rate, because so much sickness, especially zymotic sickness, is very carefully concealed, and consequently any statement he might prepare on the subject would be perfectly valueless, 12,179–82. His annual reports to the vestry do not refer to any illness being attributable to the river, because the vestry declines to go into matters which pertain to other bodies. He therefore limits himself to those causes which are under the control of the vestry, 12,183–97.

## Mr. WILLIAM HICKS,

Keeper of the Port Sanitary Authority's Hospital Ship "Rhin."

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—The hospital ship "Rhin" is anchored one mile below Gravesend, and on the 14th and 22nd September 1882 he took three samples of water each day, as nearly as possible in the same places, and under precisely the same conditions. The samples were labelled North Shore, Middle Channel, and South Shore. He took the first sample alongside of the ship about a quarter of a mile from the shore, one a foot below the surface, and one 23 feet below the surface. He then took two samples in mid-channel at high and at low-water at the same depths (mid-channel being half a mile from the shore), and he obtained two samples on the north side, a quarter of a mile from the shore. When unable to take the samples 23 feet below the surface he took it at 20 feet below, 12,292–313. He knew when it was high and low-water by the swinging of the ship at the ebb and flow of the tide. He was about 20 to 30 minutes taking the samples, roughly speaking, 12,314–25. The mode in which he took the samples was, first, he put the bottle into a bag with a weight attached, and lowered it to the required depth. He removed the stopper from the bottle by means of a line, allowed the bottle to fill, and then hauled it to the surface. On no occasion did he touch the bottom, because his ship draws 17 feet of water, 12,326–37.

## Mr. WALTER BOUND,

Pier Master at Erith.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—On the 14th September 1882 he took some samples of water from the Thames at Erith in four different places across the river at high and at low water, in a line from the pier to the Red House on the north shore. He divided the

## Mr. WALTER BOUND—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

distance across the river, as nearly as he could, into equal parts, 12,338–45. When he had collected all his samples in the boat he corked and labelled them, and then took them ashore. It took him a little more than half an hour to take the samples. He also took some more samples on the 30th November, and again on and after the 10th October, for some days; he took some samples from off the end of the pier, 12,346–55, 12,357. To obtain the deep samples he had a line fixed to a lead, and a mark to show 20 feet. He also had a line to the stopper, which he drew out when the bottle was at the proper depth and filled the bottle, 12,356. He took two samples at each place, one just below the surface, and the other at 20 feet below. He did not touch the mud on any occasion, and at low water he took the same places as at high water, 12,358–62.

## Mr. WILLIAM BRADLEY,

Lighthouse Keeper at the Pier Head, Southend.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—By direction of the Port Sanitary Authority he took samples of the Thames water at Southend on the 14th and 22nd September, and the 30th November 1882, at high and low water, 12,363–7. On the first two days he took eight samples at each tide, beginning at half a mile from the pier, and then at each successive half mile till he reached two miles; one sample he took a foot below the surface, and the other at a depth of 20 feet. He took none on the north side of the river, 12,368–72, 12,381–3. To obtain the deep samples he made the bottle fast to a lead-line, and attached a string to the stopper. He then lowered the bottle to the requisite depth, withdrew the stopper, and in two or three minutes pulled up the bottle, which he re-corked and labelled. It took him about an hour to collect the samples and bring them ashore, 12,373–80.

## Mr. CHARLES WOOD,

Superintendent of the Wreck and Mooring Service of the Thames Conservancy.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He has been in the service of the Thames Conservancy since 1869, and during that time he has been engaged in raising wrecks in the Thames. He had 20 years' experience before that, 12,384–9, 12,432–3. In the course of that time he has found considerable difference in the condition of the wrecks, owing to the quantity of mud in the bed of the river, 12,390–91. In 1861 a vessel was sunk in Halfway Reach, and when raised she was put on the shore above Dagenham Dock about a week later. It was hard, clean shingle, and the little mud in the ship had flowed into her from settlement. Twenty years after (in November last), another vessel, after being in collision, was run ashore at the same place, and there were nine feet of mud on the shore. The surface was white, but underneath it was black mud, all sewage, 12,392–407, 14,434–8. Last month he raised two barges in Northfleet Hope, which had been in the water a week, and five days, respectively. They had a large quantity of loose white mud in them, far more than he found in 1861, 12,408–14, 12,435. There is a great deal of black mud in Northfleet Hope which smells. It is quite unlike ordinary Thames mud, and the chains for raising wrecks get smothered with it. The same sort of mud is found in Halfway Reach and Gravesend Reach, 12,415–21. In former years the bed of the river used to be clay in some parts, and gravel in others. There was none of this black mud, 12,422–4. Above Greenwich the water is brighter; there is less mud since the opening of the outfalls, but it is much worse than it used to be below Greenwich. From Woolwich to Sea Reach the water is very bad, and the worst parts are Gravesend Reach and Lower Hope, and also Jenningtree Point, where the bottom has grown up 10 feet within the last few years. Sponges, rags, and guts, &c. are found to a very great extent in the mud there. A ship could be loaded with sponges and rags at that point, 12,425–31. In former times there used to be a deposit of mud in the Upper Pool, perhaps three or four feet deep. It was totally different to the black mud which is now met with, and it has been washed away from the pool by the large quantity of land water which has come down the river of late years. It will in all probability accumulate there again, 12,439–49.

## Mr. GEORGE CUSTANCE,

Formerly Pier Master at Erith.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He was pier master at Erith for 19 years, and left in October 1881. He is now 65 years of age, and knows the condition of the river at Erith well, 12,450–5. He remembers the outfalls being opened at Barking and Crossness, and at Woolwich prior to the opening of the outfalls, the water was used for drinking purposes, and at Erith the river was clear, wholesome, and healthy, and was used for cleaning purposes. "It was beautiful water." Now the condition of the river is very bad and cannot be used for cleaning decks or scouring at half ebb, 12,456–62. There is a sewer which goes out a long distance away from the pier to about 400 feet below low-water mark, but that does not affect the state of the river. He has not noticed that this sewer is imperfect in its condition, 12,470–2. When he was in the Steam Reserve at Woolwich in 1847 he used to drink the Thames water daily, but it has long been unfit for drinking purposes, 12,478–80, 12,489–94.

Popular Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—There used to be a small reservoir at Mr. Beadle's coal wharf to wash away the mud, but since the opening of the outfalls it has been enlarged to wash away the accumulation of mud from the outfalls. There never was any tendency for the mud to deposit there, 12,481–7.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He has had occasion to complain very much of the smell of the river, which gave him great headache and diarrhœa. It used also to affect the men and produce headache and stomach-ache from the vapour and smell arising from the mud. He has known people land upon the pier and turn back at once on account of the smell, 12,463–9. The smell is worst in the summer time, and he has had to knock off work for a day or two at a time on account of it, and place himself under medical treatment, 12,473–7.

## Sir JOSEPH WILLIAM BAZALGETTE, C.B.,

Engineer to the Metropolitan Board of Works.

Description of the Main Drainage Works, and Capacity of the Drainage System as compared with the Demands upon it; Influence of this on the Storm Discharges.—Before describing the works which have been carried out for the interception of the sewage from the river, he wishes to refer shortly to what has rendered these works necessary. The Thames is situated in the bottom of the London basin, which is bounded on the north by Hampstead and Highgate, and on the south, though more distant, by the Surrey hills. The rain water from the hills flows into that basin through the riverets and brooks, the leading ones on the north being the Eel Brook, the Ranelagh, the Stamford Brook, and the Brook Green sewer, the King's Scholar Pond, the Fleet, the London Bridge sewer, the Irongate sewer, and the Ratcliffe Highway sewer; on the south, the Falcon Brook, the Effra, the Duffield, the Earl, the Great St. John's, and the Ravensbourne. (This last is now converted into a sewer and is covered in.) These riverets flowed from the high ground down into the low ground, which is considerably below the level of high water, and before it was embanked the tide flowed up those streams and flooded the low lying ground. At that time (prior to 1847) it was penal to discharge any sewage into these brooks, 1–3, 36–7. Before the general introduction of water-closets, all the sewage went into cesspools, and continued to do so until the water-closet system rendered it impossible, when overflows from the cesspools into the sewers or brooks were for the first time permitted. These cesspools became so numerous that they were found to be a source of disease, and in 1847 the sewer system was introduced, and about 30,000 cesspools were destroyed. These open sewers were then covered in, and they discharged their contents into the Thames at low water, the worst period, for sanitary reasons, because the sectional area of the river at low-water is very much smaller than at high-water, and secondly, because the sewage, instead of being carried away by the ebb tide from London, was carried from low-water to high-water up the river, 3. He has prepared, and hands in, a section of the Thames at London Bridge showing the sectional area of the water at high and low-water, 3–5. Putting a "float" into the river at high-water, as compared with low-water, makes a difference of about 12

## Sir JOSEPH W. BAZALGETTE—*continued.*

Description of the Main Drainage Works, and Capacity of the Drainage System as compared with the Demands upon it; Influence of this on the Storm Discharges—*continued.*

miles, so if a float be put in the river at low-water, say at 12 miles below London Bridge, it will upon an average of tides float up to London Bridge, so the sewage having been put into the river at low-water for some years, and flowing up, caused a nuisance which led to the formation of the Metropolitan Board of Works in 1855, 5–8. Their first duty was how to overcome this difficulty, and the difficulty was very greatly increased, from the fact that whilst the sewage was of comparatively small quantity, and tolerably uniform, the rainfall was a very excessive and a very variable quantity, amounting sometimes to an inch, or even to two or three inches in an hour. As much as four inches have been known to fall in some parts of London. Now the maximum flow of the whole sewage of London does not amount to $\frac{1}{100}$th of an inch per hour in quantity over the whole area, 8–9. This question has been and still continues to be a great difficulty. To separate the rain water from the sewage would have involved the redraining of all the houses in London, at a cost of 8,000,000*l.*, and the construction of separate sewers at a still further expense, to say nothing of the very powerful resistance to such a proposal. It was therefore considered impracticable, 9, 188–93. As there are only 14 to 21 days in the year on which the rainfall exceeds a quarter of an inch in 24 hours, it was considered possible to divert from the present sewers, which discharged into the river, the whole of the sewage and a quantity equal to a quarter of an inch of rain running off with it. This was done by constructing lines of sewers at right angles (or nearly so) to this main valley sewer, which ran from the high ground down to the river, and began by intercepting it at the upper points, so as to carry the sewage as much as possible to high-water by gravitation, to save pumping. In this way the high level sewer was commenced at Highgate and Hampstead, passing through Hackney and Stratford to Barking Creek. It intercepts the sewage from an area of 10 miles, and beginning by being four feet in diameter it increases at the lower end to 9 feet 6 inches by 12 feet. Its length is 7 miles, and it has a fall of 75 feet to the mile at the upper end and 4 feet at the lower end. It takes nothing from below it, 9–11. The sizes of the intercepting sewers are graduated to take the calculated quantity of sewage and rainfall whenever they are filled; near the top of them is a long weir, over which the surplus water flows (when the rain exceeds the normal quantity) into the main sewer at a lower point, and this is the principle upon which the storm waters are allowed to pass from the intercepting sewers into the river, 11–12. The middle level sewer commences at Kensal Green, passing through Oxford Street and nearly in a direct line down to the high level sewer at Bow, where the two run parallel, but distinct, having the means of communication, if desired, to equalize the flow at the outfall. It is 4 feet 6 inches by 3 feet at the upper end, and increases to 10 feet 6 inches in diameter at the lower end. Its length is 11½ miles, with a fall from 17½ feet down to 2 feet in a mile. The low level sewer commences at the pumping station, and passes through Pimlico, along the Victoria Embankment, through the City and Stepney to the Abbey Mills pumping station. There it is lifted to the level of the two other sewers, and the three pass by parallel sewers down to the reservoir at Barking. It drains an area of about 11 square miles; it is 12½ miles long; its diameter increases from 6 feet 9 inches to 10 feet 6 inches, and its inclination varies from 3 feet to 2 feet per mile, 13–15, 12,746–65, 12,785–93. The area beyond, containing Chelsea, Hammersmith, and Acton, which is termed the "Western Division," has a separate set of sewers, which pass from Hammersmith through Chelsea to Pimlico, where the sewage is lifted in the low level sewer, 15. The whole area, both north and south, for which the Metropolitan Board of Works has to provide, contains about 117 square miles. Upon the north side 53 square miles, and on the south 66 square miles, 16–19, 92–93. On the south side the high level sewer has a main line and a high level branch, which together intercept the sewage from 20 square miles. The main sewer commences at Clapham, passing through Brixton to Deptford Creek, where it is joined by the branch line which starts at Dulwich and goes through Peckham. These pass under the Creek and have a storm outlet into the Creek. The southern

SIR JOSEPH W. BAZALGETTE—*continued.*

DESCRIPTION OF THE MAIN DRAINAGE WORKS, AND CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

high level sewer varies from 4 feet 6 inches by 3 feet to two parallel sewers, each of them 10 feet 6 inches wide by 10 feet 6 inches high, with upright sides and a crown. The inclination varies from 30 feet to 2½ feet per mile, and its length is 13 miles, 19–22. The low level sewer commences at Putney and runs through Wandsworth, Battersea, Nine Elms, and Kennington down to Deptford Creek. The whole of that district is very flat, and the sewer is very flat, and that is the reason why it is not carried along the bank of the river. The outfall sewer is 11 feet 6 inches in diameter, with a fall of 2 feet per mile, 22. At Crossness there is a pumping station with a lift from 22 to 33 feet, according to the state of the tide and the condition of the sewage, with a 500 horse-power pump, and an auxiliary pump of 500 horse-power, which is used in time of storm. At Deptford there is a lift from the low level sewer into the outfall sewer of 18 feet, with engines amounting to 500 horse-power. At the banks of the Effra there is 200 horse-power provided for lifting the storm waters into the river in times of heavy storms when they are penned up by the tide, and there is another at Falcon Brook of the same power, which lifts from 6 feet to 12 feet. At Abbey Mills the lift from the low level sewer into the outfall sewer is 36 feet, with 1,140 horse-power; and the western district is lifted into the low level sewer 18 feet, with an auxiliary, in times of heavy rain, of 120 horse-power, making a grand total of 3,520 horse-power, nominal, 22–4, 136–40, 207. The Metropolitan Board of Works has the charge of the main intercepting sewers, and also of the main storm sewers (called main sewers in Schedule D. of the Act of 1855), and the districts boards (some 40 in number) have charge of the branch sewers under the general control of the Metropolitan Board. Their primary duty is to deal with small sewers, and see that the small drains or sewers from houses on the river bank are diverted from the Thames into the intercepting sewers in their districts. There are still some houses the sewers from which drain into the Thames, 36–40, 176, 12,816. The outfall sewers all discharge into reservoirs, one at Barking, and one at Crossness, the time of discharge commencing at high water and continuing for four hours afterwards. Barking was selected for the northern outfall because the sewage of a great portion of the Metropolis could reach there by gravitation, and so reduce the pumping. Crossness was selected on the south because for a distance of six miles, from Woolwich to Erith, there are no houses on the banks, and only a number of factories and works of an offensive nature. There was no other spot until Gravesend is reached, where so eligible a position could be obtained for the discharge of the sewage. To discharge it 15 miles further down, at Tilbury, would require a fall of two feet in a mile, which means lifting the sewage by pumps 30 feet, and the cost of doing this would be from 2,500,000*l.* to 3,000,000*l.*, and the pumping would represent another 1,000,000*l.* The cost of the works which have already been carried out (the system now in operation) has amounted to 4,000,000*l.*, which is exclusive of all the district sewers, and the proposed work on the storm discharges is also extra, 40–53, 55, 194–8, 12,950–4, 12,957*a*. He hands in a map, which shows a private scheme, proposed some time ago, for irrigating land with the sewage, 54. The Barking reservoir covers 9½ acres, and that at Crossness 6½ acres. Barking is 11½ miles, and Crossness 13½ miles, from London Bridge. Trinity high-water mark is 12 feet 5 inches above Ordnance datum, low-water is 7 feet 6 inches below datum, making a difference of 20 feet. Half tide is + 1·56 over datum. The bottom of the reservoir is + 2·75 over half-tide. The overflow weirs are 16·25 feet, or 3·75 above Trinity high-water; the available depth, therefore, is 13½ feet. The Crossness overflowing weirs are 2·5 feet higher than at Barking, and the available depth is 16 feet. The reservoir begins to overflow when the sewer is running half full. Barking reservoir will contain 35,000,000 gallons or 5,600,000 cubic feet. Crossness reservoir contains 25,000,000 gallons or 4,000,000 cubic feet, making a total of 9,600,000 cubic feet. In 1878, the quantity discharged at Barking altogether, including the average quantity of rain for that year, was, in 24 hours 13,120,000 cubic feet, which, in the eight hours that the reservoir has to store it, amounts to 4,373,000 cubic feet.

SIR JOSEPH W. BAZALGETTE—*continued.*

DESCRIPTION OF THE MAIN DRAINAGE WORKS, AND CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

During the discharge, the sewage flowing in is not stored, but flows through the reservoir, 55–63, 145-52, 12,668–84. The corresponding figures for Crossness are, total quantity discharged in 24 hours, 12,164,000 cubic feet, eight hours storage, 4,055,000 cubic feet, the two amounting to 8,428,000 cubic feet from the two reservoirs in eight hours, which leaves a margin over the actual capacity of the reservoirs, 64–8. The reservoirs are emptied each tide, 69–71. In times of excessive rain, when more flows into the reservoirs than they are capable of holding, there must be an overflow, just as there is at all the storm outlets into the river, and it must be far less objectionable at Barking and Crossness than in the Thames at London, 71–3. In the four years preceding 1878, the average annual increase in the quantity of sewage discharged was 14 per cent; he has not got the actual quantity since 1378, but has assumed that the annual increase since 1878 has been as great as it was prior to that year, 64, 100–10. The quantity of sewage discharged at Barking now (on these figures) would be in 24 hours 14,956,000 cubic feet, or in eight hours 4,985,000 cubic feet; and at Crossness the quantity would be 13,867,000 cubic feet in 24 hours, or 4,622,000 cubic feet in eight hours, making a total of 9,607,000 cubic feet, which on the average balances what the reservoirs are capable of holding. But as the flow of the sewage is not evenly distributed over the eight hours, the reservoirs may be overcharged, and are overcharged at times, even in dry weather. The Board of Works having foreseen this difficulty, had determined to enlarge the reservoirs, at a cost of 160,000*l.*, to the extent of fifty per cent., but objections having been raised to the position of the outfalls, and the Royal Commission having been appointed, the execution of this work has been deferred for three months, 75–6, 158, 170–5, 12,950–2. Some portion of the sewage of Acton, which is without the district mentioned in the Act of Parliament, drains into the Metropolitan system, and there are legal proceedings pending at the present time with reference to it. All applications from Acton and the surrounding districts to drain into the Metropolitan system have been invariably declined on the ground that the system is laid out to receive the drainage of a given area, and that area cannot be extended, 94–7, 202–4. Upon the margin of the area some districts have the right of sending their surface water into the Metropolis, and many make use of that privilege to turn in the sewage of their waterclosets. Great vigilance is used to prevent it. South Hornsey is one of the districts, 98–9, 177. The present quantity of sewage discharged at Barking and Crossness can be obtained, but it has not yet been worked out since 1878. The main intercepting system was not really completed until 1874, 100–10. At the time of a thunderstorm the quantity discharged from the storm outlets would have to be added to the total quantity discharged at Barking and Crossness to ascertain the total quantity which gets into the Thames; but as the main object is to get it into the river as quickly as possible to prevent the diluted sewage from flooding houses, the pumping stations pump the storm water direct into the river, and the quantity pumped could be ascertained; but it would only represent a very small quantity of the total water passing, 132–40. The mean high-water mark, which is the mean between springs and neaps, would be about 10·7 feet above Ordnance datum, 141–4. The discharge from the reservoirs begins at high water and continues for four hours after high water. In three hours the reservoirs are emptied and the sewage flows through the reservoirs into the river as it comes from the sewers for the remaining hour. The penstocks are then closed. A record is kept of the time of opening and closing at Barking, 145–52. Even when it is known that a large quantity of storm water is coming down, the penstocks are closed at the appointed time, and the reservoirs, when full, overflow into the river. It is impossible to allow the men to use their own discretion when they may leave the penstocks open or not. In times of storms the Thames and its tributaries are always much swollen, and it is a period when discharging sewage into it is really no nuisance. It is better, therefore, to allow the reservoirs to overflow than to continue discharging on the remaining two hours ebb, 154–8. He can ascertain, if required, the exact number of small sewers draining into the Thames, and the number

SIR JOSEPH W. BAZALGETTE—*continued.*

DESCRIPTION OF THE MAIN DRAINAGE WORKS, AND CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

of inhabitants, five years ago. To furnish the information up to the present time would necessitate a fresh survey of the river, 205–6. When a thunderstorm is local the Thames would not be in a heavy flood, but, as a rule, the Thames is in a state of flood in wet weather, 215. A statement of the quantity of sewage discharged at Barking and Crossness since 1878 up to the present time was handed in by Mr. Bidder in accordance with the promise made by witness (*see* Qq. 100–10). The total quantity for the four years is as follows:—

| Year. | Barking. | Crossness. |
|---|---|---|
| | Gallons. | Gallons. |
| 1879 - - | 33,616,848,827 | 31,065,965,556 |
| 1880 - - | 32,390,858,252 | 29,533,247,494 |
| 1881 - - | 32,632,794,334 | 27,223,090,538 |
| 1882* - - | 27,553,687,490 | 21,043,864,091 |
| Total - | 126,194,188,903 | 108,866,167,679 |

* Barking to 24th November. Crossness to 22nd November.

The fluctuation in the table is due to the rainfall to a certain extent, because a good deal of rain got into the sewers, and this is the reason why there is no continuous growth. (*See* Evidence, 12th Day, after Q. 6864.) He has had a table prepared which gives up to the present time the exact areas from which sewage is intercepted in square miles, the length of the main intercepting sewers, including branches, their dimensions, and inclinations on the north and south side of the Thames. The area drained on the north side is 48½ square miles within the metropolitan area, and 3·46 square miles outside the metropolis, making in all 51·96 square miles, say 52 square miles. On the south side the area drained within the metropolis is 51·21 square miles, and outside the metropolis ·57 square miles, making in all 51·78 square miles, now draining into the system. Of the remainder, viz., 16·57 square miles undrained, it consists mainly of agricultural land or nursery gardens, houses with large grounds attached, parks and commons, all of which have a very small population upon them. The sewage, if any, is either disposed of on the land itself or drains into the streams adjacent thereto. The sewage, he may say, is almost invariably disposed of on the land itself. This land is not likely to be built over, nor is it likely that it will ever come into the metropolitan drainage system. He hands in the tables, 12,494–502, 12,778–85, 12,804–15.

He will now proceed to reply to Mr. Baldwin Latham's criticisms on the capacity of the drainage system. The inference drawn from his (witness's) evidence in 1853 can hardly be accepted now, as at that time he had not prepared any scheme himself, and it was proposed by Mr. Morewood to intercept the sewage of 43 square miles by one sewer only of 10 feet in diameter, capable of discharging 19,000 cubic feet a minute; whereas his three northern outfall sewers when united in one are capable of discharging 33,000 cubic feet a minute. He deals with a larger area, but when reduced to the same area it will be seen that he has provided 50 per cent. more discharging power than the scheme propounded in 1853 provided for. He stated at that time that there would be an overflow upon 80 to 100 days in the year if that scheme was carried out, and Mr. Latham says if that was so the same state of things must exist now. This deduction is not correct, because he has given a larger discharging power in proportion to the area to be drained, 12,503–7, 12,746–65, 12,786–803. The western district was provided for when he carried out his system, because the sewers were made larger by 6 inches in diameter than was originally intended in order to take in the sewage from that district if need be. The amount of sewage to be intercepted on the north side amounted to 27,440 cubic feet a minute, and the western district gave 5,130 cubic feet a minute, making in all 32,570 cubic feet a minute; now Mr. Latham allows that the three sewers are capable of discharging 33,000 cubic feet a minute (each will discharge 11,000 cubic feet); therefore the outfall sewer is a proper size for taking off the whole of the sewage of the western district. Mr. Latham is therefore wrong in saying provision was not made for that district, 12,508–18, 12,746–65, 12,839–64. Mr. Latham's conclusion that although there were 29 inches of rain in 1875 none flowed off at Barking is based on two assumptions; one was, that the water supply was the same upon the north as upon the south, viz., 31¼ gallons her head instead of 30·4 on the north side, and also that during the years 1875 and 1876 he omitted to point out that the sewage of the western district had not then been diverted to Barking. He assumes that a considerable part of the sewage escaped into the river higher up than Barking. Taking the population in 1881 the daily discharge of sewage at Barking would be 77,739,032 gallons, which, deducted from the quantity discharged, namely, 89,404,916 gallons, leaves a surplus of 11,665,884 gallons, or 1,866,525 cubic feet for a rainflow for 51 square miles, which is equal to $\frac{1}{63}$ inch in depth for every day in the year. That represents 5·8 inches, or nearly 6 inches of rainfall running off at Barking, which is equal to nearly 12 inches falling. Mr. Latham's data are not correct, 12,519–23, 12,889–97. Mr. Latham, in alleging that in July 1876 there were 20 gallons per head leakage, has under-estimated the water supply per head on the south side of the river; he has not included the whole area by 24 miles, and has assumed that the 69,000 people residing on those 24 miles do not drain into the system. Now the actual discharge was at the rate of 46·88 gallons per head, and if the sewage proper, viz., 32·50 gallons per head be deducted, it leaves a difference of 14·38 gallons instead of 20 gallons. This is accounted for in the following manner:—One-fourth comes from manufactories and tanneries; one-fourth comes from the board's flushing; one-fourth comes from the flushing of the district boards, and the remaining fourth comes from leakage. He explains at length, by reading his Report on the inlets at Bermondsey, how the tanneries there take in water from the Thames and discharge it into the sewers, which causes much trouble to the Board as well as considerable expense in pumping, 12,524–33, 12,707–14, 12,804–26. The object in fixing the lowest part of the reservoir 2·75 feet above ordnance datum was to prevent the whole of the sewage being discharged at one time and to extend it over a period of two hours and a half, because it was thought better to let the sewage go down the river, and partially return when it would be more purified and diluted by the admixture of Thames water. The overflow weir is 5 feet 6 inches above the level of high water, so when the sluices are first opened there is at first a very rapid discharge from the reservoir, then having come down nearer to the tide, it empties more slowly, and is completely emptied in 2 hours 40 minutes. The gates are kept open longer to allow the sewage coming in to flow out, because the reservoirs are too small to take the entire quantity coming in, 12,567–77, 12,668–84. The reservoirs were not constructed with a view of carrying out any chemical process or deodorization in them, and he adds, there was no object in making the reservoirs large enough for the future population, because they can be added to now, or in 10 years time. The money would have been thrown away. As he has said before, the Board only awaits the result of this inquiry to carry out their work of enlarging the reservoirs, 12,578–9. In providing for double the maximum flow through the sewers he provided also for a quarter of an inch of rain, except in some of the outlying districts, when he allowed for one eighth of an inch only. He will supply the names of those places, 12,685–701, 12,839. The flow of the sewage not being uniform, owing to the distance some of it has to travel, the maximum flow is only 40 per cent. above the average. This he ascertained by an experiment made on the 12th July 1876, and to which Mr. Latham referred frequently, 12,702–12. In his Report of 1856, he gives the area on the north of Thames as 51·44 square miles, whereas it really is 50·21 square miles. He is, however, unable to say where the difference arises. The area of Acton, which contains 4½ square miles, is not included in the 50·21 square miles, 12,778–85. From Abbey Mills to Barking the three sewers are 9 feet each in diameter, and they each can discharge 11,000 cubic feet a minute. The 10 feet 3 inches sewer to Abbey Mills is capable of

SIR JOSEPH W. BAZALGETTE—*continued.*

DESCRIPTION OF THE MAIN DRAINAGE WORKS, AND CAPACITY OF THE DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

discharging 14,000 cubic feet a minute; but the 9 feet sewers above Abbey Mills have a discharging capacity of 3,690 cubic feet per minute in excess of the quantity they were intended to carry; and the flow of all three is limited below Abbey Mills, and they thus become of the right discharging capacity for the duties they were intended to perform, 12,786–93, 12,923–7. The weir in the sewers is placed about 12 inches from the crown of the sewer, so until the sewers are nearly full the storm outlets do not act. The sewers can, however, fill and run full even when the storm outlets are acting. A sewer discharges more when it is not running quite full than when it is running full as the frictional surface is less. The discharge when running nearly full would be 11,000 cubic feet, and when a foot from the crown the discharge capacity would be about the same. Mr. Latham has adopted a formula for discharging his sewer which gives rather a higher result, 12,794–803. In estimating the amount of sewage per head on the south side at 46·88 gallons, he took the population on the 51·78 square miles which drain into the metropolitan system as 1,113,000. None of that area drains direct into the river, 12,804–16. The water is taken in at the Bermondsey inlets for the tanneries from half tide to high water and down to half tide again, and the amount would be 4,000,000 gallons in 24 hours, that is to say, in the two periods of high tides, 12,818–26. From the table of the gaugings of the discharge of sewage at Crossness on the 12th July 1876, the weather being dry, there is, to his mind, nothing inconsistent with the opinion he formed that the flow is accounted for by the amount of water taken in by the tanneries, and from thence poured into the sewers, together with the water used for flushing, and that of the difference between his estimate and Mr. Latham's only one-fourth is due to leakage, 12,827–38. The western district sewage, it was originally intended, should be dealt with separately, and the Acton district never was intended to be included in the metropolitan area, nor does he contemplate taking it in now. The discharging capacity of 28,000 cubic feet was therefore thought sufficient; but, as he stated before, taking into account the addition of that district, and the future increase of the population, he provided a discharging capacity of 33,000 cubic feet per minute. The population at that time was 1,614,000, exclusive of the western district, and 1,766,000 including it; the contemplated population was 2,056,000 exclusive, and 2,353,000 inclusive of the western district. He will work out how much of the 28,000 cubic feet was margin for the increased population, 12,840–64. As further proof that the sewers are more than sufficient to carry off the sewage of the whole area, he had occasion from the 15th to the 19th May 1883 (only a few days ago) to divert the sewage from one of the three outfall sewers on the north side, and he very carefully watched the effect to see how high the sewage rose. In the middle level sewer when it contained the sewage of the high level in addition to its own supply it rose to a maximum height of 5 feet 2 inches, and in the low level sewer (there being some communication which equalized it a little, but not altogether) the maximum height was 3 feet 10 inches. His calculations showed that the three sewers during the time of maximum flow should be half filled with sewage, and the other half should be left for the quarter or eighth of an inch of rain. (He took the maximum flow to be double the ordinary or average flow). Now the quantity flowing through those two sewers at the time, instead of being half, was only one-third, so that in fact one of those sewers would carry off the whole of the sewage of London on the north side, assuming no rain, leaving two-thirds of his capacity, instead of one-half, and the sewers are, therefore, large enough to last to the end of the present century, 12,923–7.

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—Permission having been given to certain districts, not included in the Metropolitan area, to discharge their storm overflow into the natural outlets, such as the Wandle (for example), advantage has been taken by them to discharge their sewage into the streams and river. Where they have power, under the Metropolis Management Act, they take proceedings to stop it. But

SIR JOSEPH W. BAZALGETTE—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

there are other ways in which the Thames is polluted, over which they have no jurisdiction. The sewage of Stratford is discharged into the River Lea and flows into the Thames; at North Woolwich a few houses drain into the Thames, to connect which with the sewers would cost more than the houses are worth; Cold Harbour sluice, Beckton Gas Works outfall, and the shipping, all go into the Thames: and there is that which comes in above the outfall, 177–84. When designing the main drainage works, he thought, in selecting Barking for the discharge of the sewage, there would be a comparatively short period in which noxious sewage would remain in the river, and the question he had to deal with was that the Thames was a nuisance to the inhabitants of London. The lower reaches of the river at that time were not so important as they are now, and assuming that there is a nuisance growing up in the lower reaches of the river from the discharge of the sewage into the river at Barking and Crossness (though he does not admit the nuisance), the nuisance should be removed. 12,654–61. In the old times the nuisance in the Thames arose from the sewage in the water and upon the banks, and also from the deposit of the sewage at the bottom of the river, which gave off gases. It was, no doubt, aggravated by the length of time the deposit had remained there. He has never examined in hot weather the existence of smells in the water, as his sense of smell is not very acute, and he would not, therefore, detect it rapidly, 12,662–7. In the Report of Dr. Lethby, published as an Appendix to the Report of Messrs. Bidder, Hawksley, and Bazalgette, dated 6th of April 1858, the question of oxidation is referred to, and Dr. Lethby says that this may be obviated by defecting the sewage by means of lime and allowing the clear liquor only to be discharged into the Thames, or the sewage may be discharged in such a manner that it will mix with and be diluted by 200 or 300 times its bulk of river or sea water. The mischief which really results from the (then) present mode of disposing of the sewage is caused by the insoluble organic matters which collect upon the banks of the river near to the sewers, and there undergo perpetual putrefaction, 12,766–76, 12,907–12. From his own report of the 3rd April 1856 he reads extracts as to the various causes which combine to pollute the river. He concludes the report by saying that it is extremely undesirable, in a sanitary point of view, to cause sewage matter to become intermixed with sea water, and especially under circumstances which will occasion it to be brought up the river by the flood tide; but that if the sewage matter were poured into a much larger volume of fresh or freshened water in a running stream it would become immediately oxygenized, and cease to exist as a noisome and offensive agent. The experiments of Dr. Lethby and Dr. Odling fully confirmed his view, and the sites for the discharge of the sewage were, therefore, unhesitatingly selected at Barking and Crossness, 12,904-6. On page 116 of Dr. Lethby's Report, he says that the docks on the north side of the river which receive their water from the Thames below Blackwall are never offensive, while in the London and St. Katharine's Docks the water is always turbid, and in the summer time is offensive from the putrefaction of the mud. At the West India Docks the water is comparatively pure, and it is generally well stocked with fish. In the summer time the mud, however, undergoes putrefaction and kills the fish. At the East India Docks the water is still purer, and it is a rare circumstance for the mud to putrefy and the fish to be killed; while at the Victoria Docks the water is quite clear, fish are abundant, and the water and mud never show signs of decomposition or putrefaction. From this it would appear that the soluble or insoluble part of the London sewage is the cause of the mischief observed at the London and St. Katharine's Docks, and that it is quite innocuous by the time the water containing it reaches Blackwall. The organic matter does not decrease, but its condition is altered by the action of the air and by the agitation of the running stream. Those, therefore, who have looked upon the London sewage as an unchangeable log of wood floating up and down the river have taken a very erroneous view of the matter. So prone is the organic matter to undergo change and to complete its course of putrefaction, that it is doubtful if it exists as a putrefying body a few hours after its entrance into the river. During the time it has been traversing the sewers it has generally been so agitated

SIR JOSEPH W. BAZALGETTE—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

and broken up as to be in an advanced state of putrefaction. Almost all of the nitrogen has been changed into ammonia, and its sulphur into sulphuretted hydrogen, and then, when it reaches the Thames, it finishes the last stage of its putrefactive career by the rapid absorption of oxygen, and the formation of compounds that are comparatively inert, so that, partly by means of dilution and partly by the destructive powers of oxidation, the Thames possesses the means of self-purification which is fully equal to the contaminating injury to which it is at present exposed, 12,907. Taking the population for 1883 as given by Mr. Latham, and multiplying it by the water supply, it gives 9,690,000 cubic feet of sewage discharging into two ebb tides of 2,233,000,000 cubic feet of water at mean tides, which gives a dilution of 1 in 230, and that complies with Dr. Letbby's idea of dilution to effect purification, 12,908–15. He considers the river to be in a satisfactory state between Erith and Greenwich, and the statements which have been made have been very much exaggerated. Considering that there is no population, and that there are only chemical works in the neighbourhood of the outfall, no harm is occasioned by the discharge of the sewage there, and that there is nothing to complain of, 12,941–4. The sewage is very quickly diluted, and a mile or two from the outfall it disappears. It is no serious inconvenience either to the health, comfort, or enjoyment of the people who live on the river or on the banks. So far from people being poisoned by it who were in the "Princess Alice" accident, he has seen the water drunk at that spot, and there was nothing offensive in it, 12,945–6. Some of the members of the Commission have walked with him on the shore and found it quite clean. The statements he has heard in this inquiry have astonished him, as he has never discovered anything offensive until he got close to the outfalls. If the 4,000,000*l.*, which it is proposed to expend on the drainage works were handed over to him he could lay it out much more for the benefit of London by relieving London from floods or by making communication across the Thames below London Bridge, 12,947–54. If the sewage were discharged further down the river it would fall into a larger volume of water; but the water would be salter, and would be liable to create a nuisance, 12,955. An Act of Parliament was obtained, and the works were commenced, to carry the sewage to the Maplin Sands and utilise it there, but the scheme was not carried out, 12,953, 12,958–9.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—Every precaution is taken to prevent solid matter getting into the sewers by careful scavenging, and by gulleys to intercept the solid matter which may flow into the sewers from the roads, such as shingle and sand. In dry weather there is not much accumulation in the sewers now, and the first effect of a heavy storm is to wash away any deposit in the sewers, 208–14. By the time anything solid in its origin is washed out of the reservoirs it is tolerably well mixed up with the water. Bits of bone and iron sometimes come down the sewers, but not often, 218–222. In 1850, the system of catch-pits was introduced in London for the purpose of preventing the road detritus and other heavy matter from getting into the sewers, and it has been very successful in doing so. At first they were of very defective construction, and a great deal of detritus overflowed from the catch-pits into the sewers. Between 1850 and 1880 they have been very much improved and very largely extended. The average amount of detritus removed from the streets annually is about 775,000 cubic yards (one cubic yard is equal to a ton). Of that quantity 616,500 tons are removed by scavenging by carts, 133,000 tons are removed from the catch-pits, and 25,600 tons are removed from the sewers. Of these quantities 40 per cent. is road detritus, 40 per cent. is water, and 20 per cent. is garbage from the markets, and refuse. The cost of removing the deposit from the sewers is very great, so it is to the interest of the Board to intercept as much as possible; and if the catch-pits are properly looked after, and are emptied from time to time, they answer very well, 12,582–6, 12,590–5, 12,605–9. A sample of sewage taken at the outfalls before the catch-pit system was introduced would not be fair criterion of the amount of suspended matter delivered at the outfalls after the introduction of that system, 12,587–8. He is unable to give any evidence about the mud banks and smells; he confines himself simply to the drainage system, 12,589. Besides the quantity of detritus intercepted, some may have passed through the sewers as sewage, but he is unable to give an estimate of the quantity. In 1878 there were in all 1,710 miles of roads made up as follows.

Upon these roads were put 307,700 tons of macadam flint or hoggin, and off the granite paved roads 39 tons were probably worn away in the course of the year, 12,596–609.

DISCHARGE FROM THE MAIN OUTFALLS AT IMPROPER TIMES.—When the sewers bring down more sewage than the reservoirs are capable of holding, there must be an overflow into the river, just as there is an overflow at all the storm oulets. In the beginning of 1881 the reservoirs overflowed on forty-three days at Crossness at the time of flood tide, and at Barking the number of days was greater, 71–5, 164–8, 12,928–39. An instance when it was reported that the overflow from the main outfalls continued after the four hours was inquired into, when it was found that there was a slight leakage from one of the penstocks. This was at once stopped, 153, 12,939. He is not aware that a discharge was going on six hours after high water on the 30th June 1882. It would be contrary to practice, and the men have very strict orders on the subject. Any dereliction of duty of that description, if discovered, is severely reprimanded, 159–61. In flood times, and when there are heavy rains, the sewage has been discharged before the beginning of the ebb tide; at other times the discharge begins at high water and continues for four hours after. The discharge can be continued if desired until the return of the tide. He will furnish a table giving the hours of discharge for the past eight years at Barking and Crossness, 12,668–84, 12,928–39. He now hands in Tables A and B, which show the number of days on which overflow before high water occurred at Barking and Crossness for the eight years from 1875 to 1882, in consequence of the insufficient size of the reservoirs or from heavy rain. The discharge of sewage on the ebb tide at Barking varied from three hours in 1875 to four hours in 1882, and at Crossness from 1875 to 1879 inclusive the sewage was discharged for three hours, and, subsequently, for four hours after high water, 12,928–30, 12,935–9. In 1882 the small number of overflows is accounted for by the frequent discharge of sewage at the Deptford Creek storm outlet, as he explained before (*see Questions* 12,564–6. *Discharge from the storm overflow outlets*), 12,931–2.

DISCHARGE FROM THE STORM OVERFLOW OUTLETS.—At Deptford Creek the sewers which pass under it have an overflow for storm waters into the creek. When in times of storms the quantity the sewers are capable of holding is exceeded, it rises up in pipes, under pressure, opens some flaps into the creek, and the storm waters are thus discharged into the creek. This is in addition to the overflow from the main sewers into the intercepting sewers. A similar contrivance exists in the River Lea to relieve the northern outfall, 19–21. There are 35 outlets on the north side of the river for the discharge of storm water into it, and 12 on the south, but owing to their low position, at certain times of the tide they cannot discharge into the river, and the low lying districts in consequence are subject to floods. Serious complaints have been received from Pimlico and Battersea of the flooding of the basements by the overflow of the sewers which are dammed up by the tide at high water during heavy floods. To remedy this difficulty the Board of Works have determined to spend 1,500,000*l.* in constructing storm relief sewers which will carry off the storm water from the higher districts and force it by pressure into the river, thus relieving the low lying districts of the pressure of storm water from the high districts. One such sewer has been constructed in the Fleet Valley district, with very satisfactory results; another is being made at Vauxhall Bridge; and others will follow, 24–34. A record is kept of the times the overflows are opened at Deptford Creek and the River Lea, but not of the others. At Deptford the number of days of overflow between 1872 and 1879 was as follows:—

SIR JOSEPH W. BAZALGETTE—*continued.*

DISCHARGE FROM THE STORM OVERFLOW OUTLETS—*continued.*

| | | |
|---|---|---|
| 1872 | 21 days. | |
| 1873 | 15 ,, | |
| 1874 | 9 ,, | |
| 1875 | 20 ,, | |
| 1876 | 19 ,, | |
| 1877 | 30 ,, | a very wet season. |
| 1878 | 17 ,, | |
| 1879 | 21 ,, | |

That, of course, was only during a portion of the day. There is a lower flap which is not self-acting, and which is opened by hand in times of very excessive storms, when the upper flaps are not sufficient to carry off the storm waters, 113–20. He can obtain the same particulars for the period from 1879, 121. When the High Level Sewer, is flooded it escapes over the weirs into the rectangle sewers, and it then goes into the middle level sewers, and from there into the low level, whence it escapes into the Thames at low water through the storm overflows. The matter which overflows would be mingled sewage and water. At certain times of the tide the storm water is penned back, and that is the reason why the Board is constructing the storm relief sewers, 122–31. He hands in a table giving the number of times overflows have occurred, and of which a record has been kept, from some of the storm overflows. It is impossible to give the return from them all; in fact it is only at the pumping stations, or where some one has been placed in charge that the information can be given; viz., on the south side at Deptford Creek, Vauxhall pumping station (the Effra) and Battersea (Falcon Brook); and on the north side at the Western District pumping station, and at the River Lea, 12,555–6. The records from these five places are very incomplete, and the causes of the overflows cannot be given always. The average number of overflows for the ten years from 1872 to 1882 at the five stations is as follows:—

| | |
|---|---|
| Deptford Creek | 23·09 |
| Vauxhall Pumping Station | 20·66 |
| Battersea | 18·33 |
| River Lea (Old Ford) | 20·00 |
| Western Pumping Station (Pimlico) | 30·60 |

The average annual rainfall for the same period was 26·40 inches. The whole of the overflow is, of course, not sewage. It would vary with the different rains very much. With very heavy and continuous rain, the overflow would be very highly diluted, 12,557–63. The excessive discharge at Deptford in 1881 and 1882, as shown in the table, is the result of certain instructions given to the flapkeeper to discharge the sewage from the overflow outlet whenever the barometer was falling with an appearance of rain, because in 1879, he waited until the sewers were full, and the sewage when discharged burst out with such force as to blow away the wharf wall opposite to the outlet. (He produces a model of the high level sewer coming down to Deptford Creek, and explains the method by which it is worked.) The flapkeeper has discharged the sewage more frequently than was expected, but he has acted rightly, no doubt, in doing so, 12,564–6, 12,931–2. He hands in a complete list of all the storm outlets on the north and south side of the river, with the level, size, and exact position of each given thereon, of which all but two are self-acting, 12,726–9, 12,898–901.

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER.—Putting a float into the river at high water as compared with low water makes a difference of about twelve miles, that is to say if a float be put into the river 12 miles lower down than London Bridge below high water it will, upon an average of tides, float up to London Bridge. The sewage, therefore, having been put into the river at low water for some years and flowing up, caused a nuisance to the river, 5–8. The average contribution of the river to the sea (or the mean flow) is 84,500,000, cubic feet in each ebb tide. The discharge of tidal water past the outfall is 2,148,713,000 cubic feet, the two together making the water that flows down each ebb tide, 2,233,213,000 cubic feet. The tidal water is water which has flowed up and come down again. The proportion of fresh water to tidal water, roughly speaking, is about four per cent. The volume of sewage discharged at the two outfalls is 14,000,000 cubic feet, 75–85. The volume of water in the river at the outfalls as compared with the volume of sewage discharged into the river may be taken as 150 to 1, 87. Captain Burstal and he made a number of float experiments (assuming that the sewage was a solid block like a float) to ascertain what would

SIR JOSEPH W. BAZALGETTE—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

be its action if carried down by the river two hours after high water. On the 13th July 1851 a float was put into the centre of the river, two hours after high water, opposite Barking creek. At low water it had reached 11¾ miles below the creek, and returned on the next flood to one mile above This was a period of spring tides. As the neaps came on it continued to work lower down at each succeeding high water, and on the 24th July it was 13 miles below Barking Creek at high water. As the floods became stronger it worked up the river again, and on the 29th July it was five miles below Barking Creek at high water, having worked up nine miles from high water neap tides to high water spring tides; the excess of the ebbs over the floods being five miles in 14 days. On the 6th August 1851 a float was put in at exactly the same spot, the tides being then lowest neaps, and on the 12th August it had worked up to 6¼ miles above Barking Creek at high water. On the 21st August it was 9½ miles below Barking Creek. The excess of ebbs over floods in this case was about seven miles in 14 days. Roughly speaking, it may be assumed that a substance in suspension works up the river about one mile per day at each high water as the springs strengthen, and down the river two miles a day as the tides fall off. The sewage however is not like that solid substance. If it were so, the effect would be that sewage discharged at London at low water daily would in a fortnight produce such a concentration of sewage that the stream would be one of sewage instead of one of water at low tide, 86–91, 12,902–3. The float was kept in mid-stream during the time it was in the river, and it will presently be shown what the actual course of the sewage in the river is, and that a very short distance below the outfalls it ceases to be objectionable, 185–7. Experiments have been made of the velocity of the river at different depths, and with different materials to ascertain the difference in the surface mean velocity. The floats were weighted, so that they were affected by whole depth of the tidal flow, 216–7. In 1866, when Captain Burstal was directed by Government to make the float experiments and to test the original experiments, he received instructions from the Metropolitan Commissioners of Sewers to make them in concert with Captain Burstal. They supervised the movements of the floats, and checked the results, but did not follow them up and down, 12,581–2. The oscillation of the sewage is spread over a distance of about 12 miles from high water to low water, as judged by the movement of the floats. With a spring tide it would rise higher up the river, and with a neap tide it would go further down, 12,610–25. Prior to the construction of the works, he formed an opinion that the sewage would be rapidly destroyed by dilution and oxidation after its discharge into the Thames, and that it would never reach the sea in the form of sewage. This was the result of general observations and not of any special experiments, and is embodied in several reports which he will produce at a future date, 12,626–38, 12,652–3, 12,902–7. The question as to how far oxidation would assist to deodorize the sewage, both as regards volume and time, was taken into account when designing the main drainage works, and the solid constitutent parts of the sewage going into the Thames were also fully considered, 12,639–51, 12,916–22. He now proceeds to read at some length extracts from his Report, dated 3rd April 1856 on the distribution of sewage from oscillation, pages 8, 9, and 10, and he describes the course of the float experiments in 1851, the result of which he has stated previously. (*See questions* 86–91). 12,902–7. Sewage discharged at high water at any point is equivalent to its discharge at low water at a point 12 miles lower down; therefore the construction of 12 miles of sewers is saved by discharging the sewage at high water instead of at low water, 12,903. He reads a further extract from his Report showing that he calculated the solid matter at 250 tons a day for the prospective population of 3,500,000, taking both sides of the river, the existing population at that time being 2,500,000. Dr. Tidy's estimate of 294 tons for a population of 4,000,000, viz.: the dry matter in the fæces at 97 tons, and the urine at 197 tons a day, is a little in excess of his estimate, if the dry matter in the urine is taken as forming a solid deposit. Messrs. Bazalgette Law, and Chatterton, in their Report of 15th April 1878, assuming 23 grains of solid matter to the gallon, estimated the total solid matter discharged into the Thames from

SIR JOSEPH W. BAZALGETTE—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

120,000,000 gallons of sewage at 176 tons per day. Dr. Tidy gives from 23 to 25 grains per gallon as the quantity of solid matter in normal sewage, showing that our estimate of 250 tons was in excess, 12,917–22.

POPULATION TO BE PROVIDED FOR.—Mr. Latham's estimate of the existing population, he is disposed to agree with, and that there is an increase of 500,000 people up to the present time. But in the capacity of the intercepting sewers, provision has been made for double the average flow, which is the same thing as the ordinary flow for double the population, and that double flow was over estimated. Instead of being double it is only 40 per cent. more in consequence of the want of uniformity of the flow, and this he overlooked in making his design. Now the result of that is this, assuming that the population at the present time to be, as stated by Mr. Latham, 3,975,468, and assuming the maximum flow to be 40 per cent. upon that, it would be equivalent to a population of 5,565,656 with a uniform flow; but the population actually provided for with a uniform flow is double what was provided for at the time of Messrs Bidder, Hawksley, and Bazalgette's report, being 6,897,000, so that there is a balance of 1,331,344, supposing the flow to be equal; but making allowance for the additional 40 per cent. that gives room for an additional population of 950,960 (nearly 1,000,000); that is to say, with the 40 per cent. flow upon a total population of 4,926,400, or nearly 5,000,000. That population, according to Mr. Latham's table, would be arrived at in the year 1896. He does not quite agree with Mr. Latham's table as to the increase of population, for London is getting filled up, and will not increase. It has been shown that it is not increasing so fast as it did formerly, 12,534–6, 12,685–711. In his Report, dated the 3rd April 1846, he says the amount of sewage proposed to be intercepted from the more closely inhabited districts has been estimated upon data which makes provision for the increase of future generations. Thus where the population as at present existing exceeds 30,000 to the square mile the actual numbers are estimated for, and where it is less, allowance has been made for that number in order to provide for future increase. The supply of water per head has been reckoned at five cubic feet per diem, being on a more liberal scale than now actually obtains, and of this quantity it is contemplated that one half will pass away during six hours of the day, 12,905. In those parts of the suburbs which are not likely to be built upon he provided for a possible increase of population varying from 10,000 to 20,000 to the square mile, instead of 30,000, 12,903.

RAINFALL TO BE PROVIDED FOR.—With regard to Mr. Symons' evidence on rainfall, he believes his calculations to be wrong; in the first place he based those calculations upon years subsequent to 1856 when the rainfall. Mr. Symons admitted, was excessive. Then he (witness) stated, in reply to Q. 9, that the number of days upon which (prior to 1856) a quarter of an inch of rain fell was 25, but he referred to rain running off, and he showed that provision was made for a quantity equal to a quarter of an inch running off. The total quantity of rain running off in the Savoy Street sewer was shown in Messrs. Bidder, Hawksley, and Bazalgette's Report by gaugings to be 68·5 per cent. of the total rainfall in the 36 hours when rain fell, and in the case of the Ratcliffe Highway sewer was 48 per cent. of the total rainfall, so that is conclusive evidence that the rainfall of 0·4 is not likely to yield more than a quarter of an inch. So when 0·4 of an inch of rain falls you expect to get a quarter of an inch running off through the sewers, and in excess of that to get an overflow. Now there were only 12 days upon which more than that quantity fell, 12,537–9, 12,734–45, 12,865–884. Then Mr. Symons divides the quarter of an inch falling in 24 hours into hundredths of an inch per hour, and assumes $\frac{4}{100}$ths of an inch running off in one hour to represent the same thing as a quarter of an inch running off in 24 hours. This is most erroneous, for that amount falling on a dry surface, and in many cases upon a very small surface would really produce no discharge into the sewers at all, and to say that it would produce an overflow, is absurd. If that argument is correct you might make it infinitesimal, and say that $\frac{1}{6000}$th part of an inch falling in one minute would fill the sewers, whereas it would not affect them, 12,539–45, 12,715–25.

He has taken 104 days in 1877 upon which Mr. Symons has said that 0·4 of an inch fell, or over, and the assumption as it stood was that upon those 104 days the sewers must have been full and some overflow taken place. He has analysed this, and finds that—

| | | | | |
|---|---|---|---|---|
| On 40 days that quantity fell for one hour only in the | | | | day. |
| ,, 24 | ,, | ,, | two hours | ,, |
| ,, 16 | ,, | ,, | three ,, | ,, |
| ,, 15 | ,, | ,, | four ,, | ,, |
| ,, 3 | ,, | ,, | five ,, | ,, |
| ,, 5 | ,, | ,, | six ,, | ,, |
| ,, 1 | ,, | ,, | eight ,, | ,, |

If he adds up all those hours together it reduces the 104 days to 10·37 days of 24 hours each in which the rain was actually falling.

On the same principle the results for 1878, 1879, and 1880 are given below.

In 1878 there were 8 days of 24 hours each in which that quantity was falling; in 1879 there were 10·4 days, and in 1880 there were 8·4 days. The periods for which the rain fell for a long time decrease in each year. It follows therefore that very few, if any, of the rainfalls mentioned by Mr. Symons were of sufficiently long duration to contribute to the sewers a quantity equal to a quarter of an inch running off in them from the whole metropolitan area at the same time, 12,546–9. In many cases where rain has fallen two or three hours in a day there have been dry periods between the showers, and the rain has dried and evaporated. Then these rainfalls are recorded at Kew, and it does not follow that the rain fell uniformly over the whole of the Metropolis at the same time. It is more than probable, on the contrary, that none fell upon the whole area upon any single occasion. He has prepared a comparative statement of the rainfall at Kew and at Greenwich for the same period, which he hands in, and it is curious to note that they do not agree in any single instance. It shows that there is the greatest inconsistency in the fall as might be expected. An ordinary rainfall does not cover the whole 117 miles, the rain cloud passes over from one part of the metropolis to the other, discharging first at one hour in one part, and at another hour in another part. He has in the table at the end worked out very carefully the number of days, and the number of hours per day in which 0·4 of an inch fell, and in which one-tenth of an inch of rain fell in one hour. In 1877 the rainfall lasted at the rate of one-tenth of an inch per hour for two days upon the average, equal to 48 hours in the year; in 1878 for 2·8 days of 24 hours; in 1879 for 2·5 days of 24 hours; and in 1880 for 2·5 days of 24 hours, 12,550–2, 12,885–8. Rainfall of $\frac{1}{100}$th of an inch, or of $\frac{4}{100}$ths of an inch in an hour in dry weather would scarcely do more than wet the surface. It would not charge the streets with so much water as a water-cart, as that throws the water more heavily on the surface, but the cart does not cover so large an area, 12,553–4. Two inches of rain in an hour have been known to flood the sewers, and at Paddington, in one instance, building operations had to be stopped on account of the rising of the sewers during very heavy rain, 12,715–25, 12,940. A very much larger proportion of rain finds its way into the sewers in the most populous parts of London than is the case in those areas which are less urban in character. The effect is not felt in the sewers the moment rain begins to fall, because it takes a certain time to get in, but the rain will continue to run through the sewers after the fall has cased, 12,738–45. The 28,000 cubic feet per minute discharging capacity allowed for an eighth of an inch of rainfall upon 11 square miles, and a quarter of an inch of rainfall upon 27 square miles in 24 hours. He did not assume that it would fall in any given time, but at some period during the 24 hours. If it fell in half an hour he would qualify that by saying not over the whole area, as it would then be a thunder shower only. The rainfall provided for was an eighth, or a quarter of an inch, running off in the sewers divided over a period of 24 hours, 12,865–74. Rain sometimes falls as slowly as $\frac{1}{200}$th of an inch in an hour, 12,875–84. In his Report of the 3rd April 1856, he stated that it was proposed to intercept in the urban districts a quantity equal to a quarter of an inch running off, which is equal to about $\frac{1}{100}$th of an inch per hour; any amount in excess of that being discharged into the river by the drainage sewers. In the more thinly populated districts provision was made for only one-eighth of an inch running off, 12,903.

SIR JOSEPH W. BAZALGETTE—*continued.*

RAINFALL TO BE PROVIDED FOR—*continued.*

## Mr. GEORGE CHATTERTON.

Civil Engineer and Associate Member of the Institution of Civil Engineers.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has been professionally engaged very frequently on the Thames since May 1877, in taking soundings and sections, more particularly in the neighbourhood of the main outfalls for the West Kent Main Sewerage Board, by whom he was employed as Assistant Resident Engineer. His work was quite independent of the metropolitan system. Their outfall is near Little Powder Creek in Long Reach, 12,960–8, 13,129–32. He was taking soundings only during the last three hours of the ebb tide in Long Reach, and in that way he had a very good opportunity of judging of the condition of the river when the metropolitan sewage would be passing down. It reaches that part of the river in three hours. There was no perceptible smell of any kind, but there was an indication of the sewage. By watching the river very closely upon a very calm day, he noticed corks and bits of vegetables, and traces of grease which would float upon the surface, but there was no possible means of detecting any large bulk of sewage by the nose or the eye, 12,969–70, 13,063–4. He does not agree with Mr. Latham that the river would become noxious at a temperature of 65°. It must be near 70° than 65°, because according to the tables Mr. Latham handed in, the temperature of 65° was reached upon 19 days in June 1877, 25 days in July, and 30 days in August; and during those three months even when the temperature was above 65°, he never heard of a complaint nor noticed anything offensive in the water. The same absence of smell and perception of sewage applies equally to the autumn months, 12,979–82, 13,063–4, 13,152–7. In 1878 he was engaged upon the river on 37 days, and except at the outfalls he never smelt the river of sewage. His sense of smell is as good as most people, 12,987–9, 13,169–86, 13,200–17, 13,229–37. On the 23rd of November 1878, he went down the river with the members of the Metropolitan Board of Works to ascertain the condition of the river, in consequence of the complaints made at the time of the "Princess Alice" disaster. There was a very disgusting discharge of tar refuse from the outfall at Beckton, of which he obtained a sample, and it was analysed by Mr. Keates. It was disgusting, and had a strong tar smell, and from its appearance he thinks it was likely to be a deadly poison. On the day of the disaster, a very severe fire occurred at Messrs. Price & Co.'s works, which might have accounted for the offensive smell on the water at the time of the accident, 12,990–2, 13,187–92, 13,194, 13,197–9. In 1879 he was frequently upon the river taking soundings, and he also took the temperature of the water in Long Reach. In May it was 62°, and the condition of the river was very good. On the 18th July, the temperature was 67·8°, and he has never noticed any smell from the sewage in that part of the river when working there, 12,933–4. In 1882 he was 59 days upon the river, and on the 22nd May he went to Barking and traced the discharge down the river. When the sewage first comes from the outfall, the smell is most dreadful and most sickening, and never can be forgotten. At a quarter past five he put a float into the middle of the sewage immediately off the outfall. In half an hour the float was abreast of the lower portion of the reservoir moving slowly. He collected samples of the water or sewage in test-tubes, and it smelt strongly. At 6 p.m. the float was opposite Lawes Chemical Works, and particles of grease and bits of vegetables showed that something had been discharged into the river. There were traces of sewage three-quarters of a mile below, but mostly in the shape of floating particles. At this point there was no smell of sewage in the air unless the water was shaken up in a test-tube, 12,996–13,008, 13,200–17, 13,229–56, 13,371–98. At a mile from Barking the water when shaken smelt faintly, as it did also a quarter of a mile further down. The float was then to the south of mid-channel. There was no smell in the air then. Off Half-way House, the float was 100 yards from the south shore, and there were the same traces of sewage, but the solid particles of sewage had disappeared before Crossness was reached, and the water when shaken had no smell, 13,009–13. The float was 200 yards from the Crossness Quay Wall, a little below the outfall, and off the Belvedere Guano Works the water smelt when shaken, but there was no smell in the air until Johnson's Fish Manure Works were reached, when the smell from the works was worse than usual. At Rainham Creek, traces of sewage were

## Mr. GEORGE CHATTERTON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

visible setting over the north shore, but there was no smell, 13,014–22, 13,273–4. Off Coldharbour Point, the float was 200 yards from the north shore, and there were vegetable particles visible. He finally lost sight of the sewage opposite the Royal Hotel, Purfleet, seven miles from Barking, 13,023–32. The evening was most favourable for tracing the sewage, being calm and bright, 12,996, 13,029, 13,036, 13,265–6. There had been little or no rain for the sixteen days prior to the 22nd May at Greenwich, 13,037–8. In 1882 he took a number of samples of the water, which have been analysed by chemists. *He hands in* a plan showing the position of those samples, and a cross-section of the river showing the exact spot and state of the tide at which each sample was taken. (*See* Appendices A., K., 1 and 2), 13,039–42. During the whole of 1882 for a reasonable distance below Barking and Crossness, there was no smell from the water, even when its temperature was 65° or 66°. He tried every possible means to detect it by smelling the water with his face only one inch from it, and going astern of a screw steamer. Even the fisherman, who are the first to complain, admitted there was no smell last year, 13,043–8, 13,200–17, 13,229–33. He has seen offensive matter matter discharged from the Beckton outfall recently, and on the 3rd of July he noticed a large quantity of sewage discharging from Bow Creek at low-water. That was West Ham sewage brought down by the River Lea. He has seen refuse coming from the factories, but never in any large quantity. A good deal of refuse is pumped into the river from barges also, gas-works refuse from the works above Vauxhall Bridge, and leakage from paraffin ships, 13,049–55, 13,275–85. On the 27th July he could not distinguish the Barking sewage 1,000 yards off. The smells from the factories on some days in that month were very bad, 13,056–8. A good deal of sewage is discharged into the Thames above London Bridge, and on the 15th August he saw some very strong unpurified sewage discharged into river at Chiswick. A sample was taken by the chemists, 13,060–2. He hands in a table showing the gaugings taken at Seething Wells by Mr. John Taylor, Engineer to the Lambeth Water Company, for the month of May 1882. The height of the Thames at this place above summer level is also given. There was not much water coming down at the time he was engaged on the river. The following figures show the quantity on the days he was examining the river:—

| | | | |
|---|---|---|---|
| On the 20th May 1882 | - | 577,000,000 | gallons. |
| ,, 21st ,, | - | 601,000,000 | ,, |
| ,, 22nd ,, | - | 653,000,000 | ,, |

The greatest quantity in the month was 1,697,000,000 gallons in 24 hours.

The mean daily flow is 833,000,000 gallons.

(*See* Appendix A.L.), 13,071–7. He has examined the sewer outfalls, and for any person working in the immediate neighbourhood of any one of them there would be a local nuisance. He hands in a plan of Erith, on which the outfalls are marked. (*See* Appendix A.M.), 13,097–8, 13,106. The mud at Messrs. Beadle's wharf, close to which a 15-inch sewer discharges into the river, remains uncovered by the tide for three hours. He has seen sewage discharging from that sewer of the worst kind, because it is old stagnant sewage, which is far more objectionable than fresh sewage, 13,098–105, 13,110. The most important sewer (marked C. on the plan), discharges at the flour-mill close to the causeway, and runs over the mud left there in a most disgusting state. He found a quantity of sewage there which had been deposited by the previous tide. The mud all along that part is fouled by the Erith outfalls, of which there are a good many, 13,110–3. There are 31 factories on the river which carry on noxious trades. They emit very bad smells, and the worst are those on the north side of the river between Erith and Woolwich. He has not noticed any noxious discharge from these factories, except from small pipes in a few instances, and at Beckton, 13,118–28. All his details as to temperature of the river are taken from his level books, in which he has copied the records from those at Greenwich, and if necessary, he will produce that information from 1844 to 1879, 13,152, 13,340–3, 13,400–4. In 1878, out of the 37 days, he was on the river a good many of those days were prior to April, and on business unconnected with this Sewage Inquiry, 13,168–86. The state of the water in November 1878 would be no criterion of the state of the water at the

MR. GEORGE CHATTERTON—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

time of the "Princess Alice" disaster, but from its condition, the Board of Works were satisfied from the report of Mr. Keates, that there was nothing in it to poison those who were drowned in September, 13,187–92. The sewer at Beckton is egg-shaped, and about 2 feet 6 inches high. It is the worst place he has been in in his life, and the foreshore is the most disgusting condition. The smell coming from there is a gasey kind of smell, in fact a heterogeneous collection of smells, 13,193–4. His original notes for 1882 on the condition of the river he has not got, but they are contained in the proof he produces, 13,208–17. He has noticed a great deal of bubbling in the Thames off Jenningtree Point, in Erith Bight, and in Long Reach, on summer evenings, which he supposed were in some way the result of putrefaction, but on smelling them he could not perceive any odour coming from them. He has noticed them also when sounding, and, strange as it may seem, he has seen bubbles rising from a sandy bottom. He thinks the bubbles are harmless, and that no nuisance arises from them, nor does he believe that the patches, referred to by witnesses, which rise to the surface are a nuisance, 13,218–28. He does not think that when he followed the sewage on the 22nd of May, that the circumstances were favourable to his case, because he was kept for three-quarters of an hour in the middle of the sewage, before it began to run away, and so he worked in an abnormally large quantity of sewage. More is discharged in the first hour than afterwards. Had his float got out of the sewage earlier, and gone off with the tide, then the experiment would have been more in his favour, 13,233–58. The sewage is discharged through a culvert by raising the penstocks in the reservoir. The sewage rushes out at first very rapidly, and when it reaches a sufficient level, it falls gradually with the tide, taking four hours to discharge. The level of the weirs of the reservoir is 16·50 feet above ordnance datum, 13,259–64. The passage of a steamer through the sewage would not have the same effect as shaking a sample in a tube, because the smell has some space to disperse in, whereas in a tube the top is closed. Nevertheless to sit in a boat behind a steamer is a capital way to smell the river, 13,267–72. The condition of the river in November is better than it would be in October, on account of lower temperature, and also on account of the greater quantity of water coming down, as a rule, 13,330–2. In August and September 1882, he was taking soundings from half a mile above the Corinthian Yacht Club to half a mile below Messrs. Easton and Anderson's Works, and he took 44 cross-sections of the river between those two points. The sections were 400 yards apart, and his level books will give all information as to distances, dates, &c. These he will produce for the inspection of the Commission. (These were subsequently handed in for examination), 13,333–43. He can, speaking generally, distinguish between the smells from the various factories on the river, and with practice they can easily be distinguished. He has never smelt the sewage at the same time as he has smelt the factories, but he thinks he could detect the difference between the sewage smell (if he were just below the outfalls) and the factories smell, 13,362–72. The sewage of the 507 undrained houses in Erith, being concentrated as it is, will cause a nuisance when discharged upon the middle of the mud at Erith, and would account for the complaints made by those men who were excavating a channel for Mr. Beadle, 13,373–9. There was no smell from the Thames in Erith Bight in 1882 he is positive, and every one in Erith to whom he spoke on the subject agreed with him; nor was there anything offensive. He considers that Erith Bight is a very pleasant place to spend the summer in, 13,380–5.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—He had to take foreshore sections between high and low water, and he never found the mud differed from ordinary Thames mud or any other mud, nor was it more disgusting in smell. This was over six miles from Crossness. He has been down in that part of the river frequently each year since 1877, and he does not think it is possible, as far as the eye or the nose is concerned, to detect any change in the mud upon the foreshore. It has not changed in the slightest. Owing to the extensive dredging operations which have taken place in Long Reach during the last two years, the river on the

MR. GEORGE CHATTERTON—*continued.*

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

north side has been much deepened, and the set of the tide in consequence, is a great deal more on the north side now than it formerly was. There is no accumulation of mud taking place on the south side, 12,971–77, 13,133–41, 13,345–50. In 1878, he examined the banks and saltings all the way down from Greenwich to Yantlet, more particularly on the south side, with the view to see how much they had been washed away. To the best of his belief, there is no difference between the mud at Erith, and the mud at the mouth of all the creeks down the river. He could detect no difference. It is light coloured at the surface, and black below, 12,983–6, 13,065–70, 13,161–7. He obtained samples of Thames mud while taking soundings, but he saw none which had the filthy appearance described by some witnesses. In Erith Bight, the mud is slimy and sloppy, and he would not care to have to work in it. It is certainly lighter in colour than the mud in the river Mole, 13,065–70. The accumulation of mud at Erith Causeway is caused by the slack water, for wherever there is slack water in any part of the Thames for any lengthened period, there must be a deposit, because the suspended matter goes to the bottom. Now the river at Erith Causeway is, of all parts, the slackest. On an ebb tide, at three hours after high water, there is slack water there, and at three and a quarter hours after high water, there is a considerable eddy tide opposite the Corinthian Club causeway, of one and a half miles an hour. At the pier there is never any tide up, as the causeway lies between two currents, one going up, and the other going down, and at no time of the tide is there any considerable current over the causeway. There are some abnormal conditions at work there from the enlarged sectional area. If you integrate the whole cross section, and add the whole tide running in one direction, and subtract the eddy tide running in the other direction, the true mean velocity of the stream would be obtained, 13,085–96, 13,405–8. In order to bring barges up to the coal wharf below Erith Pier, a channel has been excavated in the mud, and to keep it clean, a tank has been constructed which fills at high tide and is discharged at low water, to flush the mud out of the channel; this, however, is not sufficient, and several men are kept constantly employed in trying to clear away the mud, 13,106–9, 13,386–8. The Club Causeway is constructed on piles, which allows the water to have free passage through them. There is, therefore, no local accumulation of mud there. The town causeway is a solid groyne running out, and the mud is heaped up on the ebb side. The construction of that causeway no doubt adds to the accumulation of mud at that place, 13,114–7, 133,51. Every time he took soundings, he took a sample of the mud and examined it to see if it had any smell, as he wished to become practically acquainted with the character of the river before the West Kent sewage was discharged into it. He was taking observations frequently in May 1877, and from June to the end of the year he was wholly employed on the river, 13,142–51, 13,158–60. His dates he gets from his level books, which only show where the mud is. He has no notes or memoranda of his soundings, but will produce his books if desired, 13,152–60. In 1878 he was engaged by the Metropolitan Board of Works to make observations in connexion with the Mud Inquiry, and a good many of the days he was on the river in that year were prior to April, 13,175–86. Prior to 1877 he had no knowledge of the state of the mud in Erith Bight, but in 1878 he drove a tube into the mud at Erith 10 ft. deep. There is a slight difference in the colour of the mud along the Bight, but there is no great difference in the mud near the causeway as compared with that in other parts of the Bight, 13,310–12. He has no experience of the mud there in 1877. In 1878 he was a dozen times between Purfleet and the outfall, but has no record of the number of times he was in Erith Bight. In 1879, 1880, and 1881, he was very seldom there, but in 1882 he was there very frequently from May to November. Out of the 59 days he was on the river in that year, he was working 45 days in the neighbourhood of Erith. Some of the sections he took were in that immediate locality, 13,313–29. There is a slight difference between the mud at the Corinthian Yacht Club causeway, and the town causeway, which can be detected by the eye. It is slightly darker and more compact at the Club causeway, and it is due he thinks to the stronger current there, which washes away the finer particles. There is

## Mr. GEORGE CHATTERTON—*continued.*

### Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

a difference in the texture of the mud, if he may so call it. He has been on Erith Pier at ebb tide and has seen the deposit of mud there. The accumulation of mud at the town causeway is due to its bad construction, and is generally acknowledged by the Eirth people to be so, 13,346–51. He is aware there is a deposit of mud on the lower side of the causeway, but from two feet to two and a half feet below its level. He would not be surprised if its depth was 6 to 8 feet, as he has found it to be 10 feet in one place, 13,352–4. In spite of that, he believes it to be ordinary river mud, and does not think it is slimy, nor is he aware that Mr. Beadle in his evidence stated it was so, 13,355–9. The mud smells where the Erith outfall is situated, but, taken as a whole, it smells no more than the river mud, which always smells a little. On this point, scientific witnesses will be able to give evidence of a more reliable nature than he can do, 13,360–1. No doubt there is a tendency to silt up at the place where the flushing takes place, but the excavation at Mr. Beadle's wharf is of recent date. He agrees with that part of Mr. Beadle's evidence which relates to this silting up, and that he has always found it necessary to keep one man to look after it, but the cause of it is, that foreshore low water line has gone out at Erith causeway an enormous distance within the last few years, and the increasing deposit of mud is exactly what must take place on account of the slack water. Below Erith Pier the foreshore has not gone out an inch since 1833, comparing it with the chart, but it will continue to go out above the Pier, to what distance he cannot say, 13,386–8. He is not aware that, in a report upon the drainage system in 1857, it was stated that Erith Reach would not be a fit place to receive the sewage because it would silt up, 13,389. He knows for a fact that the accumulation of mud near the Club causeway is not largely composed of sewage, and the statement of the man in charge of the club-house, that it is composed of "that which comes from the human frame," is absurd. The man is strong and healthy, and his children are always playing about in the mud. He does not know that any of those children have had any illness, but he knows the man well and has often landed at the Club causeway, 13,390–3. No one speaking truly could say there was sewage in Erith Bight, and speaking ordinarily, it will not smell of sewage, 13,394–5. The samples of mud which he took for the former inquiry were all analysed by chemists, 13,396–7. The tide flowing down does not come into Erith Bight, but as it flows up, he has no doubt it would come into the Bight, 13,406–10. Mr. Law will, when examined, produce comparative sections of the river for different years, showing how much the bed of the river has been dredged of late years, which the Metropolitan Board of Works contends has caused this advance in the low water line, and they deny that it is caused by the deposit of sewage, 13,411–13.

Injury to Fish.—In the summer time the fish are taken out of the wells of the fishing boats at Gravesend. They are conscious of the effect of the sewage, not of the sewage itself. In the winter time he has seen the Dutch eel boats passing through the water by the outfalls, 13,033–5. He has frequently seen people catching fish at Gravesend, and he has watched the fish being brought up in wells through Long Reach and past the outfalls on the 7th August 1882. They did not seem at all uncomfortable, and the captain of the boat told him it was the usual thing, 13,059–286. He does not remember that year being very wet, 13,287.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He never noticed any offensiveness during the hot weather in 1877, nor did he hear any complaint from the men who were working in Long Reach at that time, and there were between 200 and 300 men employed. They used to bathe in the river in hot weather. It was not possible for anyone on the banks to tell either by eye or by nose whether there was any sewage being discharged from the main outfalls or not, 12,978.

Set of the Tide.—Generally if a float be put into the river opposite Barking outfall at high water, it will move at first very slowly until opposite Barking Creek. It will then begin to be deflected towards mid-channel; 1,000 yards below the outfall it will be in mid-channel, and will then set over close to Leatherbottle Point. Having turned the point, it will move parallel to the Crossness Quay wall until nearly opposite the Belvidere Guano

## Mr. GEORGE CHATTERTON—*continued.*

### Set of the Tide—*continued.*

Works, when it will set over to the Essex shore, and pass close to Cold Harbour Point; it will then pass down the centre of Erith Rands to about opposite Messrs. Easton and Anderson's works. If a float be put into the water two hours after high water, it will take the same course to Leatherbottle Point, but then it will cross over to the deep water upon the north side, and pass close to Dagenham jetty, and so along the north side of Halfway Reach and Erith Reach following the course as described already, 13,078–81. The sewage discharged at Crossness follows a parallel course to the river wall, until it reaches Jenningtree point, when it is deflected to the Essex side, and goes down the northern side, passing close to Cold Harbour Point in deep water. Erith being in a bight, the sewage never passes straight into the bight, but keeps the opposite side when discharged either at Barking or Crossness. He has made many observations, but has never seen a float go into Erith Bight at that time of the tide, 13,082–4. When making float experiments for the purposes of this inquiry later in the year 1882, a float traversed Erith Bight. His notes and observations of these experiments he did not keep he regrets to say, 13288–309.

## Mr. THEODORE MAXWELL, M.D., F.R.C.S. Edin. B. Sc., San. Sc. Cert. Camb.

Fellow of the Chemical Society.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He has lived at Woolwich for five years, and his practice extends all over Woolwich and Plumstead. He holds a Cambridge University Sanitary Science Certificate, 13,414–9. His patients include all classes of people, 13,421–2. He has seen very little typhoid fever in the district, and he cannot conceive of its being particularly prevalent unknown to him. Personally he has had three cases in five years, and he knows of one or two cases which have been attended by other medical men in the locality, 13,423–8. He has seen one undoubted case of diphtheria in his own practice at Shooters Hill a few weeks ago, and one doubtful case; two other cases in the lower part of the town he saw when in consultation. He knows of no other cases, 13,429–30. Scarlet fever and other diseases of that sort he does not believe to be peculiarly prevalent, but they are not less prevalent than elsewhere, 13,431. He knows from personal experience, that the river smells badly, but he is unable to trace the diseases to the presence of sewage in the river, 13,432–3, 13,438–44. He traced one case of typhoid fever to defective sanitary arrangements in the patient's office in London, and the two other cases were due to the defective closet arrangements at the Becton Gasworks, where the men (father and son) worked. The cases were almost simultaneous, 13,434–6. The general health of the people of Woolwich is very fair; it is, as far as his practice enables him to judge, as healthy as most places, and he has never had any reason to believe that the river exercises any injurious effect upon the health of the district, though he has smelt it often enough. He has crossed the river frequently, but has no recollection of the smell being very bad in 1882, 13,437–40, 13,457. He lives on the common, a mile from the river, and has noticed the smells from the factories there, but never any smell from the river. He attributes the smell of the river to sewage, 13,441–50. The two cases of typhoid from Beckton Gasworks occurred in the winter, 13,451–2. Many poor people do not call in medical aid unless the illness is serious. For measles and diarrhœa a doctor is seldom called in, except in the case of clubs, when a doctor can be called in for nothing, and he is medical attendant to several; but there are not many scarlet fever cases unattended, 13,453–5. He would not like to express an opinion as to whether the injurious effect of the river would show itself principally in scarlet fever, measles, and diarrhœa, as Professor Corfield stated in his evidence, 13,456. He has had no illness himself from this smell, but many patients have had nausea and headaches, which they and he attributed to the smells from the factories. He never heard, nor have they complained, that it was due to the smell from the river, 13,460–1. He practised for a year and a half before he came to Woolwich, and he had one case of typhoid fever there. There was a considerable epidemic of typhoid at Hanwell before he practised there. Before going to Hanwell, he was in India, 13,458–9.

## Mr. WILLIAM WARMAN COLEMAN, M.R.C.S.

District Surgeon under the Factories and Workshops Act, 1878.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—On the night of the "Princess Alice" disaster, he was rowing about in a small boat examining all the people who were picked up, and on the next day he was on board the "Heron" steamer picking up the bodies, which were placed on board preparatory to being taken ashore. They were not particularly muddy, nor had they the appearance of sewage about them, 13,485–90. He has seen many cases of drowning, and bodies taken out of the Thames, are always more or less in a muddy condition, 13,491–2. Prior to his attention being called to this inquiry, he had never noticed the smell from the river, and since then he has tried to detect it by crossing the river at low water, but was surprised to find how little smell there really was, 13,493–4, 13,497–8. At times the smell from the factories in the neighbourhood is frightful, particularly at night when the wind is in the east or north-east, 13,495–6. He read in the daily papers accounts of what was being done in connexion with this Commission, and saw boats floating about with people taking samples of the water for examination. It is about two months since he was asked to give evidence on the subject He expected to find the river in a much more offensive state, 13,498–502, 13,531–3. He has sometimes noticed a very slight smell from the mud on the banks, but more frequently he has never noticed it, 13,503–4. In comparing the state of the bodies of the people drowned in the "Princess Alice" with others, they were mostly the bodies of people who had fallen into the river from vessels, or drowned while bathing, close to the Arsenal. He has not observed the condition of bodies taken from other parts of the river, 13,534–6. From the fact that those drowned in the "Princess Alice" disaster were in good health and in full habit of body, decomposition would set in more readily than it would in ordinary cases of death; the weather was warm at the time (September) which would assist decomposition, especially in the case of obese persons. After being submerged for two days, the latter would be in a very offensive condition. The bodies of those he saw were not black, but the faces were all turgid and bloated, as is invariably the case where animation is suspended suddenly, 13,537–9. He goes to the marshes frequently to see people who have moved in the direction of Erith from Plumstead, they having been old patients of his, 13,540.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He has lived for 26 years in Plumstead Road, Woolwich, which is about 200 to 300 yards from the river, and has practised as a medical man for the whole of that time. For five or six years he has attended the Arsenal, and as surgeon under the Factories and Workshops Act, he has constantly to visit the factories, &c., in the district, 13,462–9. Neither he, nor any of his family, have experienced any ill effects from living close to the river, 13,465. He visits a great number of people living on the river banks, and also the families of working men, and zymotic diseases are not prevalent amongst his patients, 13,470–2. Considering the enormous population, Woolwich (and Plumstead, which is a part of Woolwich) is a very healthy town. He has no statistics as to the death-rate, as there is no medical officer for Woolwich, 13,473–4. Part of Woolwich stands high, on gravel and sandy soil, and as regards zymotic diseases the lower part compares favourably with the higher. The greatest number of zymotic diseases have occurred at a place called the Slades, across Plumstead Common, which is the part most remote from the river. Whether due to defective drainage or not he cannot say, 13,475–6, 13,481. He has never known a case of zymotic disease produced by sewage in water, except when the mixture has been drunk. There were eight deaths amongst his patients in 1882, but none of these were due to zymotic diseases or blood poisoning, 13,477–9. The drainage of Plumstead Marshes has produced a very beneficial effect on the health of the people in the neighbourhood, 13,480. He has seen "mud-larks" playing in the mud near the Arsenal, and boys are constantly bathing there. Except from immersion and suspended animation when a boy has gone beyond his depth, no evil results have arisen, 13,482–4. Where sewage is poured in large quantities into a river, a deposit is formed upon the banks, which, when exposed to the sun, gives off poisonous emanations to the air, and so typhoid fever and scarlet fever may

## Mr. WILLIAM WARMAN COLEMAN—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

be communicated to other places, and so to people living on the banks. Against that statement, however, he mentions the case of a man who, with his family, has lived for 19 years at No. 1, Land Magazine, without any disease occurring. Zymotic diseases have been conveyed by sewer gas, and the germs of the disease are carried by means of the air, but he would not like to say that the same would apply to emanations from river banks under a hot sun. He believes it to be a moot point between the highest authorities, 13,505–19. He has not seen the Report of Messrs. Bidder, Hawkesley, and Bazalgette, upon this subject, and would, therefore, rather not express any opinion upon their statement, "the condition of the stagnant mud is injurious to health." He did not know until yesterday that he was to give evidence, and consequently has not prepared himself in any way, 13,520–2. He has not compared the death-rate in the parishes by the banks of the river with those not affected by the river, nor has he ascertained whether diarrhœa, measles, and typhoid fever are more frequent in the riverside parishes than in others, 13,514–5. A thing may be injurious to health without creating zymotic disease. There is a difference in the condition where gas is given off from a sewer, or where gas or vapour is given off from the banks into the open air, and so is diffused into an immense bulk of air, 13,523–6.

## Mr. F. LETT, M.R.C.S., L.R.C.P. Edin., &c.

District Medical Officer to the Woolwich Union.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He has lived for 11 years at Rectory Place, Woolwich, which is about a quarter of a mile from the river, and his practice is near the centre of the town. His district extends from the river nearly to the top of Woolwich Common, and he has many patients amongst the labouring classes employed on the river, and living both near, and on the banks of the river, 13,541–9. He has had no cases distinctly traceable to the presence of sewage in the river, and the general ratio of zymotic disease in his practice, as compared with the ratio of zymotic disease to other diseases in the country is comparatively low, 13,550–1. He has had cases of typhoid fever, diphtheria, diarrhœa, and scarlet fever, but he could not trace them to riverside occupations, 13,552–7. He has had opportunities of judging the sanitary condition of the river, but he has never been able to trace any deleterious effect upon the health of the inhabitants arising from it. In his opinion the general health is very fairly good, 13,558–60. He has smelt the sewage in the river in hot weather, but is uncertain whether he noticed it in 1882. He cannot trace any disease arising from the deposit upon the banks of the river, whether zymotic or otherwise. He would not like to say whether sewage in water (not drains) could create zymotic disease, 13,561–5. The smells from the factories are very disagreeable and offensive, but he would not like to say that they were productive of disease, 13,566–8. He has had no complaints from people suffering from nausea or diarrhœa arising from some unexplained cause which would cause special remark on his part, but the smell from the river, which he has noticed, would be very unpleasant to persons already in ill-health, and might be to a certain extent injurious, or of a prejudical character. He has, however, no knowledge of any such cases either in his own district or elsewhere, 13,569–71, 13,585–9. He has never been able to distinguish whether the district away from the river is more healthy than that part nearest to the river. Had such a difference existed, he would have noticed it, 13,572–4. There has been no prevalence of diseases near the river which have their origin in bad air and water in his district, 13,575. Most of the cases of typhoid fever, diarrhœa, and measles in his district have remained untraced, 13,576–7. The people living on the river banks are, as a rule, poorer than those further away, and receive medical attendance gratuitously. In cases of any diminution in *vis vitæ*, referred to by the Vicar of St. Nicholas, Plumstead, they would in all probability call in the medical officer of the union, as he can order them, besides medicine, other things much desired by the poor, such as aliment, 13,578–84.

## Dr. ALFRED ROWARTH.

Medical Officer to the Training Ship "Exmouth."

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—The "Exmouth" is stationed off Grays, at which place he lives, and goes on board every day except Sunday. He therefore has opportunities of judging of the state of the river, 13,590–4. He has never seen any traces of sewage in the river, nor observed any smell from the water. He has never noticed any smell of sewage on the banks, the only smell being that of mud banks in general, 13,595–8, 13,611–15. In the summer months a bath on board the "Exmouth" is filled with river water in which the boys bathe daily, and he also has bathed in it, which he would not do if he thought there was sewage in the river at that point, 13,599–602. There is nothing perceptible in the state of the water to lead him to suppose that sewage was discharged higher up the river, 13,603. He has been connected with the "Goliath" and "Exmouth" for 11 years, and there are between 500 and 600 boys on board the "Exmouth," 13,606–7. The smell from the mud is an earthy smell, and is totally different from a sewage smell. He could detect the difference immediately. The smell from the mud is not unpleasant, 13,614–5. The "Arethusa" is moored off Greenhithe, and the "Cornwall" is stationed off Purfleet. The smell of the mud is very bad there (at Purfleet), but he does not know anything about Greenhithe. The river is not so clear at Purfleet as it is at Grays, 13,616–21. There is no bathing at Gravesend now, because there is no convenience for it. He has bathed at Grays upon the lowest ebb tide, but prefers the top of the flood, because the water is salter and clearer, 13,622–8. The health of the boys on board the "Exmouth" is very good indeed, and fever and diarrhœa are distinguished by their absence. Boys are received on board from 11 years to 15 years, and there are between 500 and 600 of them on the ship. When admitted first they are not healthy boys, 13,604–10.

## Mr. HENRY LAW, M. Inst., C.E.

Member of the Council of the Sanitary Institute of Great Britain, and Fellow of the Meteorological Society.

His first acquaintance with the Thames, commenced in 1837, when he was articled to Sir Isambard Brunel, who was then constructing the Thames Tunnel. The nature of that work rendered it necessary that the should make himself acquainted with the movements of the tide and the conditions of the river-bed, and he had to watch the tides carefully and make daily observations on the river, 13,629–33. He subsequently became chief assistant to the late Mr. Thomas Page, and he made the working drawings for Mr. Page for Westminster Bridge. In 1843 or 1844 he prepared plans for the Thames Embankment, and took soundings and made 61 sections of the river to compare with those taken by Mr. Telford in 1823 to see what change had been occasioned by the removal of London Bridge, 13,634–40. He has also prepared plans for the construction of Charing Cross and Lambeth Bridges, and superintended the building of the Victoria and Albert Bridges over the Thames at Windsor. He has, therefore, acquired an intimate knowledge of the Thames, 13,641–2.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He begins by quoting an extract from page 11 of the paper laid before the Chemical Society on River Water, by Dr. Tidy, and its capability of purifying the sewage discharged into it. He has made a calculation to enable him to tell what proportion of pure water there would be to receive the sewage poured into it at the outfalls. He produces a diagram (*see Appendix B. O.*), upon which the heights are plotted to the tenth of every tide, and he finds that the quantity of water coming ever Teddington Weir on the 3rd October 1882 between high and low-water was 61,900,000 cubic feet. The quantity of water in the river flowing out between high-water and low-water at Crossness was 2,523,000,000 cubic feet, which gives a total of 2,585,000,000 cubic feet passing between Barking and Crossness on that tide. The sewage discharged in one tide is 9,894,000 cubic feet; and that bears a ratio of 1 to 261 as compared with river water, which is 13 times the quantity Dr. Tidy considered necessary to purify the sewage, except that it must be borne in mind that the water, Dr. Tidy said, was already contaminated

## Mr. HENRY LAW—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

with sewage, 13,855–61, 15,157–65. Unless, therefore, the river contains the unaltered sewage of 12 tides, that volume of water would be competent to purify the sewage, 13,862–3, 15,157–65. On the 14th September, when it is stated that the water in the river was more impure than on the other days when the samples were taken, he finds that the water at North Woolwich was nearly as pure as the drinking water supplied to the inhabitants of London, and, therefore, capable of purifying the sewage which was delivered to it in the proportion of $\frac{1}{260}$th part of its bulk. At low-water on that day, the water in the river at North Woolwich might have been drunk with impunity and without disgust. It was a day or two after spring tides, when the overflow is greater than the inflow, and the sewage does not come back so high up the river when the tides are taking off, 13,863–74. 15,114–25. With reference to Professor Way's statement (Q. 12,289) that 100 tons of oxygen were required to oxidise the sewage, and if it were possible that the whole of the sewage should be burnt up day by day as it went in, the air of the neighbourhood would be irrespirable, the stock of oxygen being exhausted. Now he has made a calculation to test that statement. The sewage he admits travels about 12 miles down and 11 miles up the river as a rule, and the mean superficial area of the river for 12 miles below Barking is 151,000,000 square feet, and each cubic foot of air contains 123 grains of oxygen, so that a layer of air only one foot thick would contain 1,189 tons of oxygen. So for the 11 miles back there would, at the same rate, be 1,093 tons of oxygen, making 2,282 tons of oxygen, or 46 times the quantity required. If the sewage did not take up the oxygen for more than a foot, it would not affect the atmosphere in the neighbourhood. That shows how dangerous a thing it is to make random statements without making a calculation, 13,875–6. The cubic foot of air above the surface he uses as an illustration only, not as a fixed quantity, 13,879. Again, water contains two cubic inches of oxygen to the gallon, and will not absorb more. But if any of that quantity be extracted the water sucks it in from the air with avidity. From the tables of analysis the water is shown to contain an inch of oxygen on the average at the outfalls (and an inch weighs ·3438 of a grain), it contains, therefore, 354 tons of oxygen, which is seven times the quantity required before it has to take any from the atmosphere; and, as at Erith, the water is found to contain ·42 of an inch, the inference is that the balance has been used in burning up the sewage. It is the exhaustion of the oxygen in the water that kills the fish in the river, 13,877–8. A good deal has been said about the pure state of the water many years ago as compared with its present condition. When he was engaged in constructing the Thames Tunnel, serious inconvenience was caused by the character of the ground which came from the bed of the river into the excavations, poisonous gases and inflammable gases came into the shield and caught fire, burning for a considerable time, and the health of the men was affected by these emanations, 13,959–60. In 1839, before all the sewage was turned into the river, the houses were drained into cesspools, and it was an offence at common law to carry the overflow from a cesspool into the sewer, and it was not until Bramah invented the watercloset that the connexions were made surreptiously, and at last they were made so extensively that the law was altered, and from being prohibitive, it was made compulsory, 13,961, 15,175–80. A lengthy description of the state of the river will be found in the First Report of the Thames Conservators issued in 1858, and in Mr. Farday's letter to the Lord Mayor in the same year complaint is made of the condition of river. He also calls attention to the joint Report, dated 15th April 1878, of Sir J. Bazalgette, and Messrs. Law and Chatterton, 13,962. If he had the power, he would not take the sewage 20 miles further down the river, but if he could do it for nothing, he would not hesitate to discharge it into the sea as he has always advocated that measure. It is no nuisance where it is, because he believes that, if people were ignorant of the fact that the sewage was discharged into the Thames, no person passing up and down the river would ever find it out unless they went within 100 yards of the outfall itself, 13,966–73. While the sewage is not practically appreciable, there exist intolerable stenches from the factories, and from barges with putrid bones. He has seen clouds of smoke and

steam, within the last six months, proceed from the works of Messrs. Odam at Bow Creek which obscured half the river, and the smell from the salicylic acid was intolerable. The stench from the bone barges is so nauseous that it is impossible to conceive anything more offensive. These are nuisances, but he really considers the nuisance of the sewage inappreciable, 13,973.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THN MAIN OUTFALLS.—He has given some attention to the subject of deposits in the river, and the Thames must be a muddy river, for no river under the conditions of the Thames can be otherwise than muddy. The traffic is so large, and the water is kept in such continued agitation, that it is impossible for the mud to settle, 13,880–2. Dr. Frankland put in a report with copious tables, which showed that upwards of 1,000,000 tons of solid suspended matter were discharged into river from the outfalls every year. Now Table B, which deals with this question, contains several errors, and these inaccuracies affect the average. In one case the rain falling was described as "very slight "rain, not measurable," whereas on inquiry he found the amount of rain fall was $\frac{1.5}{100}$ths in 18 hours, or nearly the maximum amount that provision was made for in the sewers. Again, he cannot find in Messrs. Hoffman and Wilt's Report any statement that there are 209 grains of solid matter in each gallon discharged, as quoted by Dr. Frankland. The value of these tables is destroyed, owing to the fact that when these observations were taken in 1857, the system of sewers was totally different to that now in existence, 13,882–6. He further disputes Dr. Frankland's statement that $\frac{1}{100}$th of an inch of rain in 24 hours would increase the flow of sewage at Barking by 14,000,000 gallons, and the proportion of solid deposit in every gallon would be increased from 23 to 42·9. Now not a drop of such a rainfall would ever reach the sewers, 13,887–90, 15,126–8. Mr. H. Leach, when before the Mud Inquiry Commission, stated that the whole of the mud in the river came from the sewers. Now he contends that the mud washed from the banks and the saltings by the wash caused by the passage of large steamers, which are yearly increasing in size, speed, and number, up and down the river, contributes principally to the muddy state of the river, and also that this said mud contains matter in it as noxious as the mud found at the bottom of the river. Another thing that helps to wash away the banks is, the increase of two feet in the height of the tide since the removal of old London Bridge, 13,890–902. The banks in the higher reaches of the Thames are being destroyed also by the steam launches, and the reports of Colonel Bolton show how large a quantity of detritus is washed over Teddington Weir, 13,902–6. If the sewage were shut out of the river altogether, there would be no tangible difference in the quantity of mud deposited on the mud banks. He produces Plan No. 19 of a large salting in the river at Broadness (*see* Appendix A.E.) to show the manner in which the saltings break down. The total length of river bank from Kingston to All Hallow's and Teddington to Yantlet is 133 miles, 43 miles of which in 1879 were unprotected, 13,907–8. He hands in Diagram No. 34 (*see* Appendix B. M.), which is plotted from observations taken jointly by Mr. Keats and Dr. Tidy for a month to ascertain the quantity of water flowing over Teddington Weir, and of the quantity of suspended matter in that water. On the 7th February when there was no rain, the amount of suspended matter was only ·18 in a gallon, and only five or six tons came over altogether. On the 21st February, in a time of rain, the quantity of water increased by six times, the suspended matter was 24 grains, and the total quantity of suspended matter was 4,666 tons. The table is contained in the Mud Inquiry Report, 13,909–11. His next proposition is that in a river so laden with mud, if there is slack water, mud must be deposited there. He produces sections of the river taken in 1796, in 1823, and in 1843, in which the places where the water has deepened is coloured blue, and where shoaling has taken place, the sections are coloured red. Above London Bridge it is all blue, while below all the sections are red down to Blackwall Point, which is as far as he has taken these sections, 13,911–20. He hands in Diagram No. 18 (*see* Appendix B. L.) and Diagram No. 35 (*see* Appendix A. Z.), 13,921–22. Many of the changes and banks have arisen to a great extent from the system of artificial dredging which has been carried on since the appointment of the Conservators in 1858. Prior to that, the Trinity Corporation dredged for ballast only, but the Conservators have used extremely powerful dredging machines, and have even resorted to the use of gunpowder to break up iron bound gravels which formed shoals or shelves. A great improvement in the navigation of the river was no doubt effected, but the result has been to increase the section of the river and to diminish the velocity, causing a deposit. He hands in Diagram No. 6 (*see* Appendix B. A.), and Diagrams Nos. 7 to 13 (*see* Appendices B. B., 1 to 7), showing the commencement of the formation of the shoals in the neighbourhood of the outfalls prior to the outfalls being put there. An examination of these sections will show that where dredging was, deposit takes place, and that the deposit was the nucleus of the banks of which complaint is made. He hands in Table 9, giving a comparison of the velocities of the ebb stream at half-ebb of an average tide in 1861 and in 1864, in feet per minute, 13,923–6. He hands in Plan No. 5 (*see* Appendix B. C.), showing by brown spots where mud was shown to exist in 1861 by the Conservators in Erith Reach and Erith Rands, 13,926–7. He hands in four coloured plans showing the form and depth of the channel in the same part of the river from soundings taken in the years 1831, 1861, 1879, and 1882. He hands in (*see* Appendix B. E.) a table No. 10, which is a resumé of the contents of Plan No. 20 on a small scale, showing the low water capacity of Divisions 2, 3, and 4 of the Thames derived from soundings in the above mentioned four years, and giving the percentage of increase of the total contents of the channel, 13,927–30, 15,129–56. He hands in Diagram No. 21 (*see* Appendix B. F.), which is a longitudinal section of the river from Teddington to Gravesend, showing by means of blue lines the surface of the water half an hour before the middle of the ebb, and half an hour after middle ebb. By this means, the quantity of water passing any point during the middle hour of the ebb tide can be accurately ascertained, and having the transverse sectional area, the velocity can also be ascertained. He hands in Table No. 11, showing the mean velocities of the current in the river Thames between Blackwall Point and Long Reach during the middle of the ebb tide on the 3rd October 1882. It is compiled from sections plotted by Mr. Shelford, Mr. Mansergh, the Metropolitan Board of Works, the Thames Conservators, and Messrs. Law and Chatterton in the years 1877, 1878, and 1879, 13,930. Diagram No. 17 (*see* Appendix B. G.) shows the lines of the respective sections; the horizontal line A. A. is put at an altitude above the datum line which represents a mean velocity of 196 feet per minute, or 2¼ miles an hour, as about that which would keep the river clean. The parts coloured pink show where the velocity is too slow, and the blue parts where the velocity is high. If the velocities rise and fall and they are assisted by the river being tortuous and of varying width, deposit is inevitable, and is the natural result, and is not the result of accidental proximity of those places to the sewage outfalls, which are quite inadequate to produce the result even of those shoals alone. Diagram No. 14 (*see* Appendix B. H. (1,)) shows the low-water sectional areas between Jenningtree Point and Dartford Creek in 1833 and 1861, and it will be seen that the sectional area has increased exactly where the mudbanks are complained of. Diagram No. 15 (*see* Appendix B. H. (2.)) gives similar details for 1861 and 1879. Diagram No. 16 (*see* Appendix B. H. (3.)), on being compared with the previous diagram, shows that the places where the sectional area is diminished, as shown by the brown spots, are just the same as the spots where it had been made abnormally large, 13,930, 15,129–56. In midstream off Erith Pier, there is a very large mudbank, which has been deposited by the water on the south side. No doubt the water had its due admixture of sewage, and contributed its share to the bank as adding to the solid matter to the river, but he will not admit that the banks are partly formed of sewage. Some part has been contributed by the outfalls, but it is not right to assume that that is sewage because it came out of the outfalls. Sewage may be divided into two parts, the perishable and that which is permanent, and it is the latter only which contributes to the banks. The ratio of the sewage to other matters is so small, that the effect is inappreciable. If there had been no sewage in the river there would still have been a deposit of mud in the bed of the river, 13,935–47. On

Mr. HENRY LAW—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

the 30th April 1839, when constructing the Thames Tunnel, a considerable rush of ground took place, bringing with it every description of river deposit and dirt, a root resembling a seaweed in a fresh state, oyster shells, &c., accompanied by a very strong effluvia. The stench in clearing out the frames was horrid, the ground thus removed was black mud, river deposits, small coals, and masses of black clay. That was the nature of the bed of the river in those days before the sewage was turned into it, 13,960–1. In 1872 he went down the river accompanied by the Commissioners on the mud inquiry, and dredged up mud wherever they pleased, including the bank opposite Crossness, which it is alleged consists entirely of sewage. The whole of the mud so brought up was of a perfectly inoffensive nature, and not a single sample of offensive mud could be found, 13.962. When the Dagenham shoals were removed the river was larger in its section in Halfway Beach than the cross section below was originally, and on Mr. Mansergh's section made in 1878, the accumulation of mud is shown with a consequent constriction of the river at this point. He does not know that in 1882 it had become still smaller, and although so shown on Mr. Mansergh's diagram of 1878, he cannot say that it is not correct. He does not think that section could have been taken before the shoal was removed. Assuming that it becomes smaller, it does not follow that that deposit must be of such a character that if the floods should sweep it away it would re-deposit in the ordinary currents, because where the largest accumulation has taken place, the velocity of the current is even now far to weak. Although there are one or two points where there is a stronger current for a short distance, it is not sufficient to affect the deposit upon the south side, 15,129–42. The cross-sectional area of the river before the Dagenham shoal was removed at half ebb was about 40,927 square feet, and the actual area now is between 56,000 and 58,000 square feet, as will be seen on reference to Diagram 10. He will furnish the exact area, 15,143–56. He has not gone into the chemical composition of the mud at Erith. It has no smell at all except of earth, even on warm days, unless it is stuff taken out of the sewers which trickles over the surface, 15,173–4. Since the last meeting of the Commission, he went down the river and took samples of the mud at those places where it had been described as being "derived from the human frame." Although the weather had been dry and warm for some time, there was no smell in it whatever, except the ordinary smell of mud. The samples were taken at low-water, 15,187–92. He is now able to give the area of the Crossness section on the line D. D, asked for (*see* Q. 15,143–6). In 1833 the sectional area at low-water was then 20,445 square feet; in 1861 it had been enlarged to 33,780 square feet; in 1864 it had diminished to 28,770 square feet; and in 1879 it had been increased to 33,850 square feet, 15,703–4.

Effect on Wells near the River.—He calls attention to Mr. Latham's statement that the discharge of sewage into the river is likely to affect the wells in the neighbourhood (Q. 7944), and he wishes to point out that the water which exists in the chalk stands at a very high level of 400 feet at a distance of some miles from the river, and falls with a gradual gradient towards the river, from which it is plain that the water will run from the wells into the river, and not from the river into the wells. If there are any wells where the water stands at a lower level than the high water in the Thames, it proves that some impervious stratum of clay exists between the well and the river, thus cutting off access to it, otherwise the river water would reach its level in the wells. The cause of the rise and fall of water in the wells with the tide is due to the increased pressure of the tide, which prevents the chalk water escaping, and so fills up the wells, 13,962–5.

Distribution of the Sewage in the River by the Various Motions of the Water.—In the Thames water there are four elements, viz., the upland or surface water draining into the river; the spring water, which finds its way into the bed of the river through the springs; sea-water; and sewage. The spring water up to the present time has been ignored in considering the question of dilution of the sewage, 13,720. In considering this part of the question, it is necessary to ascertain what it is reasonable the river should deliver, comparing the upper and the lower. He therefore

Mr. HENRY LAW—*continued.*

Distribution of the Sewage in the River by the Various Motions of the Water—*continued.*

ascertained first the quantity of water abstracted by the water companies. The water abstracted above Teddington amounts to 7,778 cubic feet a minute, which must be added to the quantity gauged by Mr. Latham as coming over Teddington Weir if it had not been abstracted. The East London Water Company abstracts 2,444 cubic feet per minute from the Lea, and the New River Company takes 5,868 cubic feet per minute from the underground springs at Amwell, making a total of 16,090 cubic feet per minute for the water supply. The mean discharge over Teddington Weir from the 7th September to the 30th November was 338,488 cubic feet per minute, which, with the 7,778 cubic feet, gives a total of 346,266 cubic feet per minute draining from the 3,676 square miles of country above Teddington, or 94·2 cubic feet per minute per square mile. Below Teddington the mean discharge is 61,709 cubic feet per minute, and, adding 5,868 cubic feet, gives a total of 70,021 cubic feet per minute for the 1,486 square miles below Teddington, or 47 cubic feet per minute per square mile. From this it will be seen that the quantity of water delivered from each square mile above Teddington is double the quantity from each square mile below Teddington, 13,726–30. This agrees with Mr. Latham's statement. Now, in Mr. Symon's tables of rainfall (in which he has corrected a few slight inaccuracies) the quantity of rain which fell during three months in the upper basin of the Thames amounted to 13 inches, and in the lower to 11¼ inches. To arrive at a reasonable result, these relative rainfalls must be discounted, for, assuming the geological conditions to be the same, and supposing the surface of the ground were of a similar character and would allow all the rain to run off, then the quantity of flow which would be gained at Teddington would bear to that which would be obtained in the Lower Thames the proportion that the rainfall bore in the one to the other. That being so, 121,230 cubic feet a minute should be delivered below Teddington instead of 70,000 cubic feet a minute as gauged by Mr. Latham, the excess of 51,209 cubic feet being due to geological conditions and the character of the country, &c., 13,731–40. Now, the reason of this difference between the quantity of water coming over Teddington and the quantity below as gauged by Mr. Latham is due to the very large quantity of water which finds its way into the Lower Thames through its bed by springs, and it makes a very important difference indeed in the ratio of the upland water to the lower. On the Ordnance map which he hands in (*see* Appendix, B. P.), he has coloured the outcrop of the gault, which upon the line coloured blue is from 200 to 800 feet higher than the level of high water. In Kent it is sufficiently high to form a basin, and descends to a depth of 600 feet below the sea level, and it is perfectly impervious to water. The chalk and gault run beyond the Thames Valley towards the sea, but owing to the incline of the strata, the water falling on the chalk finds its outlet in the valley of the Thames. The whole surface of the chalk is singularly free from rivers, but numerous "swallow-holes," as they are called, exist, absorbing enormous quantities of water, the 5.868 cubic feet per minute pumped up by the New River Company being only a portion of that water, 13,741–4, 15,182–6. Immediately above the gault and forming the green line is the upper green sand; the pink portion of the plan is the outcrop of the tertiary beds which are pervious to water, and the grey is the London clay, which is impervious; so there is an enormous reservoir of water imprisoned between the London clay and the gault; this tends to prove that there is a large quantity unseen of water which enters the Lower Thames and which has not been estimated, 13,744–51, 15,182–6. He hands in sections, Nos. 27 and 28 (*see Appendices, A. S.* 1 and 2), which were taken more or less at right angles to the course of the river through the Thames Valley Section. No. 27 is from observations taken a year ago by him for another purpose. The names of the places where wells extending to the chalk were dipped at intervals show the level of the water, and it will be seen that at Tring the water stands at 453 feet above the Thames, and then falls gradually until at Isleworth it is at the level of the Thames. It is always being supplied from above, and it is always escaping either into the bed of the river or the sea, 13,751–2, 13,757–62, 15,044–6, 15,182–6, 15,194. The total area of the Thames basin is 5,162 square miles, of which he lower tertiaries, the chalk, and the upper green sand

MR. HENRY LAW—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

(all of which are pervious and admit the rain) contain upwards of 4,000 square miles of country, and which absorbs a large proportion of the rain which falls upon it. In many parts, where either the gault or London clay meet the chalk, the rivers which had been formed upon less pervious strata disappear, being absorbed by the chalk. These "swallow" or "swilly" holes exist to a large extent in the River Mole between Dorking and Leatherhead, and they also exist at Canterbury. Farnham, Newbury, and Hungerford; and also in the valley of the Lea between Barnet and Hatfield there are a series of streams or rivers which have no outlets whatever, but disappear, and are the feeders of the Amwell Springs. He has coloured these on the map as they exist (*see* Appendix B. Q.). They have no outfall whatever into any river, and so could not have been gauged by Mr. Baldwin Latham. They come to an end at South Mimms and Mimms, 13,752–6, 15,033–73, 15,077–82, 15,194. Full particulars of the geological formation of the Thames basin, the swallow holes, and the escape of the rain and surface-water into the Thames and the sea are to be found in Mr. Prestwich's paper, volume 10, (in the Proceedings of the Geological Society, page 222; in Mr. Long's paper, volume 3, page 101; and in Mr. Clutterbuck's paper in the Journal of Royal Agricultural Society, volume 25, page 306, 13,757–63. He wishes to call attention to the fact, which is important, that the water-levels during the whole of the year in section 27 varied from ·58 of a foot near the Thames to 18·9 feet near Tring. The water in the chalk varied with the season, with the rainfall below that height, so that the hydrostatic head was a little greater at some times of the year than at others. In Mr. Barlow's paper, read at the Institution of Civil Engineers in December 1854, it was suggested that the large quantity of water running through the chalk into the Thames should be intercepted for the supply of water to London, and mention is made therein of the visible springs in the river. These can be seen near Greenhithe at near low water, and he has seen them himself, 13,762–5, 15,192–3. Gault is a very strong clay, almost of the consistency of marl, from which gault bricks are made, 13,766. He hands in a Diagram. No. 29 (*see Appendix A. U.*), which expresses Professor Way's determination of chlorine. The lines express as ordinates the quantity of chlorine, and they become elevated at Erith, instead of being continuous, as they would have been if the chlorine had been a mean quantity, in consequence of the spring water entering there, diluting the sea water and making it more fresh, 13,766, 15,195–6. He points out that Mr. Mansergh has over-estimated the quantity of sewage from some unexplained cause to the extent of nearly 10 per cent. over Mr. Latham's estimate, which is in itself too high, though more exact than Mr. Mansergh's. Mr. Latham took the population and the estimated water delivery at 31·5 gallons per head, which gave, according to his calculation, 16,296 cubic feet a minute. Mr. Mansergh calculated the quantity to be 18,055 cubic feet, whereas he makes it to be 13,742 cubic feet, taking 5 cubic feet, which is equal to 22·5 gallons per day. The difference is an important one. In estimating the quantity of upland water, he finds Mr. Latham and Professor Unwin erroneously stated that the quantity of water passing over Teddington Weir produced an immediate alteration at Crossness, and that the water runs out at the other end as fresh water. This, he contends, is not the case, as it becomes mixed with what is already in the river, and it takes a considerable time to run through. The effect of pouring a large quantity of water into the upper end of a channel of considerable length with water flowing through it is to increase the inclination of the water, and gradually to increase the velocity all the way, 13,766–70, 15,082–6. Now, he says, by taking the quantity of water gauged by Mr. Latham as coming over Teddington Weir upon the 7th September, instead of the 14th September, he gets 144,824 cubic feet per minute instead of 118,000, which makes a considerable difference with regard to the relative volumes of sewage and land water. If from this amount the water supply be deducted, and the deficit of 51,000 cubic feet, which there was between Mr. Latham's gaugings of the Lower Thames as compared with the Upper Thames be added to the amount, it amounts to 193,683 gallons, which has the effect of reducing the per-centage of sewage to upland water, estimated by

MR. HENRY LAW—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

Mr. Mansergh at 15 per cent., to 7·1 per cent., making a difference of cent. per cent. This difference affects a very delicate chemical test which was made at Crossness to ascertain the quantity of sea-water in the river, because by means of chlorine that can be determined. If then they assumed that on the day the test was made the amount of upland water was 118,000 cubic feet instead of 144,000 cubic feet, which came over Teddington Weir a week before, there was so much more left for sewage, which gives an incorrect result, 13,770–95, 15,166–72. He will now deal with the chlorine test itself. The witnesses for the Corporation of London assumed that the sea-water which enters the Thames from the North Sea always contains 1,961 parts of chlorine in 100,000 parts, and if a less quantity of chlorine was found in 100,000 parts in any body of water, the difference is upland water and sewage in the river. This he contends is too high an estimate, because they never found so large quantity, and the North Sea receives all the drainage of fresh water from the east coast of England and also the whole of Western Europe, and consequently the water must be far less saline than the Atlantic Ocean, 13,782–4, 13,795–6. Supposing their assumption was correct, the result would show a much smaller quantity of sea-water than was actually present. His reason for going into this matter is that it is one of the grounds on which the alleged pollution of the river to the degree it is said to be polluted is based. On the 14th September, the whole body of the river was said to contain 11·7 per cent. of sewage, nearly an eighth of the river in fact, which would be a very serious matter, and the quantity of fresh water that comes in as compared with the sewage with which it is mixed can be ascertained with certainty, and that is just where this estimate of the spring water and so forth has such a very important bearing upon this question. His view corroborates his notion of underground supplies, 13,797–804. Professor Way in his Table No. 2, gives an analysis of the sea-water at Margate upon several days, the highest being 1,951, the lowest 1,737, and the mean 1,899. Dr. Frankland gives in his Table No. 3 the mean of the sea-water at Brighton, Penzance, and other places as 1,900, while in mid-Atlantic he gives only 1,800, therefore to attribute any deficiency in the amount of chlorine in the water coming in from the North Sea to the upland water, containing sewage, is an assumption which cannot be borne out, 13,804–5, 15,085–90. He points out that the method of taking the samples of water for chlorine tests does not give a fair representation of the composition of the river, because the quantity of chlorine varies greatly at small intervals of time and within short distances. For example, the depth of the river between Gravesend and Southend, in some places is 80 feet, and to take two samples at 20 feet deep at Erith and two samples at Southend at the same depth cannot give a fair representation of the quantity of chlorine throughout the whole length of that section of 27 miles with sufficient exactness to enable anyone to say positively what is the composition of the water, and to determine that so much is sea-water and so much sewage. Yet that is the proposition that has been laid before the Commission, 13,805, 15,195–6. He has prepared a table which shows the variations which occur in the composition of the water as regards chlorine in very short distances. This Table No. 8 he hands in, and it gives the localities, the date, the state of the tide, the number and position of the sample, the amount of chlorine found, and the per-centage of difference between two samples taken within short distances and at small intervals of time. They vary from 10 per cent. up to 36 per cent. One sample taken at Erith on the 27th July, varied 20·6 per cent. between the surface and the bottom. The variations do not appear to follow any regular rule, but they are very much disturbed by the spring water coming in, and in some places also by the depth, or the set of the tide coming in, 13,805–9, 15,195–6. He hands in Diagram No. 32 (*see Appendix A., X.*) Mr. Mansergh, in Table M., 3 *d.*, (see column 10 added up) shows that on the 30th November at low tide, there were 297,600,583 cubic feet of sewage in the river between Southend and Woolwich, while the total upon the subsequent flood tide, *no sewage having been admitted into the river in the interim*, (column 10 being added up) amounted to 405,683,709 cubic feet, making an increase of 108,073,126 cubic feet, which is equal to the whole sewage of London for 5½ days. These quantities Mr. Mansergh

MR. HENRY LAW—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

obtained by ascertaining the quantity of chlorine in the river. If, therefore, this amount of sewage was actually in the river, it must have been brought back by the sea. It is alleged that there were seven or eight days' sewage in the river at low water, but that at high water there were 12 days' sewage in the river. The river at low water contains about half the quantity it contains at high water, and the proportion the increase in the quantity of sewage bears to the total quantity is 36 per cent., 13,809–29, 13,831–2. He considers Mr. Mansergh's statement is physically impossible. Diagram No. 32. which he has just handed in, shows the way in which the mean of the chlorine was taken. The amount of chlorine at the surface, and at 20 feet below were added together and divided by 2, giving what is called the mean. Now if the water increased in saltness from, say 290 grains at the surface to 338 grains at 20 feet below, they have assumed that the water was as fresh at the bed of the river as it was at the surface, instead of increasing in the ratio that it did between 1 and 20 feet, and when a depth of 80 feet is obtained in a length of 27 miles of river with all its varying circumstances, and trust to an observation at each end to give the quantity of chlorine, he thinks that observations founded upon that slender basis are not sufficiently accurate to draw such very important conclusions from, 13,830. He now comes to the quantity of chlorine in the river water and the sewage mixed. The opposite side have in their estimates taken the river water as containing 1·7 parts of chlorine in 100,000 parts, but the water which enters by springs through the chalk, (especially when it comes from underneath the clay) contains from 30 to 5 parts of chlorine in 100,000 parts. He takes the mean as 10· as against 1·7, so if the water coming over Teddington Weir, which he alleges on the 14th September was 128,734 cubic feet per minute, be taken at 1·7, and the 51,000 cubic feet from the springs at 10, it gives as the mean 4 parts of chlorine in 100,000 instead of 1·7. The chlorine test theoretically is perfectly correct, and given accurate quantities to deal with, which express the mean values, you get an accurate result; but if you apply the principle upon this basis, you will get a very different result, 13,832 The quantity of chlorine in some of these springs of chalk water has been arrived at by actual analysis, and is to be found at page 103 of the Sixth Report of the Rivers Pollution Commission. At Witham, in Essex, which is one of the points of outlet, the chalk water in a well close to its outflow into the Thames has been analysed; Professor Way analysed the water at the South Essex Waterworks, which are close to the point where the water flows into the Thames, and found 13·3 to 13·6 parts of chlorine in 100,000, and at Braintree the quantity is 38·8. It usually contains 15 parts, the mean being 10. The water as it flows into the Thames has never been analysed, but it could be. The other side took their samples from the water flowing over Teddington Weir, which gave 1·7 parts of chlorine, 13,833–45. Pursuing the same calculation as that adopted by Mr. Mansergh in Table M. 3 *b.*, in the division below Crossness, he finds the percentage of sewage in the river on the 14th September is 4·19 instead of 8·9 per cent., which is again about cent. per cent. difference. He points out various discrepancies in the estimates of Mr. Birch and Mr. Mansergh Mr. Birch's average of the whole length of the river being in excess of Mr. Mansergh's estimate by 16¾ per cent., whereas Mr. Birch brought his diagram forward to confirm Mr. Mansergh's. The absolute quantity of upland water and sewage as given by those gentlemen differs from 1½ per cent. less in the third division to 20 per cent. more in the fifth division. The percentage of sewage to upland water varies from 4 per cent to 20¾ per cent. Mr. Mansergh assumes that the quantity of upland water from Erith downwards is always constant, while Mr. Latham makes it increase on the 14th September by nearly 7 per cent. Mr. Mansergh makes the quantity of upland water and sewage in column 9 constant every day for 27 miles of the river below Erith. He makes it the same at Southend as at Erith, the same at high as at low water. Now it is absolutely impossible that the proportion of upland water to sewage should never vary during the 24 hours; that whether at Erith or Southend, whether the sewage has been discharging into the river, or the sluices are shut, the percentage of sewage to upland water should be always the same, is quite impossible, 13,846. He hands in Table No. 8*a* showing the difference between

MR. HENRY LAW—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

Mr. Birch's and Mr. Mansergh's estimates of the sewage in the river below Crossness, to which he referred in his previous evidence. Mr. Mansergh's estimates shows an average excess of 16·74 per cent. on the total quantity over Mr. Birch's estimate. It varies from 8·91 per cent. more in the first division to 44·04 per cent. more in the sixth division. The quantity of upland water as estimated by Mr. Mansergh varies from 1·36 per cent. less in the second division to 20·15 per cent. more than Mr. Birch's estimate in the fifth division; the average being 8·51 per cent. more. The percentage of sewage to upland water and sewage differs from 4·08 per cent. less in the first division to 20·77 per cent. more in the sixth division, 13,249. He now proceeds to make an elaborate calculation with regard to the chlorine tests shown by Mr. Mansergh's Table M. 3 *C.*, the result of which, he says, proves that if the slightest value is to be attached to that table, the upland water in the river was 40 per cent. in excess of the whole quantity of water in the river from Teddington to Southend. Practically the table must be wrong. Another circumstance which would appear to throw some doubt upon the chlorine tests upon the 14th September would be that they show that at St. Paul's Pier at high water there was 12 per cent. of sea-water in the river, which seems incredible, as only a few years ago the Lambeth Waterworks took nearly the whole of their supply from a point very little above this spot, 13,849–54, 15,095–105. He points out further discrepancies between the estimates of Mr. Birch, Mr. Mansergh, and Professor Unwin, as to the amount of sewage, and the total volume of water, in the river, 13,854–5 Plan No. 30 which he hands in (*see Appendix B. J.*) shows by actual experiment with a float the course of the current. The float he used was different to those used by the Conservators which were too heavy to be amenable to the small variations of the current. He produces this float and explains it. Plan No. 30 refers only to the experiments made on the ebb tide. At Erith there is a considerable eddy owing to the river being abnormally large at this part in consequence of the extensive dredging going on. While the tide runs down with considerable velocity on the north side the yachts moored in Erith Bight have their heads in all directions, 13,930–3. He hands in Diagram No. 36 (*see Appendix B. K.*) which gives the float experiments on the flood tide. One float put into mid stream opposite Erith Pier only moved 300 feet in six minutes, which showed that in the Bight there was slack water at both ebb and flood, the tide keeping on the northern shore always, 13,933–4. He refers at some length to Mr. Baldwin Latham's evidence in regard to the float experiments, and contends that although the float, No. 3, arrived at Chiswick after 12 days' travel in consequence of the continued oscillation, the sewage could not have travelled up so far. He does not deny the *bonâ fides* of that experiment, but he is aware of what happened to it. He will not, however, pursue that subject any further, 13,947–58. His statement that 3,794 square miles of chalk drain into the Thames is taken from Mr. Prestwich's book on the Water bearing Strata about London, which he produces. The areas of the Orwell, the Stour, the Colne, the Blackwater, the Cam at Cambridge, the Little Ouse, are not included in the 3,794 square miles. The 4,000 square miles he obtained from the same source. Page 59 in the book gives the figures he has quoted, 15,047–62. Some extracts are read from Mr. Prestwich's book with a view to show that Mr. Law had picked out some streams which do not drain into the Thames, making a difference of 1,600 square miles out of the 3,794 square miles, 15,060–73. He has no facts to justify his assumption that the geological conditions of the Upper Thames Valley are the same as of the lower. It was merely to show that there was only half the rain allotted to the Thames below Teddington that came from above, 15,074–6. He does not know, nor do geologists know, how much of the water absorbed by the swallow-holes reappears upon a lower level of the same stream, or upon a level adjacent to that. The quantities which reappear in the Mole and the Stour are not at all equal to the quantities which disappear, 15,077–82. He did not know when he called attention to the discrepancies between Mr. Mansergh's and Mr. B. Latham's figures (*see Q.* 13,766 *et seq.*) that Mr. Mansergh had taken Sir Joseph Bazalgette's figures, while Mr. B. Latham made an independent calculation, 15,083–6. With regard to the statement that the water

MR. HENRY LAW—*continued.*

DISTRIBUTION OF THE SEWAGE IN THE RIVER BY THE VARIOUS MOTIONS OF THE WATER—*continued.*

at St. Paul's Pier contained 12 per cent. of sea-water, and that the Lambeth Waterworks used to draw their supply of water from that locality, they took it as far as they were able on the ebb and not on the flood tide. He is unable to say off hand what proportion of sea-water in pure water is necessary to make it undrinkable. It is the sulphate of soda rather than the chlorine which would make it nauseous. He says that the water was not mixed with other water before being delivered to the houses. He has made no experiments to ascertain how little sea-water he could taste, and knows no more on the subject than anyone present, 15,095–113.

POPULATION TO BE PROVIDED FOR.—He hands in Table No. 1, which gives the population of the metropolis in 1881, and the number of people draining into the three main sewers on the north and south sides of the Thames respectively. Tables 2 and 3 give the population draining into the same sewers for each of the districts, and Table 4 gives the population for each of the districts, the amount of sewage intercepted during the 24 hours, and the time occupied in flowing from the point of interception to the outfall, 13,650. On Plan No. 29, there are 80 districts into which he has divided London, and of these 29 districts have been steadily decreasing in population for the last two censuses, and he has shaded or cross-hatched those districts. The diminution occurs in the number of people who sleep in those districts, and he points out that the centre of London will continue to decrease, while the future increase of London will be round the margin or outskirts of London. Consequently the additional sewage which has to be brought in will be brought in at hours when the existing sewage is not running at its maximum, and that is an important point, when considering the size to be given to the sewers. The principles upon which the drainage of a city of 117 square miles is laid out are very different indeed from those of a country town, 13,693–5, 13,700–3. He will supply the populations of the districts which are decreasing, 13,701–2. He does not think the sewage in the centre of London has diminished during the day, but as the water from baths taken in the morning forms the largest element of the supply of water to the sewers, he feels confident there must be a diminution of sewage, though he does not wish to suggest that the diminution is anything like the ratio of decrease in population, 13,703–8, 15,026–32. Mr. Latham stated that the increase of London was going on as it had done for some considerable time before, and he wishes to show that not only is that ratio not going on so rapidly as it did, that it is what is called a decremental rate of increase; but also that as that increase takes place round the margin of London, it does not affect the sewers at the time when the maximum flow takes place from the centre of London itself; there would be a more gradual flow from the sewers, and they would be filled at times when now they are not filled, 13,709–10.

CAPACITY OF THE MAIN DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT: INFLUENCE OF THIS ON THE STORM DISCHARGES. — He has very carefully considered the evidence of Mr. Baldwin Latham, the general tenour of which was that "the increase of "London had outgrown the proportions of the drainage "system, and that, in consequence, whenever rain fell, it "became inevitable that that rain would be discharged "at one point or another by the storm overflows." In order to determine how far that was the case, he hands in a plan (*see Diagram No. 22, Appendix N.*), which shows by the heavy dotted line the district of the Metropolitan Board of Works, the coloured portions representing the area drained, and the parts left white show the undrained area, 13,645–8. The districts drained by the respective sewers are divided and numbered, and the population is divided accordingly. Mr. Latham took the population of "Registration London" as being more or less identical with drained London, which contained about 3,814,571 persons on both sides of the Thames, whereas he has taken Metropolitan London, which contains 3,832,441 persons. The district drained contains 3,880,102 persons, and the population of North Woolwich is included in the numbers on the south side of the Thames. He hands in Table No. 1, which gives the population of the metropolis and the number of people draining into each of the three main sewers, north and south. Tables 2 and 3, which he hands in, give the population draining into middle, high, and low-level sewers respectively for

MR. HENRY LAW—*continued.*

CAPACITY OF THE MAIN DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

each of the districts, and therefore affords data for arriving at the quantity of sewage. Table 4 gives the population of each of those districts, and the quantity of sewage which would be given off by each of those districts, 13,648–50, 14,919–30. Table 4 also gives the time occupied by the sewage in flowing from the point of interception to the main outfall, 13,650. If the sewers were trebled in size there would still be times when the storm discharges would overflow, 13,651–2. In order to determine the hour at which the maximum flow from each branch sewer will come down into the intercepting sewer, he has adopted the gaugings taken by Mr. John Taylor for the referees to the metropolitan drainage scheme, and which appear in a table in the Report made on that scheme in 1857. He has prepared a diagram from that Table, which shows that the minimum flow of sewage is at 4 a.m., the maximum flow is at 10 a.m., when it falls until 3 p.m. It then rises and again falls down towards midnight. On this basis he prepared Table 4, and he now hands in the diagram (*see No. 23, Appendix A. O.*) The same sewers are in existence now as they were in 1857, 13,652–3, 14,931–51. In diagram 24 (*Appendix A. P.*), the vertical height between the line A. A. and the line B. B., is equal to the total discharging capacity of the outfall sewer at Barking, viz., 34,764 cubic feet per minute, and the part coloured red on the diagram shows at each hour how much of that discharging capacity would really be occupied in carrying away the sewage at that particular hour; and it will be seen that the maximum flow is at half-past 2, and that it amounts to 15,000 cubic feet per minute in dry weather, without rain, 13,653, 14,952–61. Diagram No. 33 (*Appendix A. Q.*), gives a section of the northern high, middle, and low-level sewers, showing the height to which they would be filled by the maximum flow of sewage at the present time, or dry weather flow. The maximum discharging capacity of the middle, and low-level sewers is 31,144 cubic feet, whereas the total discharging capacity at the time of the maximum flow is 14,358 cubic feet per minute, or less than half the quantity they are capable of discharging, leaving out rainfall, 13,653–7, 15,007–17. He has prepared Table No. 5, which gives the area of Registration London, Metropolitan London, and Drained London, the totals for which are as follows. (*For details see the table itself.*)

| — | Registration London. | Metropolitan London. | Drained London. |
|---|---|---|---|
| | Acres. | Acres. | Acres. |
| On the North | 78,080 | 31,318 | 32,158 |
| On the South | | 43,229 | 32,843 |
| Totals - - | 78,080 | 74,547 | 65,001 |

65,001 acres are equal to 101·56 square miles, 13,658, 14,967. He hands in Tables 6 and 7, showing the areas of the districts drained on each side of the Thames, the density of the population, and the rainfall discharged into the sewers. Where the population reached 80 to the acre, or exceeded that number, he has taken the whole of the rainfall as going into the sewers, and where the population is less than 80 to the acre, he has taken only half the amount as going in, because in a sparsely populated district it falls on the ground and is absorbed. If the population is dense it falls on the roofs or paved streets, and so finds its way into the sewers, 13,658–60, 14,967–75, 15,000–3. He has assumed that, if rain falls at any spot, for instance at Hampstead, the time it would take to traverse the local sewers before it reaches the great sewer would be 180 feet to a minute, which is, he thinks, a fair and proper velocity to give, and the diagram No. 25, which he hands in (*Appendix A. R.*), shows the time the sewage occupies in traversing the sewer before it reaches Barking, assuming the sewer to be running half full. In that diagram he has assumed that the rain commences to fall at the same time all over London, and that it falls continuously at the rate of a quarter of an inch every 24 hours without cessation for any period you please. It will then be 2½ hours before the first rain, which will be that of Bow, reaches Barking,

Mr. HENRY LAW—*continued.*

Capacity of the Main Drainage System as compared with the Demands upon it: Influence of this on the Storm Discharges—*continued.*

because the outfall sewers are not sewers of reception but of conveyance only; they receive nothing after Abbey Mills. The diagram shows the successive increments of rain in the sewer until it has received its full quantity, which would be delivered for ever if the rain continued at that rate. The figures at the bottom are intervals of time before any given quantity will arrive. If the maximum rainfall be applied to the maximum of sewage, it will be seen that a discharging capacity of 6,000 cubic feet per minute is left in the sewers, which if a very different state of things to that alleged by Mr. Latham. He has made this diagram in duplicate so that the scale of the diagram (in blue) may be applied to the scale of the diagram (in red), 13,661–7, 14,976–82. A velocity of 120 feet is a self-cleansing velocity, and is considered a very good velocity. 180 feet is a high velocity, 15,197–9. If it rained with a steady rain for a week at the rate of a quarter of an inch per diem, the quantity of rain coming off the ground would amount to 14,000 cubic feet per minute, and there would in such an extreme case be an equable flow throughout, 13,668–70. The sewers are capable of carrying off this quantity of continuous rain, leaving a surplus discharging capacity of between 5,000 and 6,000 cubic feet a minute, 13,671–4. The flow of the sewage is remarkably uniform until 9 at night, owing to the time sewage takes to reach Barking from a distance. It takes 9½ hours to flow from Chiswick to Barking. The pink diagram shows how uniform is the flow of the sewage. Mr. Latham stated in his evidence, that whenever it rained the storm overflows came into action at some part or other of the river, and he deemed it right to investigate fully such an important statement. He is glad to find that this statement has been corrected, 13,675–8, 13,685–6, 15,004–6. He has also investigated Dr. Frankland's statement, that, however slight the shower, four-fifths falls into the sewers, leaving one-fifth for evaporation. He finds Dr. Frankland has calculated his quantities on very imperfect data, 13 671–84, 14,996–15,003. There is no doubt that rain falls at times in excess of a quarter of an inch in 24 hours, but it must be borne in mind that there is a very large area unoccupied in the sewers, even when the maximum flow of sewage is taking place. The vacant space in the high level sewer (along its whole length), is 1,362,350 cubic feet; in the middle level sewer it is 1,115,290 cubic feet; and in the low level sewer it is 1,675,623 cubic feet; and, in the three outfall sewers, 2,715,180 cubic feet, giving in all a total of 6,868,443 cubic feet, which is equal to eight hours' rainfall, and this must be filled by rain before the sewers would become sufficiently filled to overflow by the storm overflows, 13,685–8. Mr. Latham stated that the joint discharging capacity of the three sewers was in excess of that of the outfall sewer, but it is not so, because the sewers were constructed to carry off a proportionate quantity of sewage at different times. The time of greatest discharge is different for each sewer. If the sewers had to discharge all their maximum at once 1,680 six-inch sewers would be required to carry off the sewage of the whole of London, which, estimated at 40 cubic feet per minute from 490,000 houses, gives a total of 19,600,000 cubic feet per minute, and this is absurd. Before the three sewers are united, storm overflows are provided to relieve the sewers because it was practically impossible to design the sewers so that they might be competent to deal with the whole of the rainfall which might be delivered to them under extraordinary circumstances; but that is vastly different to saying that whenever rain falls the storm overflows come into play, 13,689–91. He has not come to any conclusion as to the number of times the storm overflows should come into operation, but the result of his calculation bears out the reasonableness of the return which has been furnished from observation. The figures which he has given of the capacity of the sewers to be filled up by sudden falls of rain apply simply to the intercepting sewers, and a very large number of hours would elapse before an overflow occurred, even after heavy rain. He quotes an extract from the Report of Mr. John Taylor to the Referees as the result of his observations of the gaugings during heavy storms of rain, from which it appears that no definite quantity can be pronounced to flow off any given district with a given fall as so much depends on the previous state of the ground, on the quantity of rain falling in a given time, and the duration

Mr. HENRY LAW—*continued.*

Capacity of the Main Drainage System as compared with the Demands upon it; Influence of this on the Storm Discharges—*continued.*

of the fall. In a town district the quantity of rain running off in six hours varies from 10 to 60 per cent. of the quantities fallen; while in a suburban district it varies from 0 to 30 or 40 per cent. in 24 hours after the rain has fallen. In one case after a rainfall of one inch in 1¼ hours, 65 per cent. ran off within 15 hours of the fall, viz.:—46 per cent. in three-quarters of an hour after the rain ceased; 14 per cent. more in the next 6¾ hours; and 5 per cent. more in the next 7½ hours. In his calculations he admits of 70 per cent. running off, which is in excess of that which really happens. The result is this, that while the discharging capacity of the sewer (when it reaches the lip of the sewer) is 34,764 cubic feet per minute, the maximum of the sewage will be 15,070, and the rainfall 14,242, leaving a surplus of 5,452 as the carrying capacity of the sewers with the maximum sewage and rainfall, which would be available for increase of population, 13,692–4. For a month past, in consequence of some experiment being made, one of the outfall sewers has been temporarily diverted from its use, the whole of the sewage being turned into the other two sewers, and the maximum time and the quantity of sewage are singularly confirmatory of the conclusion he has drawn here from these figures. The result is that the two sewers have taken the whole sewage, one being filled to a depth of 3 feet 9 inches, and the other had 4 feet of sewage in it. After a very heavy fall of rain only six to seven inches extra were gauged, 13,710–14. The storm overflow was not at work because the sewers were not full. Before an overflow can take place the carrying capacity of the sewers must be exhausted, and the sewers must be filled. Then they overflow, as the rain or sewage would be headed back. If the sewers were of such a capacity that a shower of rain would fill them more quickly than they could discharge themselves, there would be an overflow, but in such a hypothetical case the sewers must absorb an enormous quantity of water before they can be filled, and it must be borne in mind that the contents of the sewers are not stagnant water, but that they flow with great speed, increasing in velocity as the sewer gets fuller, 13,714–9. He has ascertained that the quantity of rain which fell last Saturday (26th May 1883) between 9 a.m. and 12.15 p.m. was $\frac{17}{100}$ths of an inch, and between 4.30 p.m. and 6 p.m. $\frac{15}{100}$ths, making a total of one-third of an inch in 9½ hours, and although only two sewers were at work no overflow occurred at any part of the system. A drizzling rain fell during the interval from 12.15 p.m. and 4.30 p.m., and the system which was provided for a quarter of an inch in 24 hours with three sewers was sufficient to take one-third of an inch of rain when only two sewers were at work during the maximum flow of sewage, which occurred at 2.30 p.m., without any overflow at all, 13,847–8. He disputes Dr. Frankland's statement that $\frac{1}{100}$th part of an inch of rain in 24 hours would increase the flow of sewage at Barking by 14,000,000 gallons daily. Not a particle could ever reach the sewers because it would be dissipated by evaporation, 13,889–90, 15,126–8. It was not intended by the Metropolitan Board of Works to make another main sewer in the north to prevent the overflow during storms, but they are building a new sewer to carry off the storm waters. The works the Board has in contemplation, but which await the decision of this Commission before carrying them out, are the enlargement of the reservoirs at Barking and Crossness, so as to avoid the necessity of letting the sewage pass out during the flood or continuing so long during the ebb, 13,974. He is acquainted with Sir J. Bazalgette's evidence, and knows he stated that the rainfall at Greenwich and Kew did not correspond at all, but he has not examined Mr. Symon's tables with the view to form any opinion as to the coincidence of rain at those places. The tables of Greenwich rainfall were not prepared by him nor under his superintendence, 14,870–80. He differs from Mr. B. Latham in thinking that the population and the sewage requirements of London have outgrown the drainage system, 14,881–2. He attributes the necessity for the increase of large storm overflows to the fact that owing to the greater surfaces which contribute the rain to the sewers a larger quantity of rain is carried away through the sewers. New sewers to relieve existing sewers have been or are being constructed at Vauxhall, Wapping, Deptford, and the Fleet Valley; he will, however, obtain a list of all the storm overflows which have been provided within the last ten years, 14,880–

## Mr. HENRY LAW—*continued.*

CAPACITY OF THE MAIN DRAINAGE SYSTEM AS COMPARED WITH THE DEMANDS UPON IT; INFLUENCE OF THIS ON THE STORM DISCHARGES—*continued.*

903. The increase in the population, together with the increase in amount of paved streets, which brings more rain into the sewers, brings with it an increase in the sewage as well, 14,904–10. The population has increased in the Hackney Valley, Effra Valley, and Quaggy districts (*see Diagram No.* 22), but that plan does not show in which districts provision was made for a quarter and an eighth of an inch of rain respectively; he is not aware that in those districts where an eighth of an inch was provided for, a large increase in population and building has taken place, 14,911–8. He still asserts that allowing for the increase in the population, the main sewers are adequate to carry off the whole of the sewage. They are, in fact, capable of carrying off more than double the quantity they were originally designed to take, 14,919–30. He used Mr. John Taylor's gaugings to ascertain the hourly flow, not the quantity, of dry weather sewage; and the inaccuracies in those gaugings which have been pointed out by Sir J. Bazalgette and others, do not impugn the use he has made of the gaugings, because he made use of the dry weather gaugings only, 14,931–51. The high and the middle level sewers flow by gravitation; it is only the contents of the low level sewer that are pumped at Abbey Mills. The maximum flow of the high level sewer is 1,800 cubic feet a minute, that of the middle level sewer 7,788 cubic feet a minute, and the low level sewer is 6,570 cubic feet a minute. Out of the total amount of 15,000 cubic feet a minute, about 6,000 cubic feet are pumped, 14,952–66. He is not aware that the Metropolitan Board of Works gauged the sewers in 1865 to ascertain the velocity of the flow through them. No trace exists in the Board's offices of any such gauging, and the books produced, which are signed by a man named Wa er, he believes to be gaugings taken by the Essex Recl . ation Company; they have no connection with the M tropolitan Board of Works, 14,983–8. Diagram No. 25 only shows the increase in the quantity of rain discharged from the sewers up to ten hours. After that it runs as a constant quantity at the given rate, 14,989–90. He repeats that the carrying capacity of the sewers is more than sufficient to carry off a quarter of an inch of rain in 24 hours. and when they are carrying off that quantity with the maximum flow of sewage, they have a surplus capacity of 5,452 cubic feet per minute. When the rain exceeds that surplus then the sewers overflow, 14,991–5. He is not aware that Mr. B. Latham referred to rain which was over $\frac{1}{100}$th of an inch in an hour, when he referred to the overflow at some point or another. Mr. Latham made no such qualification about it, 15,004–6. The total discharging capacity of the high level sewer is 16,620 cubic feet a minute, the middle level sewer is also 16,620 cubic feet, and the low level sewer is 14,524 cubic feet a minute, making a total discharging capacity at Abbey Mills of 47,464 cubic feet a minute. They are capable of discharging this quantity for a quarter of a mile. From Abbey Mills the three sewers cease to be intercepting sewers, and become sewers of discharge. Their united discharging capacity from that point is 34,764 cubic feet a minute, 15,007–25. The sewage at Crossness does not fall into the river, but is conducted by pipes to the bed of the river, whence it issues below low-water mark by means of the pressure of the sewage in the reservoir. The outlet never gets covered with gravel or anything of that kind, and it is never silted up. The outlet is always covered by water. At Barking the sewage outfall is covered at high water, but is visible at low-water, and the sewage can be seen as it is discharged. The beach at Barking is very short, and although the Crossness system of discharging could be carried out there, he is doubtful, when the reservoirs are enlarged, whether it would be an improvement. Under present circumstances the Crossness system is preferable to that at Barking (*see* remarks after Q. 14,571, evidence of 38th day). Referring to his answer to Q. 13,847 when he stated that none of the storm overflows were at work on a certain day when rain fell, he is not aware that the Blackfriars sewer was overflowing the whole day, but he will inquire into it, 15,091–4. The considerable number of storm overflows, which have been constructed of late years, must not be taken as showing that the drainage system is not sufficient to carry off the sewage, because the natural watercourses having been filled up, it has been necessary to substitute artificial watercourses in the shape of overflows, or, more properly, relief sewers, for them, 15,200–2.

## Mr. JOHN WILLIAM TRIPE, M.D., M.R.C.P. Edin.

President of the Society of Medical Officers of Health, and Medical Officer of Health for the Hackney District.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—For some time past he has been investigating what influence the river has on the health of the riverine districts, and he selected as the most suitable places for the purposes of his inquiry, Greenhithe, Erith, Woolwich, Greenwich, and Rotherhithe. These sites he visited, and went very carefully over the whole of the districts, noting the class of houses, the complexions and general appearance of the people, and the condition of the children especially. The districts and streets which he visited are set out upon the maps which he hands in. (*See Appendices, B. R.* 1, 2, 3, *and* 4.), 13,977–80. He also obtained the number of deaths from the seven zymotic diseases, marking on the maps the exact spots where they occurred in streets running at right angles to, or at an acute angle with, the river, and in the case of those parallel with the river they are simply marked, as it is not of so much importance, 13,980. He took the years 1878, 1879, 1880, and 1881, as they afforded a sufficiently long period for his purpose, and included hot and cold weather, as well as in some of the years an epidemic of scarlet and typhoid fevers, and to a certain extent diphtheria. From the Registrar-General's returns of deaths he made out his spot maps, which he thinks are of greater value than percentages of deaths, because it will be seen that the greater part of the deaths have occurred away from the river. Another important point is that, as a rule, in the small courts and places near the river, where the people are poorest, and there is most crowding, the deaths are fewer in number than in the streets farther away, 13,981–2, 14,042, 14,189–93. He has included also the deaths in the Greenwich Infirmary, and in the Deptford and Stockwell Fever Hospitals, in order to make the record as accurate as possible. The percentage of deaths from zymotic diseases as compared with deaths from all causes in the four years 1878–81, is shown in Table I., 13,983–4, 14,167–73. The seven zymotic diseases are small-pox, measles, scarlet-fever, diphtheria, whooping-cough, typhoid, and diarrhœa. In addition to those, he has separated typhus from typhoid; otherwise an erroneous impression would have been created, as in Rotherhithe there was a severe outbreak of typhus which resulted in several deaths in private houses and in the hospitals, 13,985. On the maps the red spots indicate scarlet fever, yellow indicates typhoid, blue, diphtheria, and black, diarrhœa, 13,986. He has been unable to prepare a spot map for Greenhithe, as there were no data of the zymotic diseases for that place at the Registrar-General's office, 13,982–7. In Erith, during the four years there were only ten deaths altogether from zymotic diseases. It is a very healthy place, 13,987–9, 14,104. Zymotic diseases are comparatively rare on the margin of the river at Erith, (that is to say, within a quarter of a mile from the river,) more deaths occurring from those causes in the area further away, 13,990–2. At Woolwich in the four years there were 10 deaths from zymotic diseases near the river, and that district is occupied by very low classes of people living in very poor habitations, and they are exceedingly liable to suffer from these diseases. The deaths in the district further away from the river are much greater, although the class of inhabitants is better, and the population is not so dense. The part of Woolwich he has tabulated ought *a priori* to be very unhealthy, but, as a matter of fact, in that part of Woolwich there is proportionately less zymotic disease than there is in all London, 13,993–7, 14,134–7. Table 2 gives the average annual death-rates from zymotic diseases for two decennial periods, viz., 1856–1865, and 1871–1880. The death-rates in the first period are corrected for excessive death-rates from zymotic diseases all over London during that period, 13,998. Taking Greenwich and Woolwich together from 1856 to 1865, before the sewage was taken there, the zymotic death-rate was 3·95 per 1,000, but from 1871 to 1880, when the sewage is taken there, the zymotic death-rate is positively less, viz., 3·47 per 1,000. So, when the sewage was taken away from Bermondsey, in St. Olave's there was an increase in the number of deaths from zymotic diseases, and when the sewage was taken down to certain places the death-rate decreases in those places, 13,999–14,000, 14,155–63. Greenwich has always had an excess of diarrhœa, but he cannot explain the reason why; if the severe

MR. JOHN WILLIAM TRIPE—*continued.*

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS—*continued.*

epidemic of 1866 be deducted from the total zymotic death-rate of 18·18 per 100, it would be reduced to about 14. The parts which are densest in population appear to suffer least, and possibly it is due to the fact that the air from the river blows out the bad air from the houses, and there is nothing injurious carried from the river into the houses, 14,001–2, 14,021–4, 14,146. The diseases which are most likely to arise from the emanations from the river are not found in the vicinity of the river, 14,003–4. There are very few warehouses on the river bank in proportion to the number of dwellings, as compared with the area further in, 14,005–9. Of the solitary death from diphtheria in Rotherhithe Street, it was really a case of diphtheria peritonitis, which can hardly be considered to be a death from diphtheria, so that if this be eliminated from the tables, diphtheria in the neighbourhood of that part of the river disappears, 14,010–11, 14,018. As regards hospitals he only obtained statistics as to deaths, but none as to recoveries, 14,012–13. He thinks the death-rate is a fair criterion of the ratio of disease, he knows of no more reliable method, 14,014–7. The Greenwich area is more limited than it would have been if he had decided on the spot map system at first. He was unable to obtain the census from Somerset House, so that the only census he had was that of the training ships; and therefore he adopted the per-centage of zymotic diseases to total deaths. Nearly the whole of the river frontage at Greenwich is occupied by wharves and quays, and in the four years there has been only one death from scarlet-fever near the river, and that was in Bennett Street. There was one in Newcastle Street, an eighth of a mile from the river, but all the other cases were in the streets about the middle of the area or further away, 14,018, 14,103–15, 14,116. Except the block of houses between Paradise Street and Rotherhithe Street, the river frontage at Rotherhithe is quite blank; the neighbourhood is very poor, and much crowded. In that small bit of the district there have been a large number of deaths from scarlet-fever, and one from diphtheria, but none from diarrhœa or typhoid, 14,018. In Princess Street, which runs at right angles to the river, there were two deaths from diphtheria, one from diarrhœa, two from scarlet-fever, and two from typhoid fever. It is the only instance of that kind of thing occurring, and these cases are distributed partly near the river and partly away from it. There is a similar kind of aggregation of disease in Adam Street, Albion Street, and Risdon Street, but, as the map shows, along the bank and along Rotherhithe Street, there is nothing of the kind. Elephant Lane is a much poorer street than Princes Street, but it was free from diarrhœa, 14019–20. From the Supplement to the 35th Report of the Registrar-General he obtained some figures which enabled him to compare the deaths from zymotic diseases with the deaths from all causes, which proved that he was right in adopting that basis. The results he obtained are as follows:—

TABLE showing the NUMBER of DEATHS in ENGLAND and LIVERPOOL from all CAUSES and from ZYMOTIC DISEASES to 100 DEATHS in the HEALTHY DISTRICTS from 1861–1870.

| ——— | Healthy Districts. | England. | Liverpool. |
|---|---|---|---|
| Deaths at all ages and from all causes | 100 | 138 | 229 |
| Deaths at all ages from seven chief zymotic diseases | 100 | 140 | 232 |

Applying that to the selected districts for the four years 1878 to 1881, the zymotic death-rate in all London was 16·23 per 100 deaths from all causes, whilst in the riverine selected areas it was—

| | |
|---|---|
| In Greenhithe | 12·85 |
| In Erith | 13·26 |
| In Woolwich | 11·14 |
| In Greenwich | 18·88 |
| In Rotherhithe | 23·67 |

MR. JOHN WILLIAM TRIPE—*continued.*

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS—*continued.*

The excess in Greenwich arose from measles and diarrhœa, which, as shown in Table 1 were enormously high as compared with the returns for the other districts. If this excess were reduced to an average, allowing for an increase in scarlet fever, which was diminished by the measles, the average zymotic death-rate in Greenwich it may fairly be assumed would be about 14·5 or 15 per cent. of the total deaths as compared with the London death-rate of 16·23, 14,025–8, 14,140–1. The singular coincidence as regards the large number of deaths from measles and diarrhœa at Greenwich does not suggest that similar causes may have produced them, because diarrhœa has not been so prevalent to the same extent during any period except those four years, 14,029. Measles and whooping-cough are in no way connected with sewage, and he has therefore struck them out of his spot map, 14,030. He accounts for the deaths from zymotic diseases in Rotherhithe being higher than in any other parts of London, chiefly by the character of the population and the number of children, and mentions the case of Liverpool as a proof of his statement, where there is a very large number of children, and where the death-rate of children under five years of age from zymotic diseases as compared with deaths from all causes amongst children under five is 343 to 262, which is double the number in all England, 14,031–4, 14,140–1. He agrees with Dr. Corfield in thinking that the high death-rate from zymotic diseases in St. Olave's, Southwark, was not caused by the river, and the spot map fairly corroborates this, but not to the same extent in other districts, 14,035–7. Dr. Corfield's tables are not reliable to a certain extent for comparison, because the deaths which occurred in hospitals from fever and small-pox are not distributed to the parishes from which they were brought, and also because *all* fevers were grouped together under one head, instead of being properly classified, 14,037–9, 14,174–82. He does not believe that the river or the drains by themselves, irrespective of germs, ever caused typhoid fever, small-pox, scarlet fever, or whooping cough; but he believes that insanitary conditions render persons more susceptible to taking the disease, and that they are likely to prove more intense by debility and a bad state of the blood. Dr. Corfield also looked on scarlet fever as being more likely to be influenced by the river, while the spot map shows that there is very little scarlet fever near the river, except in Rotherhithe. Table 2 is a comparison between his statistics and Dr. Corfield's, 14,039–40, 14,042, 14,174–84. He selected zymotic diseases as a test for sewage contamination, because they are considered to be the diseases which chiefly arise from or are affected by sewer emanations or emanations of that kind. Throat diseases are often caused or made much worse by sewer emanations, 14,043–5. Speaking generally, Greenwich and Woolwich are healthy, Dartford and Gravesend are very healthy, and Hoo is singularly healthy, the death-rate at this latter place being only about 14, and yet the zymotic death-rate was higher in the years 1856 to 1865, when the sewage was not there, than in 1871 to 1880, when it was there, 14,043, 14,046–7. He cannot suppose that the river emanations were blown over the houses on to the land beyond, except by very high winds. Except diphtheria, he knows of no other zymotic disease which is carried any distance by the wind. Small-pox has been stated to be carried by the wind, but it is entirely contrary to his experience. Supposing that it was possible for the emanations to be so carried, the effect would diminish as the square of the distance increases, inasmuch as the emanation, whatever it was, would become mixed with such a large quantity of air in being carried away, and the air would also oxidise it. The districts are mostly flat, except at Gravesend and Erith, where there is a little rising ground, 14,048–51. He hands in Table No. 5, which gives the annual average deaths from zymotic diseases from 1871 to 1880 for the sub-district of St. Olave's, Southwark, St. John, Horsleydown, St. James, Bermondsey, and Rotherhithe, and also for the sub-district of Leather Market and St. Mary, 14,040. The density of population in the latter sub-district is greater by 50 per cent. than the population in the former, and to a certain extent may affect the result obtained of the total zymotic death-rate, 14,052–3. He does not believe that the outbreaks of typhoid fever on board the training ships, on which Dr. Collingridge has given evidence, were in any way attributable to the river, for

## Mr. JOHN WILLIAM TRIPE—*continued.*

### Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

the sick were removed from the ships, and those who remained were perfectly healthy, although they were, so to speak, in the infected area. He thinks it possible that polluted water got by some means, possibly leakage, into the water supplied to the ships, which in itself is sufficient to produce typhoid fever. Another point mentioned by Dr. Collingridge, that when yachting he suffered from diarrhœa and sickness caused by the state of the river, he suggests that irregularity in taking meals and knocking about produced diarrhœa and dyspepsia, 14,054–62. The total population of the five training ships is 1,506, and the average death-rate for those on board the ships is about 4·2 per million, as against 6·72 per million for all England between the ages of 10 and 20. The average rate for all England is about 20 per million. He considers the continuance of the disease on board the ships was due to overcrowding, to the infectious nature of the disease, and to insufficient ventilation, 14,063–73. The captains have very wisely discontinued the use of the river water for any purpose whatever, 14,073, 14,185–8. If the water was drunk the boys would undoubtedly make themselves ill, 14,073–5. None of the medical officers to the Customs or police in their reports attribute any ailment of the men to any alleged injurious effect of the river, with the exception of Dr. Browning, whose evidence before this Commission is not corroborated by his reports to the surgeon-in-chief to the Thames Police. The chief causes of death reported by these doctors are pneumonia, rheumatism, and so on; zymotic and febrile disease, they say, being proportionately small, 14,076–82. On the foreshore at Erith, between the National Schools and the Lower Ballast Wharf, there are not many houses, with the exception of two or three rows of houses it is mostly open country. Between the ballast wharf and the pier the foreshore is mostly occupied by wharves, but there are certain gaps. The deaths recorded in the maps occur in the more populated parts of Erith and in the poorer neighbourhoods, 14,087–102. In Greenwich there were very few cases of zymotic disease upon the river side of Chester Street, although some of those streets comprise a very low class of houses. Then comes some waste land and Greenwich Park, and all that part of Greenwich from the Woolwich Road down to the wharves on the river is densely populated, and although it might be expected that disease would be rife there, no disease has been found. The ratio of the population between Chester Street and the river, and Chester Street and the district beyond, is in the proportion of two to three, 14,105–16, 14,194–7. At Woolwich the river frontage is covered almost entirely with wharves, workshops, gasworks, &c., but in that district very little is more than a quarter of a mile from the river, but the map shows that most of the disease is situated at the back rather than at the front near the river. The ratio of the population between High Street and the river, compared with between High Street and the back, is as one to two. He went over the district very carefully in order to come to a fair conclusion, 14,117–32, 14,194–7. With density of population scarlet fever has a tendency to increase, 14,133. The death-rate from scarlet fever in Greenwich and Woolwich for the 10 years was 1·03, and he would expect that the Woolwich rate would be far below London, but between 1871 and 1880 the rates were ·61 and ·60, 14,134–6. The density of population for Woolwich is 11·8, and for London is 46·9. The densest places, as a rule, are the worst, 14,137–40. The Liffey is a very narrow stream at Dublin, and is filthier than the Thames, and the two rivers should not be compared together. All round Dublin zymotic diseases are very rife indeed, and the rate of mortality is exceedingly high. Owing to the height of the river walls, there are some parts where the sewage in the Liffey within the city is not oxygenated at all, 14,147–54. The state of health of the lower districts, even after the sewage had been taken down, depends upon the seasons, and he does not attach so much importance to the death-rate statistics of the Registrar-General as he does to his spot maps. After them, his Table I. he regards as next in value. His tables and Dr. Corfield's are of about equal value, 14,164–5. Speaking generally, along the margin of the river the houses and rooms are small, and there is much overcrowding in consequence, but upon the whole the margin of the river enjoys a singular immunity from zymotic disease, 14,194–7.

## Mr. JOHN HOLMES GROVES.

Licensed Waterman, temporarily employed by the Metropolitan Board of Works.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls. — For the purposes of this inquiry he made some experiments with fish to test the state of the water in the river, 14,328–31. He got some eels from a Dutch vessel lying off Billingsgate, and put them in a box, which he lowered into the water at Erith, off the "Castalia." They remained there for seven weeks and then died. On another occasion he put some eels into a box at Greenwich, which was submerged to a depth of six feet. He then let it float down the river as far as Erith and return on the flood past both the outfalls. If anything, there appeared to be an improvement in the eels after their voyage. He then moored the box at Greenwich, and they lived for two months, when the box was stolen or broken up, 14,364–7, 14,377–97.

Distribution of the Sewage in the River by the various Motions in the Water.—In October 1882 he was employed by Messrs. Law and Chatterton, together with a man named Gadsdon, to take soundings of the river. On the 16th of that month he was on the north bank of the river in Erith Roads laying out sections, when he saw a boat belonging to the Corporation of London apparently attached to a float, the float being ahead of the boat. The tide was flowing up, and there was a strong east-south-east wind blowing at the time. It is his opinion that if the boat was not attached to the float the velocity of the wind would have taken the boat right away from the float. The boat and the float remained in the same relative position to each other, viz., about two feet apart, while they remained in sight, which lasted for a quarter of an hour. He could not see that the float tilted at all, nor was there any drag attached to the boat to retard its progress. When he saw them they were to the south of mid-channel, 14,198, 14,232, 14,374–6. The men were in the bottom of the boat, out of sight, and had no oars out, 14,236–9. On the morning of the 19th October, at 6.15 a.m., Gadsdon and he were on the river in a boat going down to Erith on the ebb tide, the wind being south-east. About 20 yards from him he saw a Corporation boat to which a float was attached by a small line. The wind stopped the boat's progress, and the men in that boat were Mears and Whiting. The float was ahead of the boat, 14,240–56. His memoranda, which he produces, only contain notes of his own work, 14,258–64. On the 29th of October, at 5.30 a.m., he was on Greenwich Pier, and saw a float attached to a boat in which were two men, Tanner and Long. They rowed to the pier, made the boat fast, and remained on shore for 25 minutes. When they came back they towed the float into mid-stream and then cast it off. He knew this was wrong and reported it and the other cases to Mr. Chatterton in November, 14,265–77. On the 30th of October he was in his boat with four other men going home, when in Tripcock Reach to the south of mid-channel he came upon a boat very close in shore, both boat and float being aground. The latter was in an almost recumbent position. The tide was entirely slack, and two men in the boat, whom he recognised, were covered with a sail, and they were both asleep, 14,278–92. He has been employed by the Metropolitan Board of Works, off and on, for 19 years, and last October he was engaged first of all to watch the float operations, and to report anything which he saw that was wrong. He does not remember on what day the floats were first put into the water, but he thinks it was in September. His notes (in a book produced) relate to those experiments, and also to some experiments he made with fish to test the water for the purposes of this Inquiry, 14,293–331. He made his reports once a week to Mr. Chatterton. The floats were numbered, and he read the figure 4 on the float he saw on the 16th October. His notes do not follow each other consecutively. They were entered day by day, but in various parts of the book in an irregular manner. Whenever anything happened he invariably entered it in his book on the same day, 14,332–57, 14,374–6. On the 16th, 19th, and 30th October, the floats he saw were big ones; on the 29th October it was a small, or bucket, float. He is unable to give the number of the float in charge of Mears and Whiting, or of the one in charge of the men who were asleep. He knows it was a Corporation float, because he knew the men, 14,358–63, 14,368–73. He believes the float numbered 4 which he saw on his way home was the float which he saw attached to the boat on the morning of the 16th October, but he cannot say for certain, 14,374–6.

## Mr. CONRAD HENRY WALTER GRUNDTVIG.

Student at the Institution of Civil Engineers, and Pupil of Messrs. Law and Chatterton.

Distribution of the Sewage in the River by the various Motions of the Water.—On the 16th of October 1882, about 1 p.m., he was putting in pegs upon the north shore of the river for the purpose of taking sections, being assisted by Groves and Gadsdon, when he saw a boat passing up the river, in a line with Anchor Bay, stern foremost, and with a float attached to the bow. He identified it as a Corporation boat, both on account of the float, and also by the red flag in the stern. He could not see the number as the flag was lying down. He did not see the line by which the float was attached, but as it was slightly inclined he believed it was fastened to the boat, 14,398–406. On the same day he saw another boat going up the river broadside and whirling about, and the men had to use their oars to keep back the float. They kept together for a quarter of an hour when he lost sight of them as they swept round Coldharbour Point, 14,407–23

## Mr. JAMES EDWARD PETRIE.

Greenwich Waterman.

Distribution of the Sewage in the River by the various Motions of the Water.—On the night of the 15th October he was watching No. 6 float. He began at Bow Creek about 9 o'clock when the tide began to run up. The wind was east-north-east. At Millwall Pier he saw the men in charge of the float had fastened the float to the main or middle thwart of the boat, and it dragged the float along. They went as far as Fulham when the tide returned, and he followed them down to Greenwich. At Battersea Bridge, it being then daylight, he saw the men cast the float off because there was such a current the float might have knocked a hole in the boat. He was close to them all the time. The names of the men were Long and Hampshire, 14,424–44. He made notes at the time of all that occurred, and he produces copies of them. The originals were soaked with the rain which fell during the morning. The float was hurried up with the tide, because the boat was athwart the tide and the wind had great effect upon it. He had to use his sculls to keep his boat back to the float. In coming down the float went much faster than the boat, and he had to scull hard to keep up with it, 14,445–51. He had been watching this float for a fortnight, and was relieved at intervals as the Corporation men were also. They knew they were being watched. He did not enter this on his daily notes, as he would remember it when reported the result of his "drive" to Groves, who reported it to Messrs. Law and Chatterton. He had noticed no previous irregularity, 14,452–73. He was engaged in watching for about a month, but he saw nothing irregular after the 15th October. He reported this case to Groves within 12 hours after he observed it, 14,475–83.

## Mr. ARTHUR JAMES AVENT.

Greenwich Waterman.

Distribution of the Sewage in the River by the various Motions in the Water.—On the 30th October 1882 he was in a boat with Groves and Gadsdon, when he saw a float made fast to a boat, and the men who were in the boat were asleep under a sail. Their names were Taylor and Clements. This was in Tripcock Reach, as he was going home about a quarter-past five in the morning. As they passed the boat they hailed the men in the other boat, who jumped up from under the sail. He saw the line attached to the float, which was tied on to the boat's thwart, and the other two men who were with him could also see the line, 14,484–504.

## Mr. ANDREW WISE, L.R.C.P. Edin.

Physician and Surgeon.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He lives at 207, Burrage Road, Plumstead, and since the opening of the outfalls has attended the people employed by the Metropolitan Board of Works, who live at Crossness. Their health is quite as good as that of people residing elsewhere, 14,505–7, 14,533, 14,558–62. He has been unable to trace any diseases there to the influence of sewage; there is no

## Mr. ANDREW WISE—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

larger proportion of diarrhœa or zymotic disease prevalent there than elsewhere, and there has not been one case of typhoid fever amongst the 50 men employed there. Including children, the population of the place is about 150. Zymotic diseases are no more prevalent at Plumstead than elsewhere, and the influence of the discharge of the sewage into the river upon the health of the neighbourhood is nil, 14,508–16, 14,549–55. He has noticed bad smells in Plumstead, which are due to the factories on the river. Some of the cottages at Crossness are on the banks of the river, but there is no smell of sewage in the cottages themselves, 14,517–20. His opinion as to zymotic diseases is derived from a general impression and from his experience as a medical man in other places. It is not based in any way upon statistics, 14,521–7,14, 531–2. The smells he cannot describe, but they are very unpleasant, and he should say they are not due to sewage. He cannot trace any disease to these smells, 14,528–30. His district begins at Woolwich, and extends to Belvedere from Shooter's Hill. Belvedere is about two miles from the river, and stands on much higher ground than Crossness, 14,533–48. The cottages are situate not more than an eighth of a mile from the point where the sewage is actually discharged. He would recommend a site further away in the future, but from past experience he does not fear any evil results, 14,556–7. He does not attend the Crossness workmen's families in ordinary cases of illness, 14,563–7. In such cases he might be called in, but they have employed other doctors. He would be informed if any illness existed, even though he were not in attendance, 14,568–70. Sometimes several months elapse without his being called to the works, 14,571.

## Mr. JOHN DIXON, M.D., L.R.C.P., M.R.C.S., Lond. L.S.A.

Medical Officer of Health for the Bermondsey District.

Effect upon Health in the neighbourhood of the Main Outfalls.—He has held his present appointment for seven years, and previous to that he was Poor Law Medical Officer for 14 years for the waterside district of Bermondsey, which had an area of 391 acres, and a frontage to the river of half a mile. He has had 25 years' medical experience in Bermondsey, and lives at 133, Jamaica Road, Bermondsey, 14,572–81. There is no evidence in his district of any injurious effects on health from the sewage in the Thames. The riverside population was more dense than in the districts further back a few years ago, but some of the houses have been pulled down and warehouses have been built. Those houses which still remain are smaller and older than they are elsewhere in his district. The inhabitants are very much of the same class, 14,582–5. Typhoid fever has been below the average for several years, and there was only half the proportion of enteric fever which existed in London. For the whole parish there is more than the usual proportion of children, and in St. James's District, which is the riverside district, the proportion is the largest. The effect of this is, that there is more than the fair proportion of deaths from measles and whooping cough, and, in some years, from scarlet fever and infantile diarrhœa, and the zymotic death rate may be higher than that of London, though there is less fever. He has never seen any signs of sewage in Bermondsey or smelt it, 14,586–88. The river frontage always has been principally occupied by warehouses, graving docks, and shipping, but there are poor houses upon the opposite side of the Bermondsey wall within a few feet of the river. All through Rotherbithe there are no private houses by the river side, 14,589. He gives the boundaries of Bermondsey parish, which contains 626 acres, which is the area he referred to in mentioning the average of enteric fever. The length is about a mile and a half, and the breadth is one mile. There were only nine cases of enteric fever in twelve months, 14,590–7, 14,613–14. In the quarter of a square mile abutting on the river there were only two cases of fever, and it was doubtful whether they were enteric fever or not. He did not attend them. There were no cases of typhoid fever at all, 14,598–601. The average death rate for zymotic diseases in the parish of Bermondsey for the ten years from 1871 to 1880 is 4·60. Last year the rate per 1,000 was 4·80 as against 3·49 for London. Whooping cough was 2·03, London 1·20; measles 1·24, London

## Mr. JOHN DIXON—*continued.*

### Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

0·60. The excess from these diseases alone exceeded the excess above the general zymotic rate for London. The enteric fever rate for last year was London 0·25, Bermondsey 0·10, 14,602–12. During the last ten years the health of Bermondsey and his district has considerably improved, and he attributes it to the main drainage in a very large measure, and to the filling up of the tidal ditches which formerly existed, as well as to improvements in the dwellings of the poor, 14,615–16.

## Surgeon-Major CHARLES WILLIAM GRIFFITH, M.R.C.S., L.R.C.P.

Brigade-Surgeon in charge of the Magazine at Purfleet.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has been stationed at Purfleet since November 1880, and his house is about 60 yards from the river. His garden runs down to the river. The hospital is about 35 yards from the river, and the barracks are from 200 to 300 yards distant, 14,617–23, 14,656–7. The river is discoloured at times, but he does not smell the sewage in the river at Purfleet. He has noticed a smell from a blood manure factory, and also from a glue factory at Rainham (Essex), and at or near Erith. Had the smell from the river been perceptible he would have been able to distinguish it. The factory smells are equally prevalent whether the tide is ebbing or flowing when the wind comes from the north-west or west, 14,625–33, 14,642–55. In hot weather he sits with his windows and doors open, and he has never smelt the river unless the local drains are out of order. The shore is composed of shingle and chalk stones; there is very little mud there, 14,637–41. He first noticed these smells early in 1881, and they are worse now because a new factory has been established at Rainham. This factory is close to the river bank, as nearly as possible in a line with the Rainham Railway Station. He knows the smell well; it is either a blood manure, or a glue manufactory. He does not know the exact position of the factory at Erith, but the smell is brought up with a south-west wind, 14,642–55. The river is not so likely to smell when there is a large quantity of land water in it, as it is when there is little or none, 14,671–3. The factory smells are very disagreeable, and having once smelt them they would be remembered. He cannot describe them. He knows very little of Erith, having only landed there occasionally, 14,679–81. He is distinctly of opinion that the smell is not from the river, and he has never smelt it with an easterly wind. The smells are chiefly noticeable in summer, 14,682–4. His men are not allowed to bathe in the river, on account of the strength of the current, and the under currents, which make it excessively dangerous. For these reasons he would not care to bathe in the river, and also the water is not so clean as he could wish it to be, 14,695–6.

Effect upon Health in the Neighbourhood of the Outfalls.—Speaking from the medical records of patients admitted to the hospital since 1876, they contain no cases of disease which can fairly be attributed to the emanations from the river, 14,624. There is no case of typhoid upon record, but one has recently occurred. Diarrhœa is not prevalent in the neighbourhood, and the general health of the troops and employés is very good, 14,634–6. The training ship "Cornwall" is moored about 500 yards below Purfleet on the Essex shore, and about 350 yards from the outfall. Typhoid fever is always more or less prevalent on board, and there is an outbreak now on the ship; but he does not know the number of cases. (The witness afterwards stated that his informant was wrong, there had been no case of typhoid, and the cases called so were scarlet fever.) He knows of one case of typhoid fever at Purfleet at the present time, and there are several cases of scarlet fever in the village now, 14,658–9. Purfleet is in the parish and registration sub-district of West Thurrock, and in the Orsett Union; he has nothing to do with the registration district, as he is only the medical officer for the barracks, 14,675–8. With regard to the outbreaks of typhoid fever on board the "Cornwall," he has occasionally visited the cases in consultation with the medical officer of the ship, and he has frequently seen cases for him in his absence. There is at present a case of typhoid in the quarters of one of the employés of the magazine, but he is a clerk in the employ of the London and Tilbury Railway Company. It is difficult to say when he contracted it, but he was at home when it broke out, 14,685–7. It is also difficult to attribute the outbreaks of typhoid on the "Cornwall" to any special cause. It is perfectly possible for a boy to have the seeds of the disease in him when he joins the ship, and communicate them to others. One case he believes was traced to that very cause. The "Cornwall" is the nearest training ship to the outfalls, 14,692–4, 14,697–8. He has about 300 people, men, women, and children under his charge. Of these 85 or 90 are troops, 14,688–91.

## Captain WILLIAM MILLER.

Captain of the Steamship "Castalia."

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has commanded the "Castalia" ever since she was launched, and she has been stationed in Galleon's Reach and at Erith ever since. The ship is moored in Erith Reach in the full strength of the ebb, 14,699–703. He sees refuse and grease floating down on the ebb, but no excrementitious matter. There are no traces of sewage at all, 14,704–8. In the summer of 1881 he noticed a slight smell from the river at about the first shoot of the ebb, but not in 1882, 14,738–11, 14,750–64. He has repeatedly bathed in the river on the top of the tide during the last two years between the ship and the shore. The water then is clean and salt. He bathed a few times only in Galleon's Reach, 14,712–8. With a north-west wind he notices very bad smells from the factories on the river bank, particularly from a glue factory. He has often had to shut his cabin door to try to keep them out. With a south-west wind he notices a smell from some brickworks, but it is nothing like the factory smells, 14,725–34. He was in Galleon's Reach for about a year and a half and has been stationed at Erith since October 1878. The water in Galleon's Reach was not so inviting to bathe in as the water at Erith, because there is not such a head of water on the top of the tide, 14,735–49. When the tide is running out strong he could not bathe comfortably, 14,765. The sewage is discharged just after high water, and he has watched for its coming down very closely, because it was so much talked about at Erith, but he has never been able to detect it. The "Castalia" was removed from Galleon's Reach just after the "Princess Alice" disaster, because it was said that the twin ship obstructed the view, 14,766–72.

Effect upon Health in the Neighbourhood of the Main Outfalls.—With the exception of about 12 nights he has always slept on board the "Castalia," and has enjoyed excellent health. His crew consists of two men and a boy, and with the exception of a boy who had rheumatic fever and who died in the hospital at Erith there has been no case of illness on board, 14,719–24.

## Mr. EDGAR DOGGETT.

Assistant Accountant in the Office of the Metropolitan Board of Works.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He has been employed in his present office for 20 years, and was in the Census Office for two years prior to that. During that time he had frequent experience in collecting and arranging statistics, 14,773–6. He assisted Dr. Tripe in his investigation of the sites which were likely to be affected by sewage (if there were any) by taking out the deaths which occurred in the various areas from the books of the Registrar-General, and visiting the localities themselves. He obtained further information from the office of the Metropolitan Asylums Board of the deaths from typhus, scarlet fever, enteric fever, and other diseases, except small-pox. These he tabulated and handed to Dr. Tripe, 14,777–82. The ordnance map of Erith shows a quantity of unoccupied space which is now built over. He has had this corrected to a certain extent on the map he produces. He went over the district shown on Dr. Tripe's

### Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

## Mr. EDGAR DOGGETT—*continued.*

Effect upon Health in the Neighbourhood of the Main Outfalls—*continued.*

spot map of Erith, and no part of Erith can be considered to be densely populated. The houses are closest in that part which is adjacent to the river, and that part, as shown on the map, is remarkably free from spots, 14,783–94, 14,805–6. He went over the Woolwich selected area twice, and the most densely populated part is also that nearest the river. The area of that part is 460 feet on the south by 500 feet on the north, and is about 200 feet deep, and contains about 96,000 square feet. The most densely populated part of both Greenwich and Rotherhithe is also situated near the river, 14,795–803. The river frontage at Rotherhithe is occupied by wharves and public-houses, and the area he has referred to comes close up to these, 14,804–7.

## Mr. FRANCIS MEAD CORNER, M.R.C.S., L.S.A.

Medical Officer of Health for the South part of Poplar.

Popular Evidence as to the Foul State of the Water in the River near the Main Outfalls.—In 1857 there were great complaints of the state of the river, and there was a very unpleasant smell arising from it, 14,835–6, 14,840. He sees no sewage at Poplar, but in certain portions of the river banks there is a certain amount of mud, but he has had no complaints of bad smells from those who live there, nor has he noticed any smell when in the houses overlooking the river. It is worst at Blackwall by Bow Creek, but the steamers going up and down seem to cleanse the banks to a great extent by their wash, 14,847–51. On the "Dreadnought" nothing offensive was smelt when 15 to 20 feet above the river, but at the surface of the water, or a few feet above it, it was distinctly nasty. The smell would be experienced at a higher level, he thinks, when the air was still, more so than when a breeze was blowing. This smell was noticed generally by all on board, 14,863-9.

Effect upon Health in the Neighbourhood of the Main Outealls.—He has been Medical Officer of Health since September 1877, and his district extends from Blackwall to Limehouse. He has also been in practice at Poplar for 25 years, and attends all classes, including those employed upon the river, in the docks, and in the factories which are on the river, 14,810–16. There are many thousands of people employed in the factories who mostly live in his district, but he does not find that typhoid, diphtheria, diarrhœa, or other zymotic diseases are more prevalent amongst the riverside districts than in districts more removed from the river. He compares the monthly return of deaths and infectious diseases for his district with those of other districts, 14,818–29. During the last five years there has been an epidemic of scarlet fever in the Isle of Dogs, but it was traced to a Board School, and was in no way connected with the condition of the river, 14,829. From 1857 to 1868 he was Resident Medical Officer of the Seamen's Hospital Ship "Dreadnought" at Greenwich, and there were from 150 to 200 patients on board. At that time the river was in a very bad state, but it had no injurious effects on the patients, the attendants, or the officers. There was a very unpleasant smell from the river, 14,830–40, 14,857–61. There were a considerable number of cases of typhoid fever brought to the ship, but, with one exception during the two years he was there, it never spread. At Dr. Lethby's request he reported these facts to him privately, but he does not know what has become of the communication. He has no evidence to show that the metropolitan outfalls have not had an injurious effect upon the health of the inhabitants of Poplar, and therefore it must not be accepted as a fact, 14,481–6. The same remark applies also to London as regards the condition of the river in 1857 and 1858, but, as a medical man, he should expect that the sewage in the river would be injurious to health. He would attribute the decrease in the death-rate of London more to the removal of the cesspool system and the more rapid removal of the sewage by the sewage system, than to the fact that the sewage was moved from London to Barking. He believes that the health of London would be improved by taking the sewage out of the river, but he has no facts to support it, 14,852–62.

## Mr. EDWARD EASTON.

Civil Engineer.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—For 25 years he has acted as Engineer for the Commissioners of Levels from Woolwich to Gravesend for the preservation of the banks, and consequently is well acquainted with the river; he is also Engineer to the Commissioners of the Navigation of Dartford and Crayford Creeks, and Engineer to the South Essex Waterworks Company. He has designed and constructed a good many engineering works of different kinds on both sides of the river. He thinks that when the Main Drainage works were designed no more suitable position for the outfalls could have been selected. The river at that time had no habitations on its banks from Barking to Erith, and on either side were vast marshes. From time immemorial there have been established on the river a variety of stinking trades between Greenwich and Purfleet, and if any nuisance arose from the sewage it would be overpowered by the existing nuisances. There is no change in the circumstances to induce him to alter his opinion now, 15,203–7, 15,292–4. Erith has enormously increased in size and population since the outfalls were opened, and there is a marked change in the character of the population also. There are a number of factories carrying on noxious trades between Erith and Woolwich, and he knows them all well from his frequent inspections upon the river, 15,208–9. The sanitary condition of Erith has in no way improved since he made his Report in 1877 or 1878, and the works which he recommended have not been carried out as they ought to have been. If anything, the condition is more aggravated now by the increase in the population, 15,210–11. The whole of the drainage of Erith was then and is now turned into the river. There are three or four outfalls at Erith. He recommended that the sewage of Erith should be deodorized by the lime process at Jenningtree Point, and then discharged into the river. That would cause no offence at all, while the discharge of sewage into the bay of Erith at all times is very objectionable. Only the other day he saw particles of sewage floating about, not Metropolitan sewage, which was going clean past the bay; it was not fresh sewage, and he is sure of it, 15,211–21, 15,346–53, 15,358, 15,398–402. He has read the evidence relating to the chlorine experiments, and, as far as he is able to follow the argument, it is not at all conclusive or worth very much. It is almost impossible to take samples enough to show what the chlorine really is in the river, and the admixture of so much fresh water, which comes into the river from Deptford to the sea, would have the effect of upsetting the calculation. The water can be seen running into the river at various points between these two places, notably from Greenhithe marshes and at Grays, 15,235–8. On the 4th June 1883 he visited one of the Erith outfalls which he had not been near since 1877. An iron pipe was broken, and it was discharging sewage at about half tide on the shore. He noticed the smells from the factories, particularly the fish manure factory opposite Erith. It was a bad day for smelling on account of the strong breeze. But all the factories can be smelt at Erith and other places very distinctly, some of the cement works being especially offensive, 15,281, 15,291, 15,354–7. He obtained a sample of the sewage as it was being discharged from the culvert, and it was all absolute sewage; it could not be highly diluted. It contained a certain amount of débris, wood and straws, &c., as well as some brownish solids which were no doubt excrement. There was a very marked line in the river where the sewage ceased, which he traced down the river until it lost itself. It was the same with the Crossness discharge, although he arrived two hours after the discharge had begun; the line was distinct, running parallel to the river, and then striking towards the shore and joining the other line which came from Barking, 15,304–9. He does not think there is any nuisance in the river at all arising from sewage; if there is a nuisance to the people of Erith, it is from the local outfalls, 15,346–53. The samples of water which he took on the 4th June were all forwarded to the chemists of the Metropolitan Board of Works for analysis. They were all taken at an uniform depth of 2 feet below the surface, and the exact spot, the temperature, and the time, was marked on each bottle, 15,362–7. The channel by Messrs. Beadle Brothers' wharf is in close proximity to the main outfall sewers of Erith, and he is not surprised to hear that the men working in that channel have complained of

Mr. EDWARD EASTON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

the nuisance, especially as No. 1 sewer pipe was broken, and discharging on the shore at half tide. It would be unpleasant, but not injurious to health, he thinks, 15,392–4.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—From observation, and not from actual measurement, he does not think there is a greater accumulation of mud in Erith Bight than there always has been. It varies at different states of the tide, and the accumulation is due to the eddy which exists there, the water from one and a half hours to three hours each tide being in a state of rest. Taking Erith causeway and the front of Erith, he does not think the accumulation of mud has increased. It is being deposited and washed away constantly, and there is not a gradual increase, 15,224–7, 15,310–17. Although it may have been stated in evidence, he is not aware that the lengthening of the causeway was due to the increase of mud, or that certain mooring buoys which used to be afloat at low-water are now aground. He does not live at Erith, and certainly is more familiar with the mouth of Dartford Creek. He never was very frequently at Erith, though he knows it well. His information as to any deposit or accumulation of mud is derived more from reports which he would receive from the Inspector to the Commissioners of Levels, 15,228–32. The only remedy to get rid of these accumulations would be to alter the shape of the river, but there is no doubt that the mud shifts from tide to tide and according to the quantity of water coming down the river, 15,233–4. In speaking of the mud in Erith Bight, he refers to the shore of the river and not to mud banks in the river, 15,239, 15,310–11. He produces and hands in a plan which shows the difference of the line of mud bank between 1862 and 1879, which was prepared in connexion with the improvement of Dartford Creek. He does not believe that there has been any change during all those years. He is unable to say whether there has been any change since 1879, 15,240-3, 15,372–8. On the 4th June 1883 he obtained a sample of some sand at Crayfordness which was being dredged up. It was bright sand covered on the top with a very small thickness of black material or mud. It had no smell whatever, nor could he detect any smell when the spoon came out of the water. The sand wa, suitable for building purposes, or cement when washed, 15,272–9. He then obtained a sample of the mud at Erith Causeway, which he washed, and found it contained about 40 per cent. of sand, and the rest was composed principally of coal dust, bits of brick, &c. An analysis has been made of the mud, and it will be laid before the Commission. A pole was pushed into the mud in several places along the causeway, but he could detect no offensive smell on the pole, 15,281–9, 15,337–45, 15,368–71, 15,387–91. At Cubitt Town he obtained a sample of mud from a dredger nearly opposite the Thames Soap Works and the Greenwich Candle Works. That sample has been handed over to the chemists for analysis. He obtained other samples, but he will not specify these, 15,281, 15,289–90, 15,295–6, 15,368–71. Assuming that the sewage was discharged upon the ebb from the main outfalls, he cannot see how it could be deposited in Erith Bight; but, discharged as it is on the flood and mixed with the water of the river on its way down, some portion of it so mixed may find its way into Erith Bight when brought back with the tide. As at present discharged, it cannot flow into Erith Bight on its way down the river, nor can the solid substances in suspension be so deposited. Any deposit of animal matter at Erith must arise from local causes, viz., the Erith drainage, 15,297–301. He saw the Erith mud on the 4th June, but he has made no regular inspection of it since 1878, and he does not believe there is any more mud there now than there was in 1879. There is a small "hard" close to the head of the causeway, which is clean and has no covering of mud over it, and it extends about one-fourth of the way down to low water. There is no beach at Erith, but the shore slopes down nearly perpendicularly to the foreshore, 15,312–36. The blue line on the map he handed in shows the line of mud as taken from the Ordnance map of 1863 to 1866, and the black line represents the mud in 1879. He does not remember whether 1863 to 1866 were dry years and 1879 a wet year, but it would not make much difference, because the Dart is one of the chalk streams, and it is a tidal river as well as far as Dartford, so that

Mr. EDWARD EASTON—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*continued.*

the quantity of water issuing from Dartford Creek depends more upon the tide than it does upon the upland water, 15,372–9. The Thames water contains a certain quantity of suspended matter, part of which is of natural origin, part due to the suspended matter contained in the sewage, and part due to the solid matter which has been washed from the banks, and in places where there is slack water there is a tendency for this to deposit, Erith Bight being such a place. He would expect to see it also more or less all down the river. Where the current is slack the deposit would be composed of fine stuff like the sample he took at Erith Causeway; where it runs more freely the deposit is coarser like the Cubitt Town sample, and where the current is quicker the deposit approaches sharp sand and gravel. In every case probably upon the top there would be some traces of sewage, 15,383–6.

Effect upon Health in the Neighbourhood of the Main Outfalls. — Erith is not an unhealthy place, decidedly. If it is not all that can be desired, he would attribute it rather to the sanitary condition of the town itself than to the Metropolitan outfalls, 15,222–3.

Distribution of the Sewage in the River by the various Motions of the Water. — He has read the evidence relating to the chlorine experiments, and, as far as he is able to follow the argument, it is not at all conclusive or worth very much. It is almost impossible to take samples enough to show what the chlorine really is in the river, and the admixture of so much fresh water which comes into the river from Deptford to the sea would have the effect of upsetting the calculation. The water can be seen running into the river at various points between these two places, notably from Greenhithe Marshes and at Grays, 15,235–8. On the 4th of June last he went down the river, accompanied by Mr. Chatterton, and arrived at the Barking outfall half an hour after the reservoir had been discharging. On the first quarter ebb he put a float into the middle of the sewage close to the shore and to the northern outfall, and then followed it in a small boat, 15,244–53. The exact spot where the float was put was right over the discharging point. About half the contents of the reservoir had been discharged, and the smell was very strong, but constantly it was overpowered by the smells from the chemical and guano works, which were brought up on the east wind, more particularly Lawes' Chemical Works, 15,254–7. He followed the float until it had passed the guano works just below Barking Creek, and then went to Crossness, where he put another float into the river, a little below the outfall, in the flow of the sewage. It took a course parallel to the shore. By this time the Barking float was very nearly off Dagenham Jetty. He then went to Erith Bight and put a third float into the river, which remained stationary, as nearly as he could tell, while the northern outfall float had travelled about half a mile beyond it. It was now about half ebb tide, 15,258–66. The third float was put in about 120 yards from the shore, just opposite the Upper Ballast Wharf; one yacht was facing up stream, and all the rest were pointing in the opposite direction. There was not much wind, so he does not think the yachts were either wind-rode or tide-rode, but, as the float was stationary, that it was dead water at the time. This float was taken up, as it was no use trying further experiments at that time. The Barking float at 4.46 p.m. was in mid-stream off Crayfordness, and from a sample of water which he took there was no trace or smell of sewage whatever; all the Metropolitan sewage had entirely disappeared. At 5.5 p.m. the float was in mid-channel at the top of Long Reach, and here he took it out of the water, 15,266–72. He thinks the present mode of discharging the sewage at high water is the best way that can possibly be conceived, because it is then carried straight down the river. There might be times when it might be discharged before high-water, but it would depend very much upon the tide, 15,292–4. No better position for the outfalls could be found between Greenwich and Gravesend, 15,302–3. He only used three floats on the 4th June, 15,359–61. The third float, which was put into the river in Erith Bight, he explains, was not actually in the sewage from Crossness outfall, but near the shore, the sewage being out far beyond it, 15380–2. The easterly wind blowing would have an effect upon the water, but not upon the floats, which followed plainly in the stream of the sewage. The Crossness float was lost in the line of mid-channel, 15,395–7.

## Mr. ROBERT GORDON TATHAM, M.R.C.S., L.S.A.

Surgeon to the Honourable Trinity Corporation and Surgeon to the East and West India Dock Company.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—For the last two or three years he has heard no complaints as to the bad state of the river, but, prior to that, there were complaints. In hot weather he has noticed sometimes a little bad smell from the river, both on it and on the banks towards Blackwall; occasionally he has to go on the river, 15,432–8. Forty years ago reeds and rushes grew on the banks of the Thames and up the River Lea, but they have entirely disappeared. In 1849 he remembers taking home 50 specimens of plants growing upon the banks of the Lea in the immediate neighbourhood of the Thames, jnst above the Trinity Wharf. He can give no opinion as to what caused the death of the plants, but the river was in a bad state from the London sewage before the outfalls were opened. He noticed it when crossing the river on his way to Greenwich, 15,481–90.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud in the Neighbourhood of the Main Outfalls.—For the last few years there has been a denudation of mud on the side of the river. As a boy he remembers the shore round the Isle of Dogs and opposite East Greenwich was very muddy, with reeds and rushes growing in it, but since the introduction of small tugs, principally, the mud has gradually washed away, leaving most parts clean to the gravel. In consequence there has been an increase of matter in suspension in the river, but during the last two or three years the water has been much clearer than it used to be. He thinks a good deal of the mud in suspension has either settled down, forming mud shoals, or else found its way out of the river, 15,455–60, 15,491–3. He has not noticed any smell from the mud near the entrance to the docks lately, nor has he heard any complaints from the men, though there were a good many complaints two or three years ago. The smell referred to by Captain Hussey might have been caused by letting the river water into the docks through the sluices, which would stir up the mud and so cause the smell complained of. This would probably pass off when the water became quiescent, and so he would not notice it, 15,494–5.

Effect upon Health in the Neighbourhood of the Main Outfalls.—He has been surgeon to the Trinity Corporation for more than 20 years, and has lived near the river all his life. He now lives at Poplar, 15,403–6. The Trinity Corporation has a wharf at Bow Creek, where the Lea joins the Thames, and it faces both rivers. The Trinity men are employed mostly in lighthouses and on board the light-vessels in the London district. Those on the light-vessels are kept two months on board, and then take a month's duty at the wharf. When on shore, they sleep in their own houses in the neighbourhood of Blackwall and Poplar, the majority of them living within half a mile of the Thames, 15,407–14, 15,461–72. There are about 200 men so employed, he believes, and they have very good average health. He attends their families in his private capacity as a medical man, 15,415–17. He has not been able to attribute any illness to emanations from the river, and he does not think they have suffered at all from zymotic diseases. The superintendent, who lives on the wharf, had an outbreak of scarlet fever amongst his children, but it was attributable to the defective drainage of the house itself, which has been pulled down, and another house built. None of the men employed on the wharf were attacked with scarlet fever, 15,418–24. There is a hulk lying off the wharf on which two men live, but there has been no zymotic disease on board. He would know if any case broke out, because he attends all the men. They are constantly going to and from the Trinity steamers in boats, 15,425–31, 15,473–4. He has also between 700 and 800 labourers employed by the East and West India Dock Company under his care, and they all reside in his district. These men work at the docks all day, and sometimes all night. There has been no prevalence of zymotic diseases amongst them, and although there have been 31 deaths in six years amongst these 700 or 800 men, not one was from zymotic disease. No case could arise without his knowing it, and it would not be removed to a hospital without his order. The superintendent and storekeeper, with their families, sleep on the premises, 15,439–50, 15,496–500. There may be a few more deaths which take place in hospital from accidents. A few men might be attended by a club doctor, but there are not many, 15,450–1. His house is about a quarter of a mile from the river, and he was born close to where he lives. He has never suffered in health from any bad emanation from the river, 15,452–4. The men employed in lighthouses are changed every month, and work at the wharf when on shore, sending stores, &c., all round the coast. Some are also employed in the Trinity steamers. The light-ship men for the greater part of the year are in good fresh air at sea. He examines the men and certifies them to be fit for the service before they are engaged, 15,461–72. The dock labourers belong to a provident society, to which he is the medical attendant, and he examines them before they are engaged by the dock company. He keeps a record in his diary of all the diseases the men are suffering from, but he makes no report, 15,473–80. All the men (Trinity and dock) are at work from eight in the morning in summer, and nine in the winter, until 4 p.m., nominally, but it is frequently six o'clock before they leave. In fact, from sunrise to sunset they are at work, except the gatemen, who have to take in vessels day and night. They are at their posts for about four hours each tide, 15,496–500. These men mostly live within two miles of the river, though scattered about; he practises generally in the neighbourhood, but the people are very healthy about Poplar, 15,501–4.

## MR. WALTER DICKSON, R.N.

Medical Inspector of Her Majesty's Customs.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has held his present appointment 21 years, and occasionally he has noticed offensive smells coming from the river, but very rarely. There is a mud bank in front of the Custom House quay, which sometimes smells in hot weather, and in other parts of the river he has noticed an unpleasant smell when the mud has been stirred up by steamers. The river has considerably improved both as to smell and appearance during the last 10 years as compared with the preceding period. He seldom goes farther down the river than the East India Docks. If he goes to Gravesend, he travels by train. He has made inquiries from the Customs officials, and they say there is no great nuisance experienced from the river by the people on board the ships, 15,537–45. His predecessor, Dr. McWilliam, called special attention to the foul state of the river and the docks in June 1859. They began to smell most offensively, and serious apprehensions were entertained for the public health, 15,529–30, 15,548–51. He has ascertained that the smells which are noticed now at the Custom House are due to Billingsgate market, 15,549.

Effect upon Health in the Neighbourhood of the Main Outfalls.—Part of his duty is to supervise the health of the subaltern custom house officers of the port of London, consisting of about 1,000 men. The time these men are on duty varies from eight to 12 hours during the day, but many have night and Sunday duty as well, when they board ships at Gravesend, for then they have to remain on board until the cargo is discharged. The night duty may be said to be entirely on the river, and about 500 men are engaged in it, 15,505–10, 15,512. About three-fourths of the whole number are employed on or upon the margin of the river. Then a section of the men are called watermen, and these are very much on the river, their duty being to "rummage" ships for contraband or smuggled goods. All these men have very laborious duties to perform, and are much exposed to the weather and to changes of temperature, 15,511–15. Considering the nature of their duties, the health of the men is remarkably good. Eliminating accidents, the proportion of sick is about 3½ per cent. Zymotic diseases are almost unknown amongst them. There were two fatal cases of cholera within the last 26 years, and they were sporadic. One was due to great fatigue during the great fire at London Bridge in 1861, and the other was in 1866, when cholera was epidemic in London. This case was self-induced. The man was in perfect health and took medicine, which brought on profuse purging and turned to cholera, 15,516–26. About 250 of the men live at Gravesend, and their health is very good, as, in fact, is the health of the whole body

MR. WALTER DICKSON—*continued.*

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS—*continued.*

of men. He has never been able to trace any case of zymotic disease originating or caused by the condition of the river. He would know of any such cases, because the men cannot be withdrawn from duty without his knowing it. They are treated most liberally, and have every encouragement to apply to him. Pay during sickness is allowed for six months without any stoppage, the men are treated free, and have medicine supplied to them, 15,521–28, 15,535. He used to cross the river in boats, but has discontinued the practice owing to the danger on account of steamers. He is not much on the river now, 15,531–2. Except at Gravesend, the men's residences are widely scattered over the suburbs, 15,533–4. In 1858 and 1859, when the river was in such a foul condition, his predecessor reported that diarrhœa was not more prevalent than in any other year, 15,536. In 1859 there was less sickness amongst the men than in 1858, when the river was not so offensive, 15,550–1. He has made reports of a very similar character, going minutely into the effect of seasons, &c., upon the health of the men. A cold winter is the most injurious factor of disease, 15,552–3.

## MR. WILLIAM JOSEPH DIBDIN, F.C.S., F. Inst. C.

Chemical Assistant to the Metropolitan Board of Works.

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—For five years he was assistant to the late Mr. Keates, and at his death he succeeded him as chemical assistant to the Metropolitan Board of Works, 15,554–7. He made a series of investigations as to the condition of the river, especially with respect to the effect produced upon the water by the sewage which is introduced into it from the Metropolitan Board's outfalls. All the analyses he has made are recorded in a book which will shortly be handed in, and a further series will be handed in by Dr. Dupré, 15,558–61. The first series was made during the first three months of 1878, the second series was made in October and November 1878 in consequence of the "Princess Alice" disaster, and in 1880 the investigations were renewed. In making these analyses, he wished to ascertain whether the river water was impregnated with sewage to such an extent as to be injurious to the health of those travelling on the river or living in its neighbourhood, 15,562–4. He adopted Wanklyn's ammonia process, which is a delicate and trustworthy mode of ascertaining the amount of impurity in the water. It is the best he knows, and is used by Professor Way. It gives the relative, not the absolute, amount of organic matter, 15,565–9, 15,727–8. A number of samples of sewage were taken at Barking and Crossness from the sewers as it flowed into the reservoirs, at intervals of four hours over the 24 hours, at each outfall. He obtained 184 samples, and the average quantity of albuminoid ammonia per gallon of London sewage in the series of samples is equal to ·383 of a grain per gallon. Some contained a much higher quantity, others much less. The samples from the north and south are separate. The details of those analyses he hands in. (*See* Appendices B.X. and B.Y.), 15,570–8, 15,736, 15,818–35. He used the ordinary Thames filtered water as supplied by the water companies, which contains ·005 of a grain of albuminoid ammonia per gallon, 15,579–80. He then took a number of samples of water from the river during the months of March, April, and May, every four hours at first, and subsequently at hours varied so as to follow the tide, by which means he was able to get an absolute average of the quantity of putrescible matter in the sewage itself. The water samples were taken in the line of the sewage itself, and on each side of it, 15,581–9, 15,867–75. The details of these analyses are given in Diagram No. 1, and on page 11, Nos. 203 to 206, in the Tables, 15,590. On the 15th October 1878 the amount of albuminoid ammonia on the shore side of the line of junction of sewage and river water was ·254, and on the mid-stream side it was ·067. On the 11th August 1880 the amounts were ·207 and ·027 respectively. These two last samples were taken from the bow and stern of the boat, which was drifting at right angles to and in the stream of sewage. There was no special reason for the selection of these dates, 15,591–6. The samples taken in 1878 were taken in consequence of the complaints as to the state of the river at the time of the

MR. WILLIAM JOSEPH DIBDIN—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

"Princess Alice" disaster in the previous month, 15,597–9. Diagram No. 2 shows diagrammatically the analyses which are given in Table No. 5, Nos. 207 to 225. Four series of samples were collected in the line of sewage flowing from the northern outfall. The object of the diagram is to show the decrease in the quantity of albuminoid ammonia, yielded by samples collected in the line of sewage flow from the northern outfall on the 15th October 1878, the 13th March 1882, and 11th August 1882. The samples taken on the surface and near the bed of the river show very little difference, showing that the diffusion of the sewage and river water is complete, 15,600–7, 15,876–8. With respect to suspended matter, there is no doubt that the heavier portions, such as sand, would have a tendency to deposit, and therefore the amount of solid matter found in the samples would be greater in those taken near the bed of the river than near the surface, but the suspended matter in the sewage is very much lighter, about half the gravity of the river suspended matter, and the uniformity he referred to refers to the solubility of the albuminoid ammonia. In making his analyses, he allowed the suspended matter to settle, and examined the clear water; in many cases the suspended matter was examined separately. The amount of chlorine increases as the sewage decreases, but the chlorine is not the same at different depths; there is, however, a very close accordance. For example, on the 11th August, at the surface, the chlorine immediately off the outfall was only 40 grains, and 3 ft. from the bottom there were 138 grains; below Barking Creek, at Lawes' chemical works, the chlorine was 361 and 394 grains at the surface and bed of the river respectively, while at the Powder Magazine there were 392 and 398 grains, showing that the mixture was still more complete. At Crossness the difference was slightly greater. There is always an excess of chlorine at the bottom independently of sewage, but a few hundred yards from the outfalls the chlorine is tolerably constant, 15,608–14, 15876–8. The quantity of albuminoid ammonia may be taken as an index of the quantity of putrescible organic matter which is present in the sewage. He is speaking of "sewage" when it is in such a condition that it yields on analysis a certain quantity of albuminoid ammonia. When it no longer yields it, he speaks of it as water, 15,615–21. His object in putting forward the tables is to show what the sewage is in its pure state, and what it becomes when it is poured into the river. By putrefaction and oxidation it undergoes a very rapid change; as the putrescible matter decreases, so the albuminoid ammonia decreases, 15,622–36. The samples were collected in the line of sewage flow from the northern outfall, which is plainly distinguished from the river water as far as False Point, but beyond that, owing to the particular configuration of the river, the sewage is distributed over the whole width of the river. Occasionally it can be seen plainly further down, 15,637–41. Diagram No. 3 shows the amount of albuminoid ammonia yielded by samples collected in the line of sewage flow from the Crossness outfall on the 15th March 1882. It will be seen that the albuminoid ammonia decreased in quantity from ·336 grains per gallon down to ·028 grains per gallon at Jenningtree Point, 15,642–3. Diagram No. 5 shows the quantity of albuminoid ammonia in a number of samples which were taken off Woolwich Arsenal at high-water and one hour after high-water from the 10th August 1880 to the 18th October 1880. The amount of chlorine is also shown, which gives a rough idea of the proportion of fresh and sea-water. The analyses for chlorine and albuminoid ammonia were taken from the same sample. The maximum of albuminoid ammonia was ·042 on the 12th October, and the minimum was only ·021 on the 12th August and the 23rd September. When the chlorine rises it indicates that the proportion of sea-water coming past the outfalls is greater than the water coming down from above, and when it falls the land-water is greater, and the pollution also is greater, indicating thereby that the main causes of pollution are rather to be sought above Woolwich than below. It is curious that when the albuminoid ammonia was at its maximum the chlorine was at its minimum, showing that the floods had reduced the proportion of sea-water to an abnormal extent, 15,644–65, 15,860–3, 15,879–88. Diagram No. 6 represents a series of samples taken off Woolwich Arsenal an hour before high water from the

MR. WILLIAM JOSEPH DIBDIN—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

15th August to the 5th December 1881, and the analyses are given on Table 3, Nos. 95 to 102. The red line represents the mid-stream sample, and the blue line the sample vertically over low-water mark. There is less pollution in the mid-stream samples than in those near the shore. The curve represents the relative amount of the organic ammonia. The same tendency is shown here as in the case of the other samples, viz., the lower the chlorine, the higher the pollution, 15,666–73, 15,879–88. Some samples taken in October 1880, and in November and December 1881, are some prominent instances indicating that the water at Woolwich is largely affected by some source of contamination above Woolwich which he is unable to explain. The mean quantity of albuminoid ammonia off Woolwich from samples taken in 1878, 1880, 1881, 1882, and 1883 respectively, was ·0317, ·0286, ·0373, ·0277, and ·030; the variation is very slight, but it is in favour of the present period, 15,674–5. Diagrams Nos. 7, 8, and 9, represent the amount of albuminoid ammonia found in samples collected at half-flood and half-ebb upon the surface of the water and two feet above the bed of the river on the 27th July and 3rd August 1882, at Blackwall, Woolwich, Barking Creek, and Erith. From the result of these analyses there is no very great difference between the top and bottom of the water, and the only conclusion to be drawn from them is that the mixture is complete, 15,676–7, 15,901–8, 15,910–12. On the 24th August 1882, samples were collected during three-quarters ebb, 200 yards from either shore, and in mid-stream off Crossness Point and Erith Causeway, to ascertain whether there was any difference in the water. The result shows that it was the same on either shore at Crossness Point, and rather better in mid-stream, and at Erith the mid-stream was still the best, but the variations are very slight. Diagram No. 10 gives these results, 15,677*a*. Diagram No. 4 shows the samples taken upon the 31st August and 1st September 1882, at all periods of the tide. On the 31st at low tide the river, having received the sewage, was at its worst, it was improved two hours later by the water from below, at high water it was at its best, and became worse again at quarter-ebb. On the 1st September, after having been scoured by the very high tides of the preceding day, the river was a trifle worse at half-ebb than it was at a corresponding time on the 31st; it was about the same at three-quarters ebb, and considerably better at low-water, notwithstanding the sewage; but at high-water the impurity increased to a maximum for the day. From all these analyses, speaking generally, it is manifest that the organic pollution of the Thames for the six years over which they extend is practically constant, and not an increasing quantity. The figures at Woolwich with slight variations would apply to any other portions of the river, but the average result of it all is that it is very much the same during the period of six years, 15,678–82, 15,879–94. The various analyses show that the organic ammonia yielded by samples collected above Teddington Weir is only from half to a third of that in samples taken at Woolwich; so, if the additional quantity of organic matter which the river receives in its downward course from the shipping, &c., be deducted, it will be seen at once that, if the water at Woolwich and other points in the neighbourhood of the outfalls is contaminated by the Board's sewage works, it can only be to a trifling extent, not greater than that present in ordinary London drinking water, 15,683–91. Table No. 5 gives the analyses of some samples in the Victoria Docks, Deptford, Bow, and Barking Creeks. The water in these places is worse on the whole than the water in the Thames in mid-channel. He will furnish the exact spots where the samples were taken. He has taken other samples (or they have been taken for him), but he can prove the collection of all the samples in his tables, 15,692–702, 15,716–26. Some doubt having been cast on a sample taken in the Victoria Docks in 1878, he had a sample collected yesterday morning at 8.30 a.m., 100 yards inside the inner lock, 20 minutes before the gates were opened, so it may be accepted as a fair sample of the dock water. It contained ·059 grains of albumenoid ammonia and 150 grains of chlorine per gallon, while the 1878 sample contained ·066 grains of albuminoid ammonia. This proves that the water in the Victoria Docks contains more than twice as much nitrogenous organic matter than the general average of Thames water in mid-stream in the neighbourhood of the outfalls, say from Woolwich to Erith. The docks no doubt contain

MR. WILLIAM JOSEPH DIBDIN—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

impurities from the shipping, 15,705–15. He has compared the water in the Thames with the water in the Victoria Docks, and goes through his tables, showing the quantity of albuminoid ammonia and chlorine each sample contains, 15,716–26. He thinks he can show by his own evidence, and that which is to follow, that the albuminoid process is a very reliable test not only for sewage but is a guide used almost universally by chemists as a test of the quality of ordinary drinking water, not only in England, but elsewhere, as an indication of relative purity, 15,727. It is found in almost every sample of water, even in distilled water a trace can be found, 15,728. There are several other methods for estimating the quantity of organic carbon and organic nitrogen, for example, the permanganate process, but when a mixture of river water, sea water, sewage, &c., is to be dealt with he knows of no better method than the albuminoid process, 15,729–30. He has not compared his results with those of Professor Heaton, because their methods of operation were different; Professor Heaton included a great quantity of suspended matter in his albuminoid ammonia, while he allowed the suspended matter to settle and then drew off the water. His figures, roughly speaking, correspond with Professor Way's, though the results are given in parts per 1000,00, and his in grains per gallon, 15,731–6. On page 13 of the Tables Nos. 246, *et seq.*, a number of analyses are given of sewage from sources other than the Metropolitan Board's outfalls. The average results are given on page 6, 15,736. It will be remembered that the other side stated that the average quantity of suspended matter in sewage, taking wet and dry weather together, was nearly 50 grains per gallon, and there was some controversy about it. To settle the question, he had a series of samples taken in March, April, and May 1883, and the average quantity of suspended matter amounts to 27·39 grains per gallon, which makes a material difference as to the quantity of solid matter discharged into the river, 15,736. On the 16th August 1882 he noticed a discharge of sewage into the river at Chiswick, and obtained a sample of sewage and water, as he could not get a sample of the pure sewage, and on analysis it yielded ·31 grains of albuminoid ammonia, which is nearly equal to the amount at the Board's outfalls. It is not surprising, therefore, that sewage is should have been *traced* as high as Chiswick, 15,737. At Beckton Gas Works and at Erith a considerable quantity of sewage is discharged into the river The discharge on to the foreshore from the Erith outfalls was far more foul than anything coming from the Board's outfalls, and when exposed to a hot sun would give off most offensive odours. A sample taken yielded 3·70 grains per gallon of albuminoid ammonia, and the odour from that sample was the worst he ever analysed. He has also seen lying on the beach at Erith slaughter-house refuse of all kinds, solid sewage, and other matters, and although the day was comparatively cool, the atmosphere was exceedingly obnoxious, and is quite enough to account for the smells which have been so much complained of at low-water, 15,738–44, 15,916–21. He has for the last six years made a number of chlorine determinations all over the Thames, but in no case has he found it ever exceed 5 grains per gallon at London Bridge. He twice obtained 4 grains, but it was on occasions of exceedingly high tides. The inference he draws from that is that the quantity of sea water at London Bridge is very minute, 15,745–6. He has inspected the river upon a number of occasions, and has taken some pains to ascertain the temperature of the water between Greenwich and Erith, and although it has sometimes been nearly 70 degrees, the odour from the water has not differed from the water at Teddington or Southend. When shaken up in a jar, he has noticed a "sedgy" odour, but never anything that would indicate sewage unless he has actually been in the line of the sewage. The smell from the factories is very strong, and he has never been down the river without smelling one or more of the factories according to the direction of the wind. At times this smell is extremely nauseous, and he can quite understand that the fishermen should have imagined them to come from the river, 15,771–2, 15,946–9. He has not heard that "Wanklyn's process" has been given up by a great number of chemists. It is a rapid and easy way of getting at a result, but it is not always reliable. A great many still use it, and possibly a great many do not. There are very few processes which give you the actual composition of the organic matter in a sample of water, but he thinks

Mr. WILLIAM JOSEPH DIBDIN—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

it is reliable enough to indicate the source from which the albuminoid ammonia comes, 15,775–82. Albuminoid ammonia is now taken as an index of the amount of putrescible organic matter, and what is likely to become putrescent. It only takes into account the nitrogen, not the carbon. A great deal of albuminoid ammonia comes from things which are not, nor are likely to become, putrescible. Some bodies yield half their nitrogen, some their whole nitrogen, as albuminoid ammonia, while others which have nitrogen yield no albuminoid ammonia at all, 15,783–90. He has never tried uric acid or urea for nitrogen which yields ammonia. There may be elements of pollution in the water which may yield no albuminoid ammonia, and there may be also a great deal of albuminoid ammonia which results from causes quite independent of sewage pollution, but in the case of the Thames he does not think there are, 15,791–8. Peat yields an enormous quantity of albuminoid ammonia, but he does not consider that its presence in the Thames is due to any other cause than sewage. The quantity varies considerably if the circumstances are not regarded, but if the state and time of the tide and the rainfall be considered, it does not vary capriciously, 15,799–811. He has tried the combustion process, but it is neither so simple, nor so quick, nor so reliable, as Wanklyn's process. He believes many chemists use the combustion process, but it is open to so many sources of error that it is hardly worth while adopting it, 15,812–17. Although he took 181 samples, one sample would have been sufficient to evolve his theory if he had obtained a mean sample, but if the sample is an exceptional one, the result would be fallacious. He found very great fluctuations in his results of albuminoid ammonia. His reason for mixing three samples together was to get fair average samples, as the strength of the sewage varied according as it was day or night sewage. It was never the same strength for eight hours together. It would, in addition, have required a very large staff of assistants to examine each sample separately. Page 7 in Volume 2 of the tables gives the strength of each sample separately, but he has not ascertained the quantity of albuminoid ammonia, as it would have occupied too much time to do this when 24 samples were collected each day, 15,818–34. A considerable quantity of rain fell, as he shows on page 7, during the time the samples were being collected, 15,835. The samples in 1878 were taken to test the accuracy of Captain Calvert's statements as to the condition of the river, and those samples which he analysed personally are entered in Table I. Many others were taken and analysed by other people. The number he took was 22, and the samples are spread over the whole of the year and in different places. The state of the tide is given in most cases, and he supplies the deficiencies now, 15,846–58. He selected Woolwich as his place to make the observations recorded in Table 2, because many complaints were made as to the state of the river then. The deduction he draws from page 3 at Woolwich is that the contamination of the river at that point is so small as to be immaterial to the question of its giving forth emanations which are likely to be injurious to health, 15,859–61. By taking high-water and an hour after high-water, which is the water from below the outfalls, one would expect it to be the horrid polluting stuff that it is said to be, but the figures show that it is not so, and that at high-water on 13 days out of 20 the samples contain the least pollution when they ought to contain the most sewage, 15,862–6. As a rule, the chlorine increases with the spring tides, which is at the time of the full moon. On the 16th, 19th, and 20th August, when the tides were approaching spring tides, there was a depression of chlorine, 15,897–900. At Barking Creek the amount of albuminoid ammonia at half-ebb and half-flood is about the same, but above Barking the half-flood is worse than the half-ebb. The difference, however, only amounts to ·0020, which is not so much albuminoid ammonia as is found in London drinking water, and, therefore, is of no moment, 15,901–5. The samples on which his Volume 1 is founded are single samples, not taken across the river, except the Erith ones, which were taken at three different points across the river. These were taken at the surface, and halfway down, so there were six samples which he mixed in order to get a fair example of the condition of the river 15,909. The mixture of sewage and sea water turns the sulphates into sulphides. The organic matter

Mr. WILLIAM JOSEPH DIBDIN—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

and the sulphates react upon one another, and sulphides are formed. Then the ferruginous clay which is suspended in the river water acts as a purifying agent by absorbing the sulphuretted hydrogen so formed, and in that way the black colour of the mud is obtained. Sulphuretted hydrogen is not given off, because it is immediately seized by the clay in suspension, 15,913–15. He does not think the sulphuretted hydrogen is ever given off again, because oxidation is going on, and the iron is converted into oxide of iron, and the sulphur is set free, 15,925. He knows of no method of analysis that gives certain absolute indications as to the source of the organic matter present in the deposit; they are all relative. Albuminoid ammonia, which he took for comparison with sewage, yields a certain standard quantity, and albuminoid ammonia may be found where there is no sewage, but not on the Thames to any appreciable extent, 15,922–4. Ammonia would be got as free ammonia from the urine in the water; but if Wanklyn's instructions for analysis were carried out, it would all be destroyed in the preliminary boiling, 15,926. There is a large amount of vegetable matter in the Thames, and a certain amount of albuminoid ammonia is derived from peat at Teddington, but he should not consider it a peaty river, and it is well known that there is a considerable quantity of sewage discharge into the river above Teddington, 15,927–8. He does not know that anything is given off from the sewage in the river to cause the smell; you smell it, as it were, like the smell of a rose, for example. It ceases to smell when the matters which give rise to that odour are destroyed either by oxidation or other cause. It is destroyed as sewage, though the materials remain, and the carbon of which a part of the sewage consists is converted into carbonic acid gas. That would be dissolved in the river water, and probably unite with lime or other substances to form carbonate of lime or chalk. Some, no doubt, would go into the atmosphere if the water was overcharged with it. The ammonia would in part be lost by evaporation, and in part be converted into nitric acid, and combine with the alkaline salts which are found in the river to form nitrates. The solid parts of the fæces which are soluble would enter into solution with the river water and go out to sea, and the insoluble portions would be held in suspension and carried away with the other suspended matter; and, as the specific gravity of sewage is little more than half that of the river suspended matter, it is reasonable to suppose that, if the latter is carried out to sea, the sewage would also. The heavier portion, such as sand, &c., would be deposited if an opportunity was given to it, 15,929–45, 15,954. The sewage when first discharged from the outfalls smells, and the smell can be detected on a calm day, when in a boat on the river, for 600 or 700 yards; but on a cold, windy day, with the water a little rough, the smell disappears in an astonishing short time. There is no smell on the return of the tide, for the sewage has then mixed with the water and is lost, 15,946–9. Water, when it has lost its due proportion of oxygen, does not become fœtid or objectionable, because it rapidly re-absorbs oxygen from the atmosphere. It could be drunk without injury, if it contained nothing injurious to health, when deprived of its oxygen; but the very fact of its absorbing oxygen shows that the water had contained matter which ought not to be present in drinking water. At Gravesend, he thinks, there is a little sewage still unoxidised, 15,955–62. He has dealt in the albuminoid ammonia estimations with that quantity of impurity which is in solution both in the sewage and in the river water, and that quantity, he considers, is the most important. The average amount of suspended matter in the sewage he has shown to be equal to 27·29 grains per gallon, and the sewage is discharged into over 200 times its bulk of river water, and the mixture is complete. He has not dealt with the suspended matter and the question of its disappearance, as that has been considered by others who will give evidence on the subject. He has only dealt with the matter in solution, 15,963–5. With regard to the fact that fish cannot be kept alive in the wells of fishing boats above Gravesend, he attributes it to the absorption by the sewage of the oxygen in the water, and so rendering the water in a condition which is not fit for sustaining the life of a fish. They require oxygen for breathing just as much as human beings do, and without it they suffocate. Indirectly it is due to the sewage, but not directly, 15,950–3.

## Mr. WILLIAM JOSEPH DIBDIN—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—The results of his analyses, as regards suspended matter in the London sewage, are given in Volume 2, which he has laid before the Commission, and the total quantity of suspended matter in the London sewage in April and May 1883 is equal to 27 · 39 grains per gallon. He has taken the effect of the rainfall into consideration, and it is shown in the tables. The samples were taken every four hours. At Barking a sample was taken from the lip of each of the three outfall sewers, and then they were mixed together. At Crossness the samples were taken just as it came from the pumps, so that it was thoroughly mixed. He thinks it represents the average as nearly as it could be obtained, 15,747–53, 15,836–45. He has taken samples of mud from the various banks in the neighbourhood of the outfalls in 1883 as nearly as possible in the spots where samples were taken in 1879, and he also analysed them in the same manner. He finds generally that there is no practical difference whatever in the composition of the mud. He has not made any comparison with the mud near the outfalls, and that mud which is not subject to the influence of the outfalls, as the matter was gone into so thoroughly at the time of the Mud Inquiry, 15,754-9. At Erith the mud six inches below the surface is the same as the ordinary Thames mud, but, when skimmed off the surface, it contains rather more organic matter than it does below. The quantity of organic matter in the sewage mud from the floor of the reservoir is 34 · 68 per cent., and the surface sample at Erith Pier contains 14 · 28 per cent.; but the nitrogen in the organic matter in the sewage mud is only 5 · 34 per cent. against 4 · 69 per cent. in the Erith mud, 15,760–4. The organic matter in the mud of the River Fitzroy in Queensland, which is totally free from all sewage contamination, contains nearly as much organic matter as the Thames mud, 15,765–70, 15,773–4. A reference to his tables will show that a good deal of rain fell when he took his samples of suspended matter, and therefore the average of 27 · 20 grains per gallon cannot be considered a dry weather average. In order to obtain the average, there must be samples containing a considerably greater and lesser amount of suspended matter than 27 grains. The highest quantity in his tables is 76 grains, and the lowest 10 · 5 grains; but under exceptional circumstances, such as a heavy storm of rain and hail, as much as 100 grains, or even 146 grains, of suspended matter may be found in the water. He considers 76 grains an exceptionally high sample, but it is the average for 12 hours. Had he taken a sample every hour for 24 hours on that occasion, the result probably would have been higher, 15,836–45.

## Mr. AUGUST DUPRÉ, Ph.D., F.R.S.

Lecturer on Chemistry at the Westminster Hospital.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—In 1857 or 1858, in conjunction with Dr. Odling, he was engaged in making analyses of samples of water taken principally at Greenwich, and also at Lambeth and higher up the river. The analyses are not of a character to be compared with the present analyses, but they gave certain indications of the condition of the water, and they brought out Mr. Baldwin Latham's mixing action very clearly. They showed that as the tide flows up, the salt water goes up the centre of the river, and when running down the salt water goes down the sides, and the fresh water down the middle. No comparison can be made between the two analyses as to the purity of the river, as it is infinitely better now above Greenwich, 15,970. The average amount of suspended matter at Greenwich in 1857 and in 1882 between June and September is as follows:—

| Year. | High Water. | Low Water. |
|---|---|---|
| | Grains per gallon. | Grains per gallon. |
| 1857 - | 2·43 | 4·57 |
| 1882 - | 4·05 | 3·93 |

The mean in the two years is very nearly the same, 15,976, 15,986–7.

## Mr. AUGUST DUPRÉ—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

At Greenwich the volatile matter, which indicates organic origin, in 1857 at high and low-water respectively was 35·39 per cent., and 26·45 per cent. when the sewage was discharged above, while in 1882, when the sewage is discharged at Barking, the volatile matter amounts to 24·9 per cent at high-water and 20·20 per cent. at low-water, showing that the suspended matter of the river contains a smaller percentage of organic matter now than it did 25 years ago. By volatile matter he means that which would pass off by ignition as distinguished from mineral matter, 15,977–85. At Woolwich the volatile matter is less at high-water than at low-water at the present time, 15,987–90. There are three methods now usually adopted by chemists for estimating the relative quantity of organic impurity in water. None give the absolute quantity, but general conclusions can be drawn. The permanganate process is the oldest, and although Dr. Tidy stated it was not applicable to the Thames where there was sea water, and had therefore abandoned it, he considers that, if it is properly worked, using a close instead of an open vessel, it gives equally good results in salt water as it does in fresh water, and he has adopted this process all through the river. The principle consists in estimating the amount of oxygen which the water takes from the permanganate, 15,991–2, 16,139–54. The second method is known as the albuminoid ammonia or Wanklyn's process, which estimates the amount of ammonia evolved when boiled with an alkaline solution of permanganate. From this process only comparative, but yet good, results can be obtained, 15,993–4, 16,139–54. The third method is that of Professors Frankland and Armstrong to estimate the organic carbon and the organic nitrogen; but this only gives relative results, and in the case of the Thames it is not applicable, because sea water gives very much organic carbon and organic nitrogen, so that the organic matter in sea water is fouler than in sewage if this process is taken as a guide, whereas the two other processes show the sea water to be pure, and they are the more reliable processes, 15,995–8, 16,139–54. London sewage in 1882 contains on an average, from analysis, 12 grains of chlorine per gallon; it yields 0·44 of albuminoid ammonia; it absorbs 2·80 grains of oxygen from permanganate, and holds about 25 grains of matter in suspension. The suspended matter contains 64·50 per cent. of volatile matter, and 35·50 per cent. of mineral matter. The volatile matter contains 5·75 per cent. of nitrogen, 15,999–16,001. The amount of solid matter per head that goes into the sewers is, fæces one ounce and urine 1·68 ounces, that is, when dried at 212 degrees. Of this 1·68 ounces, roughly speaking, half is urea, which is all converted into carbonate of ammonia before it reaches the river. Of the remainder, one-fifteenth is organic matter, and the rest is mineral, chiefly chloride of sodium. Some of the samples were taken from the outfall sewers as they flowed into the reservoirs, but these contained no urea, 16,002–6, 16,179–96, 16,223–6. From the one ounce of fæces ·14 of an ounce is mineral matter, so the total amount of organic matter per head of population which actually goes to pollute the river is only ·916 of an ounce, which, taking the population at 4,000,000, gives about 100 tons a day, or 36,500 tons a year, instead of "400 tons of filth," as estimated by Dr. Tidy. The amount of oxygen necessary to oxidise this amount would not be more than 200 tons, 16,007–8, 16,179–96, 16,223–6. There is generally more or less turbidity in the river all the way from Teddington to Southend. The amount of suspended matter varies very much, even in the same place, and it is sometimes worse at Teddington than it is at Crossness, even as regards nitrogen. In sewage the suspended matter is 25 grains to the gallon, and in ordinary water the average varies from one to ten or twelve grains, 16,009–22, 16,024. The samples he took in July 1882 and January 1883 show upon the whole that the suspended matter contained less volatile matter than in the earlier years. He hands in a bound copy of his analyses, *see* Appendix B.Z., 16,023–4. He hands in a table giving the amount of suspended matter and the percentage of volatile matter in the suspended matter in the water at Teddington, Kew Bridge, Westminster and London Bridges, Greenwich, Crossness, Erith, Greenhithe, Gravesend, and Yantlet Creek, in 1878 and 1882. The samples were taken in mid-stream at each place every hour during one day, on the surface, half depth, and

Mr. AUGUST DUPRÉ—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

bottom. Each result is therefore the mean of 37 estimations. He also hands in a table giving the mean results obtained between July 1882 and January 1883 at various places in the river between Teddington and Southend, 16,009–24, 16,197–202. He also hands in Table B., which gives the amount of suspended matter in Thames water, 16,024–6. The book of tables he handed in show the basis upon which the deductions are drawn; the details occupy the pages from 1 to 102, and the mean results from page 103 onwards, 16,027–8. The first table deals with oxygen absorbed from permanganate. Table 2 B. and Diagram 2 B. give the same results. At Teddington the river contains a small proportion of impurity, and rises gradually to more than twice the quantity at Greenwich, and then falls to less than the original quantity when Southend is reached. By the time Coalhaven or Northfleet is reached, the river has done its work, and has destroyed the putrescible constituents of the sewage, and the water is restored to an equal condition of purity to what it had when it entered the tidal section of the river. In the neighbourhood of the bridges there is a curious increase of pollution. On the average the river at Blackwall is not more impure than elsewhere except at high and low-water, when the increase of impurity is most marked in the neighbourhood of the outfalls. Diagram 2 B. and Table 2 B. give the mean results for July, August, and September, 1882, 16,029–35. Table 2 C. gives the mean results for high and low-water in January, March, and May, 1882. In the upper part of the river the condition is about the same at high and low-water, while in the lower reaches it is worse at low-water than at high. In July, August, and September, 1882, the river is worse at high-water in the upper part, and better at low-water in the lower reaches, 16,036–40. Diagram 2 F. shows that, if anything, the river is a little purer in 1883 than in 1882, provided the amount of fresh water is the same at each period. But the river is so frequently flushed out that it does not get progressively more foul, 16,041–2, 16,212–17. The next series of diagrams, beginning at page 108, deals with the albuminoid ammonia. Diagram 3 F. shows the results of the analyses in 1878, 1882, and 1883, and the year 1883 is the best throughout. The river is worst at Deptford Creek at high-water, and at Greenhithe at low-water, 16,043–59, 16,203. The last series of diagrams, beginning with No. 4 B., deal with the amount of free oxygen remaining dissolved in the water. If the amount of pollution is very minute, the absorption of the oxygen from the air would prevent any reduction in the amount of free oxygen; but if the polluting matter be introduced into the river more rapidly than the air will supply oxygen, the free oxygen in the water will then diminish, that diminution being the measure of the amount of oxidation of putrescible matter which has gone on, 16,060–3. He has assumed the percentage of free oxygen in the water at Teddington to be 100, and in the diagrams, according to that scale, he has indicated the percentage of the full quantity of free oxygen which was still left in the water which he finds at different places, 16,064–5, 16,173–8. He does not agree with Dr. Tidy's view that the fact of the oxygen having fallen below the standard amount is an indication that the river has lost its power of oxidation. It is an entirely erroneous statement. (*See* Questions 9957–63.) [*Dr. Tidy intimated at this point that he never suggested anything of the kind.*] 16,066–9. Diagram No. 4 B. shows the analysis of the water, made on the spot, between Teddington and Southend. The samples were taken on one day in August and one day in September. Those taken on a day in November were for the purpose of comparison, and it shows that when the weather is cool less oxidation goes on in the water, corresponding to the fact that more organic matter was found in the water during the cooler than during the warmer months. The long curve on the diagram is made up from the samples on the two days only, and it will be seen on reference to Table 4 A., page 66, that the degree of aëration found at Westminster Bridge on the two dates differs but slightly, viz., 54·5 per cent. on August 9th at nearly high water, as against 48·6 per cent. on September 2nd at three-quarters flood, 16,069–72. Starting at Teddington with water thoroughly aërated, it diminishes until at the outfalls there is only 20 per cent. of the original oxygen, and then it rises again at Southend to 96 per cent. of

Mr. AUGUST DUPRÉ—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

oxygen. This is not due to abstraction of oxygen, but that salt water dissolves less oxygen than fresh water. The water is thoroughly aërated, but it is only 96 per cent. of what it would be in fresh water, owing to the proportion of salt water mixed with the fresh. The inference he draws from this is that the sewage from London has been disposed of before it reaches the lower part of the river. Mr. Dibdin's analyses do not go so far down the river as his. They do not extend below Purfleet. The water at Southend is undrinkable, being sea-water, 16,073–6, 16,173–8. At Erith the proportion of free oxygen at low water is at its minimum, or about 8 to 10 per cent. At high water it reaches the maximum, or upwards of 40 per cent. The eddies on the south shore cause the irregularities shown on the diagram. The comparison of the oxygen in the water at Erith at high and low water shows that the river here is beginning to overpower the polluting influence. As each gallon of water contains half a cubic inch of oxygen, he calculates that as much as 233 tons of oxygen pass up the river in one tide, or 466 tons in a day, which is in addition to the quantity in the water as it went down, and is more than enough to deal with the 100 tons of sewage. It is the absolute quantity (not the excess between 8 and 40 per cent.), and is based upon the mean quantity of 25 per cent., not upon the maximum observed, 16,077–93. Mr. Law has gone fully into the question of the chlorine, but he thinks the amount on the 14th September was exceptionally high. He has never obtained so high a result, 16,094. Taking the results of all these analyses, he thinks the river is quite capable of disposing of the sewage that is discharged into it, and that upon the average it is daily got rid of, otherwise there would be a progressive increase in the pollution, which he has not observed, but, on the contrary, the river is in a better condition now than it was five years ago, 16,095, 16,099, 16,212–17. The amount of pollution at Erith, for example, as indicated by his analyses, if added to the Teddington water, would represent 3 to 4 per cent. of pure sewage at low water, and at high water it would be less than one per cent., 16,096–8. The sewage is not all of it oxidised, a great part of it is disposed of by animal and vegetable life before it reaches Southend. The amount of infusorial life in the river in summer is something enormous, 16,100–2. Dr. Frankland stated that the river was getting worse progressively above the outfalls, but this is not the case, 16,103, 16,126, 16,127. During the months of July, August, and September, 1882, he was 17 days on the river. He noticed no offensive or disagreeable smell from the water, except when in the immediate neighbourhood of the outfalls; nor did he notice any in the spray thrown up by the screw of the steamer, which he followed for the purpose. When shaken up in a bottle, there was a faint peculiar musty odour like wet straw which is noticeable all the way down from Teddington, 16,104–7, 16,218–20. Some samples of the water were taken by Mr. Dibdin shortly after the "Princess Alice" accident, but he personally took no samples until November. He has frequently examined the water at that spot, but has never found it offensive. He was there several times during the hottest part of the summer, 16,107, 16,108. The actual stream of the sewage in hot weather is very offensive and very nauseating, but it is not a very powerful or penetrating smell, so that it is very soon lost. In ordinary weather the smell is lost in the actual sewage stream in about 1,000 yards, and it is lost in the river when in a boat within a few hundred yards. On the 16th June 1883 he was in the stream, and he never saw it so well defined before. It was visible 2,000 yards down the river because of the floating matter, not the sewage. The smell given off is carburetted hydrogen chiefly, but there are also some compound ammonias. It is a very complex mixture, but there was no smell 2,000 yards away. He has never before seen the line of demarcation between the sewage and the river beyond 500 or 600 yards, because the stream from Barking Creek comes into the river 200 yards below the outfall, and pushes the sewage into the centre of the river, 16,109–16, 16,227. The result of his analyses confirms his view that the sewage mixes very rapidly with the water of the river, and Dr. Tidy's Table No. 6 shows this very strongly indeed, 16,117–18. There are a great many smells from the factories on the banks of the river which are very penetrating and very

Mr. AUGUST DUPRÉ—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

offensive; sometimes they are so powerful as to be offensive 2,000 or 3,000 yards away. There is in addition a great deal of slaughter-house refuse and manure, and various offensive matters, such as rotten fish for making manure, which are carried on the river in barges, and the smell from these is sometimes really indescribably offensive, 16,119–21. He believes that Wanklyn's process when properly performed is fairly reliable, and that it and the oxygen process give as a rule analogous results. He would not like to say which was the more reliable method. 16,139–41. The analyses as shown in his tables by the oxygen test and the albuminoid ammonia test, broadly speaking, show the same results when the waters are pretty nearly equal, though sometimes different results are obtained when the water is tested by the two processes. Neither of the two processes profess to give the absolute amount of organic matter, they must be compared with themselves and not one with the other, otherwise there will be discordant results. If the oxygen process is compared right through to the end, and the albuminoid ammonia process compared also to the end, the conclusions will be found to be identical, 16,142–54. The diagrams he handed in are based in a general way upon a number of samples, varying from 20 to 3, and in a few cases only one sample. The table is a catalogue of every sample taken, and shows by the mean of the calculations how many samples were taken, and they are all arranged topographically, 16,154–63. Diagram 4 C. shows the percentage of free oxygen dissolved in the water off Erith Pier on the 31st August and 1st September 1882, and he thinks it is a very fair specimen. The days were not selected for any particular purpose, and he did not know that the tides would be exceptionally high. He was at leisure on those days, and accordingly went down the river. There is no doubt also that the river had been scoured out by the heavy rain, and with a high tide the amount of oxygen at high water is greater. The other days on which he took samples were rather unfavourable for the purpose of getting good results. He does not think the amount of albuminoid ammonia varied very much according to Mr. Dibdin's diagram, 16,164–72. Sea-water does not dissolve so much oxygen as fresh water. There is a difference of four per cent. between the two. The amount of oxygen in water varies greatly with the water, and no conclusion can be drawn unless the temperature of the water is given. This unfortunately has not been given by the other side, whereas in his tables it is always given, 16,173–8. He took Professor Law as his authority for stating that the amount of solid matter in the fæces was one ounce, and he thinks it is a very fair estimate. In Mr. Symon's book on Animal Chemistry the quantity of salts, according to Berzelius, varies largely, being as much as 15 or 20 per cent. in some cases, 16,179–88. As regards the amount of solids in urine, he took the figures 1·68 per cent. from Woolf and Lehmann. Liebig, who is an acknowledged authority on these matters, gives the total amount of "dust-dry" residue of the liquid and solid excrement of 1,000,000 people as 45,000,000 lbs. per year, which is somewhat less than two ounces per day. He takes it at 2·6 ounces, which is materially higher, 16,189–96. The water into which the sewage is discharged goes down with the ebb tide about 12 miles. The sewage can be detected to a very small extent at Purfleet by analysing the water, but it must be done very carefully. It cannot be detected by the smell. The presence of the sewage in the water would be shown by analysis to contain a little more albuminoid ammonia, and that it absorbed more oxygen from the permanganate than it would otherwise, so that the volatile matter would not have been destroyed entirely by the action of the oxygen in the water, 16,204–11, 16,227. From chemical experiment, and from ordinary observation extending over a number of years, he founds his statement that the river is not increasing in its pollution. He does not think that 1882 was an exceptionally cold and wet year. The Astronomer Royal's tables show that the temperature was nearly equal to the average, and that the rainfall was very little above the average, 16,212–17. He can distinguish between the sewage and factory smells when he is close to or actually in the sewage stream, 16,218–20. His samples, from which he draws the annual mean, were taken at random, and not on any particular day or in any particular month, so the

Mr. AUGUST DUPRÉ—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

results are not likely to be affected by any exceptional circumstances applying to a particular day, 16,221–2. The salt in the sewage is dissolved in the water, but it would be a very minute fraction compared to the salt which came in from the sea, 16,225–6. He believes that, if a person were blindfolded and taken down the river, he would be able to point out every foul factory to the windward, and every foul boat he passed, by his nose; but he would not know when he passed the outfalls, 16,227.

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls.—He has known the Thames for about 28 years, and for upwards of 20 years has had opportunities of observing the banks when shooting at Canvey Island, and, owing to the quantity and stickiness of mud, it was necessary to have boots extending up to the thigh. The mud was of a brown colour at the top and black underneath, 15,967–9. He has examined and analysed the mud from Teddington to Erith, and finds that it is very much the same all the way down. If there is a difference, the mud in the upper part of the river is slightly fouler than that in the lower portion of the river. For example, the worst mud bank in the river is at Westminster Bridge, on the Middlesex side, 16,122–5, 16,128–31, 16,229. He has never heard any complaints about it from the hospital, 16,132. He hands in Table C. which gives the results of an analysis of some samples of mud collected at Erith only. This shows that the Erith mud bank is practically of an identical composition with the mud banks up and down the river, which he analysed upon the occasion of the Mud Inquiry, and the results are given at page 1,065 in the evidence taken before that Commission. The greater number of the worst banks are to be found in the upper part of the river, 16,133–8.

## Sir FREDERICK ABEL, C.B., F.R.S.

Chemist to the War Department.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—The term "putrefaction" is what chemists call a "metamorphosis," a change in the arrangement of the components of a chemical compound of animal origin containing nitrogen, resulting in the production of a class of comparatively simple bodies some of which have very powerful odours indeed, and those produce what are known as putrifying smells or odours. Those bodies are transient in their character, and are eventually converted into the most simple products, which are, generally speaking, gaseous, and escape into the air in the ordinary course. "Burning up by oxygen" is a transformation which takes place under conditions of temperature and other conditions favourable to that change. There is no addition to the substance, 16,229–30. The analytical results in the form of tables, which were handed in by Dr. Dupré, are the joint work of that gentleman and himself. In a general way he agrees with the conclusions which have been drawn from them by Dr. Dupré, and he agrees with the views expressed by him as to the value of these methods. They give results indicative of the relative degree of purity of a sample of water when examined by a particular method, but there is no single method that gives more than that. By taking the methods together and considering the results which each individually furnishes, a trustworthy indication is obtained as to the quality of the water by chemical examination, but nothing more. Wanklyn's process furnishes a very useful result, and, in combination with the other method he used in connexion with it, results have been furnished upon which the greatest reliance can be placed, and they are the two best known to science, 16,235–9. He agrees with Dr. Dupré as to the purification of the Thames water by the dissolved oxygen contained in it, and he thinks the evidence with regard to the purifying action of oxygen is indisputable and complete, 16,240–3. There is no difficulty in detecting living organisms in abundance in the fresh suspended matter in river water by means of the microscope, but Dr. Sorby will give evidence on this point. The action of these organisms would no doubt be a purifying one upon water contaminated by dissolved organic matter by which they are nourished, 16,253–5. In order to obtain conclusive

SIR FREDERICK ABEL—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

evidence as to whether the Wanklyn process would be trustworthy when applied to samples of water which have been properly preserved in perfectly full bottles for several days after collection, he made a series of experiments. Some of the samples he took were kept for 14 days, and, so far as the proportions of free ammonia and albuminoid ammonia were concerned, they remained unchanged. Some of the samples were examined immediately, or within 24 hours, by the albuminoid ammonia process, part being filtered through an asbestos filter to deprive it of all impurity, and put aside for 14 days; the remainder being put aside also for the same time. In both cases the bottles were only three parts full. It was found that, allowing for a little loss of free ammonia in the filtering, there was but little diminution of free ammonia, and no important alteration in the albuminoid ammonia in the filtered sample; while in the unfiltered sample, in the bottles partly full, the free ammonia, in one instance had almost entirely, and in two instances had entirely, disappeared. This suspended matter, quite apart from the mineral matter, he considers has a purifying action upon the organic impurities, 16,256–9, 16,315–33, 16,365. He has inspected the river in 1878, 1880, 1881, and 1882, but especially in the summer of 1882. Except when he was in the sewage flow, he has on one occasion only been able to recognize at a distance from the sewage the distinct unmistakeable odour of the sewage, and then there was a strong and steady wind blowing from the outfalls. He was near Jenningtree Point about 1,000 or 1,200 yards from the outfalls shortly after high tide. In the flow it can be noticed from about 400 or 500 yards from the outfalls, but, when 50 to 100 yards from the flow, the smell becomes comparatively feeble, and you only get an occasional whiff, 16,260–9, 16,308–15. Before the time of the outfalls, the river between Woolwich and Westminster was frequently in a very offensive condition, and the odour, which he has seldom met with in late years in the neighbourhood of the outfalls, was a matter of by no means unfrequent occurrence between Westminster and Woolwich, 16,270. His house is in Woolwich Arsenal about 250 yards from the river, and his laboratory is about 180 yards distant from the river. During the 28 years he has lived there he has never experienced the least annoyance or inconvenience from the river, 16,271–4. The residents in the Arsenal suffer considerable annoyance from the smells which come from the large and increasing number of factories situated about the outfalls and up the river as far as the Victoria Docks. There are 14 manure works, some of them of the most offensive description, and there are 10 or 12 chemical works. In addition there are the Beckton Gas Works, from which they get smells occasionally. The smells are noticeable on Woolwich Common, and extend as far as Blackheath, 16,276. In 1866 he was directed by the War Office to enquire into the complaints that were made at that time of emanations from the factories that were growing up near the outfalls, and he found there was substantial cause for complaint in consequence of the careless manner in which those noxious trades were carried out. He was a member of the Noxious Vapours Commission which sat in 1877, and the whole of the evidence was very conclusive as to the very considerable extent the neighbourhood suffered from the emanations of the noxious vapours from those factories. No allusion was made to the outfalls contributing in the smallest degree to these nuisances, 16,277–83, 16,285–90. He has carefully examined the analytical results of the experiments made on both sides recently, and fails to see any evidence of an increasing pollution of the river. On the contrary, he feels confident that it has been well established that the river is competent to deal with the amount of impurity discharged into it, and that the purifying power at the present time is in excess of the polluting influences, 16,284. 16,291–300. The river, he believes, is capable of dealing with a very much greater degree of pollution than it does now. Within a particular and very limited area at certain times the river might become offensive in consequence of the presence of the sewage, but he has never found it to be so even in the hottest weather, 16,291–300. He believes that odours from the fish-manure works have been not unnaturally ascribed to the sewage, because the odour is something like, though much more intolerable than the emanations from excreta. He is convinced that in many instances, and certainly at Woolwich, smells of this description have been mistaken for smells emanating from the sewage outfalls. An "educated" nose can distinguish between the factory and sewage smells, but the "popular" nose would not be able to do so, 16,301–7. As regards the unfiltered sample of water, it contained both matter in suspension and matter in solution, and the disappearance of the free ammonia may have been due to animal *or* to vegetable organisms existing alive in the suspended matter. If the ammonia had been oxidised by the oxygen, it would have been equally oxidised in the filtered sample. He would not pretend to say that the organisms are diatoms and bacteria, but they probably are, 16316–33.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—He received samples of mud taken from the river which were placed in the laboratory, where they became putrescent and emitted an unpleasant smell. This smell is characteristic of any mud which contains vegetable matter, or animal matter, but the latter is comparatively rare in muds, 16,231–4. There is no quantitative method for determining the actual amount of organic matter in muds, 16,237. There are some mineral matters in suspension in a polluted river which act upon certain classes of dissolved organic matter as precipitants, throwing them down in the form of insoluble materials, and, indeed, fixing them so that they undergo very gradual change afterwards and may be considered to be rendered practically permanent by this precipitation. There are also mineral matters which have the effect of fixing any sulphur compounds which are developed by the putrefactive decomposition of animal or vegetable matter containing sulphur, such as, for example, clays containing oxide or carbonate of iron. If by the putrefactive decomposition of the nitrogenous organic matter in suspension sulphuretted hydrogen be evolved, those iron compounds will fix the sulphur in the sulphuretted hydrogen, and will act equally upon some other sulphur compounds, producing sulphide of iron, which gives that black appearance to the mud, conveying to the uneducated mind a notion of filth and impurity which is erroneous, inasmuch as it is really due to a purifying action; and this would account for the black appearance of the mud deposits at Erith. The black mud becomes brown in appearance if it is exposed to the air, consequent upon the decomposition of the iron sulphide in the mud by the action of the air. Sulphide of lead would be black as well as sulphide of iron. The black sulphide has no smell, 16,244–50, 16,334–53. He has been unable to detect any smell in the mud at Erith, nor was there any smell coming from the gas bubbles in the mud, though he tested them, and the mud itself, for sulphuretted hydrogen. The gas he found consisted chiefly of marsh gas, 16,251–2, 16,354–7. The iron which turns the mud black comes from the mineral suspended matters which are continually washed about in the river and deposited on the saltings. The saltings do not turn black, because they have not the opportunity of being subjected to the process of being mixed up in a finely divided state with the sewage in the water, and thereby undergoing change as the sewage mud does, 16,334–341. Iron comes from the road detritus left by wheels and horse-shoes. The blackness of the mud at Erith is certainly not produced by the dark or black colour of the sewage, 16,342–51. No line can be drawn at which it can be said that a matter simply putrefies and does not oxidise, the oxidation proceeds concurrently with putrefaction. There are some animal substances which are more liable to putrefy than others, and some which would more readily oxidise if they were exposed to conditions favourable to oxidation. Given putrescible animal matter in mud, and expose it to the necessary temperature, such as a summer heat, it must of necessity putrefy, but oxidation will be going on at the same time, 16,361–4.

EFFECT UPON HEALTH IN THE NEIGHBOURHOOD OF THE MAIN OUTFALLS.—There are a number of official residents in Woolwich Arsenal, and although during the last 28 years there have been the usual visitations of sickness of one kind or another, there has not been a single case of sickness which could be ascribed even remotely to the outfalls, 16,275.

INJURY TO FISH.—The suffocation or poisoning of fish, as low down as Gravesend, he attributes to the effect of the sewage, which absorbs the oxygen in the river, so that there is not sufficient left to support the life of fish, 16,358–60.

## Dr. AUGUSTUS VOELCKER, F.R.S.,

Consulting Chemist to the Royal Agricultural Society of England.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He was with Mr. Dibdin on the 16th June 1883 when they saw an abominable nuisance arising from the slaughter-house refuse scattered all about the foreshore at Erith. He also counted no less than 14 sewers or sewage pipes that discharged their contents on the foreshore. This was quite enough to account for the complaints of nuisance from people who work in the mud and along the foreshore, and on this occasion it was so bad that Sir Frederick Bramwell who accompanied him, declined to proceed farther, and turned back, 16,366–9, 16,428–33. In the months of June, July, and August, 1882, he made several inspections of the river with Mr. Dibdin and Dr. Dupré, between Westminster and Purfleet. He found no bad smells arising from the river, except in the direct sewage stream when the smell was bad, but it gradually disappears, and at a distance of 600 or 700 yards, according to the state of the wind, it entirely disappears. Even when the water is shaken up there is only that faint smell which is perceptible all along the river from Westminster to Erith, 16,370–3, 16,422–7. The factories discharge a very large quantity of a most penetrating, disagreeable smelling vapour. At the London Manure Company's Works at Cubitt Town, from 40,000 to 50,000 tons of artificial manure are manufactured annually, and the smell produced upon the addition of sulphuric acid to some of the refuse material, such as blood or fish, is most obnoxious. It is not due to any ammoniacal emanations, but to the propionic, phocenic, and similar volatile fatty acids. The odours travel a long distance, and are perceptible three-quarters of a mile off up and down the river when the wind blows in the proper direction. Whenever he went down the river he did not smell the water, but he always smelt the factories, 16,374–5. In considering the comparative degree of purity of the Thames, he has taken account of the character of the suspended matter, whether it was more of a mineral nature, or of a combustible nature, the amount of oxygen consumed, and the amount of albumenoid ammonia found. The general conclusion he has arrived at is that which has been already stated by Dr. Dupré. In the most polluted Thames water he has invariably found nitrates present, not in the reservoirs, but within 1,000 yards of the outfalls, or in any part of the river where there is an abundant supply of oxygen. This shows that there is always plenty of oxygen to destroy the most obnoxious or most putrescible part of the organic matter. It cannot be denied that the discharge of so large a body of sewage from an outfall must create a local nuisance, say for 1,000 yards from the outwards, if so much; but it is remarkable how quickly this peculiar sewage smell is destroyed, and he is certain that people who are not intimately acquainted with the various smells, mistake certain animal emanations, such as those which come from the fish manure works, especially in a dilute condition, for sewage, 16,376–80, 16,411, 16,422–7. He agrees with Dr. Dupré and Sir Frederick Abel, that the dissolved oxygen to be found in the Thames water is more than sufficient to oxidise the polluted matter which is poured into it, and he also thinks that for giving comparative results, Wanklyn's method is the right one to employ, 16,381–2. He enumerates the various factories, on the banks of the river where artificial manure is manufactured very extensively, the smell from which is very offensive and remains so for a considerable distance. From the soap and oil works there is always a prevalent oily smell. The manure works smell most in the spring when there is a considerable pressure of business, 16,382–8, 16,397. From the ammonia and tar works there is always a strong smell, and when sulphate of ammonia is made sulphuretted hydrogen is given off, which is most unpleasant. On the 16th June last the smell of sulphuretted hydrogen from the Beckton Gasworks was very powerful. They are the most extensive sulphate of ammonia works in the kingdom, and manufacture about 30,000 tons a year. If great care were taken either to absorb or burn off the sulphuretted hydrogen, there would be no smell given off, 16,389–94. There is a good deal of gas lime produced at the gasworks also, which is an unsaleable commodity in that locality. Even the ordinary refuse lime from the Silvertown Soap Works has to be carried out to sea. Gas lime smells of sulphuretted hydrogen and gas and tarry matters, and the gas lime when exposed to the air gives off the sulphuretted hydrogen which creates a nuisance on the river as it is carried away in barges, 16,395–6, 16,414–17. From the fish manure factories most offensive odours arise, which travel a long distance, and produce the greatest nuisance. It is very persistent in its character, and is not easily oxidised. Upon several occasions he has smelt the fish factories at Erith. The two greatest offenders in this way are Mr. Johnson and Mr. Lang, 16,397–9, 16,418–21. Most of the factories he has mentioned are situated between Woolwich and Crossness, and others are close to Crossness. He is able to discern the difference between those smells and the sewage smells, 16,400–2. He is not prepared to say whether the sewage is at all purified on its way through the sewers, or in the reservoirs before it is discharged into the river. For agricultural purposes it would be just as good 40 miles from town as it would be five miles from town. It gets purified and may become almost innocuous, so as not to create any nuisance upon being applied to the land. Inodorous and clarified sewage is the better for irrigating purposes, and it would be better still if it could be filtered, because the suspended matter forms a crust upon the surface which is injurious to the vigorous growth of plants, which closes up the pores of the earth, 16,403–10, 16,412. The summer of last year was cold when he was inspecting the river, 16,426–7. When at Erith he noticed no sewage smell, and although he saw some sewage mud on the shore (at low tide) it did not smell, 16,430–33. He does not know the distance at which sewage farms as a rule are established from a town, though at Bedford the farm is close to the town, and is conducted without any nuisance to the inhabitants. There are paths running through the farm which are much frequented by people, 16,434–7.

## Professor WILLIAM ODLING, M.B, F.R.C.P., F.R.S.

Professor of Chemistry in the University of Oxford.

Scientific Evidence as to the foul State of the Water in the River near the Main Outfalls.—He has been acquainted with the Thames for 25 years, and has been very largely engaged in investigations as to its character during the years 1857, 1858, 1868, 1869, 1882 and 1883. He entirely concurs in the evidence of Dr. Dupré, and Sir F. Abel, 16,438–41. The self-purifying power of the river is in excess of the polluting action of the sewage discharged into it, so that even the worst stretch of water oscillating above and below the outfalls does not get so polluted as to be a nuisance. That fact has been established by ordinary observation of the river, because as a body of water it neither smells nor looks offensive, and there is no evidence to the senses that it is polluted. The analyses show that there is no definite body of polluted water which can be distinguished from the general mass of water, but that starting from Teddington, there is a gradual increase of pollution until you get to the outfalls, and then a gradual decrease of pollution till you get to Southend, when the water *qua* organic matter is in exactly the same position as it was at Teddington. The increase and decrease is perfectly continuous, and forms a curve, if the average of a number of observations be taken, 16,442–3. Taking the average of the three hot months in 1882 the water at Erith is such as might result from adding one part of average sewage to 27 parts of Teddington water, and at Purfleet it would be equal to 1 to 49 parts, 16,443. The reason he did not adopt the combustion process to ascertain the condition of the river was that the coarser method, that is Wanklyn's process, and the permanganate process, was better adapted for the purpose, 16,444–5, 16,549–53. He calls attention to Dr. Frankland's results, which show an excess of organic carbon at St. Paul's pier as compared with that at Erith, and that, at the time the samples of water were taken, there was no appreciable sewage in the water at St. Paul's. It follows, therefore, that there must have been a minus quanty of sewage at Erith. He thinks that the amount of organic carbon stated by Dr. Frankland to be at St. Paul's Pier, viz :—·503 parts in 100,000 parts does indicate the presence of sewage, although Dr. Frankland said it did not, 16,445–53. At no time does the pollution of the worst stretch of water become excessive; it is partly due to dilution, and partly to the destruction or oxidation of the sewage matter. Taking the normal proportion of oxygen in the water to be 1·84 cubic inches instead of 2 cubic inches, there are

PROFESSOR WILLIAM ODLING—*continued.*

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

several hundred tons of oxygen in the water over and above the quantity required to oxidise the sewage. According to his experiments the proportion of oxygen in the flood water at Erith is reduced to above one-fourth of its normal amount, three-fourths being expended in oxidising the sewage. This series of experiments was put in by Dr. Dupré in his evidence, 16,454–7. 16,572. The amount of oxygen in salt water is somewhat less than that in fresh water, but for the purpose of this inquiry it is practically the same. Taking the quantity of flood water passing Erith upon a single tide to be 3,200,000,000, cubic feet, that water actually contains 200 tons of oxygen which it has to expend; and having already expended 600 tons of oxyon it must have oxided several hundred tons of organic matter; 200 tons of oxygen sent up on the flood tide would suffice, at any rate, to oxidise over 100 tons of organic matter; and, as the quantity of organic matter discharged into the river at one tide does not exceed 50 tons, there is always more oxygen in the water than is required to oxidise the sewage, and that would account, in his opinion, for the sewage not creating a nuisance. There is enough oxygen left in the water to do the work over again, and, as the effect of that, the oxygen sometimes has been reduced to one-tenth of its normal quantity, 16,458-66, 16,555–71. He has no reason to suppose that sea water does not part with its oxygen as readily as fresh water for oxidising purposes, 16,467–70. There is no evidence to show how long the oxygen which has disappeared has taken in disappearing. The only facts known are that the fresh water coming down and the sea water coming up, each contain about two cubic inches of oxygen per gallon, and that the intermediate stretch of water contains only one-fourth of that quantity, and it shows that the organic matter is being destroyed faster than the water can fully saturate itself with oxygen. It has never yet happened that the amount of organic matter poured into the river has been so great that the water coming up has been inefficient to do its work, 16,471–8. He has considered Dr. Tidy's statement that the power of oxidation is diminished, when the amount of oxygen is diminished in the water, in a greater degree than in the proportion of the diminution of the quantity of oxygen. Sir F. Abel and Dr. Dupré are of opinion that it is not so: but he thinks there are some facts in favour of that theory and some facts which are opposed to it. He thinks that, with the reduction of the proportion of the oxygen, the oxidising power might be diminished in a somewhat more rapid ratio, which he attributes to the oxygen being more diluted, 16,479-81, 16,572. When the oxygen in the water is reduced very largely there is a continual tendency on the part of the water to recuperate itself from the air. Vegetation is an additional source of oxidation in the water, 16,482–4, 16,573-85. He wishes to call attention to those experiments of Dr. Frankland's, which are given in detail in the 6th Report of the Rivers Pollution Commission. Of the mixture of river water, and five per cent. of sewage, Dr. Frankland found that in two days 16 per cent. of the sewage matter had been destroyed; but Dr. Frankland put into the bottle from four to six times as much sewage as all the oxygen in the bottle could oxidise; therefore the amount destroyed was equivalent to 64 per cent. of what could be possibly oxidised. Dr. Frankland's experiments on the subject of oxidation seem to be of two kinds. They either prove nothing, or they prove the case for the Metropolitan Board of Works, and the instance he has just quoted belongs to the latter class, 16,485-90. In warm weather the smell given off by the discharge of the sewage stream is sometimes offensive and nauseating, but it does not spread very far. He has not been able to trace any substantial increase of disease to the smell from the river when, before the outfalls were opened, the sewage oscillated between Greenwich and Westminster and had an extreme stink, and the river was more black than brown. The volume of water in those days was not sufficient to oxidise the sewage, 16,491–7, 16,505–7, 16,589. If the sewage is discharged on the flood tide it might reach Woolwich in an offensive condition, but not otherwise. It might get into eddies and be unpleasant, 16.498-504. Since the outfalls have been in existence there has been no smell in the water above London Bridge, 16,505-6. The river does not get so well aërated in hot weather as in cold, 16,525. In 1865, he stated that the discharge of sewage at Barking would not be sufficient to purify the upper

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS—*continued.*

Thames. It has not affected the condition of things at Barking, but it has affected the condition of things in the upper river to which that question applied, 16,525–38. Twenty years ago he traced sea water as high up as Wandsworth, and he has said that where sea water went he believed sewage would go also, 16,539–41. He made one series of analyses by the organic carbon process to check the analyses of the other side, and they came out substantially the same. He took a minor part in Dr. Dupré's experiments in testing the oxygen process in salt water, but that is the only time he has tried it, 16,542–8. He believes that a running river like the Severn, with vegetation in it, and which is aërated by weirs, &c., would be more likely to dispose of sewage than a tidal river like the Thames, 16,588. He does not believe that sewage requires a long flow of river to be disposed of, and if Dr. Frankland said that, he does not agree with him, 16,585–6. He cannot speak definitely on the subject, but he thinks that if sewage is discharged into sea water in sufficient quantity to be putrefactive, it is probable that the nuisance would be greater than in fresh water. Sea water would retard putrefaction, but not oxidation, 16,590–1.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—In a Report he made in 1858, as medical officer of health for Lambeth, he attributed the chief source of the smell in those worst times, to the large deposit of mud banks which existed in the river at that time, and were disturbed by the flow of the tide, causing considerable nuisance. He said then, that at whatever point the sewage was discharged, organic mud would be deposited on the exposed flat banks of the river, unless the scour of the river was increased. Substantially that is his opinion still, for the formation of the Thames Embankment has cleared out the upper part of the river, and the banks of mud at Lambeth are small compared to what they were in 1858, 16,507–20. The temperature of the mud banks, with the sun shining on them, is higher than that of the water, and the higher the temperature the more rapidly putrefactive change goes on. It is possible that under a hot sun the mud might reach the temperature of 120 degrees, but it was a slip either on his part or on that of the printer, if it is stated in the evidence of the Thames Embankment Commission that he gave that temperature as the regular heat of the mud, 16,521–4.

## MR. HENRY CLIFTON SORBY, LL.D., F.R.S.

SCIENTIFIC EVIDENCE AS TO THE FOUL STATE OF THE WATER IN THE RIVER NEAR THE MAIN OUTFALLS.—For 25 years he has devoted a great deal of attention to microscopic inquiries, especially in connexion with the structure of rocks, and loose deposits like mud and sand. Three years ago he began to investigate the mud and deposits which are to be found in the River Thames, and for this purpose he lived on board his yacht for a considerable time each year. He hands in the result of his investigations in the form of a report. (*See Appendix C.B.*), 16,592–7. He never found anything to complain of all the time he was on board his yacht as regards the river, nor did any of his crew. He used the river water for washing the decks, but not for cooking purposes, 16,598–600. There are a vast number of divisions included under the head of algœ, but those to which he has specially referred are the confervoid algœ, the desmid algœ, and the diatoms; and these he has united together in Diagram No. 1, 16,682-6.

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS.—For 25 years he has devoted a great deal of attention to microscopic inquiries, especially in connexion with the structure of rocks and loose deposits like mud and sand. Three years ago he began to investigate the mud and deposits which are to be found in the River Thames, and for this purpose he lived on board his yacht, for a considerable time each year. He hands in the result of his investigations in the form of a report. (*See Appendix C.B.*), 16,592–7. He collected a number of samples of water from Hammersmith to Gravesend, and allowed the suspended matter to deposit. That mud was then investigated by the microscope. Latterly he used an apparatus in the form of a very fine sieve, which retained all the suspended matter, 16,601–5. He

MR. HENRY CLIFTON SORBY—*continued.*

SCIENTIFIC EVIDENCE AS TO THE DEPOSIT AND ACCUMULATION OF FOUL MUD NEAR THE MAIN OUTFALLS—*continued.*

examined also the mud which had been recently deposited upon the surface, and found that it is materially different from the mud an inch or two below. At Erith he found a very large number of desmids and diatoms. These and conferva are well recognised plants which abound in the river, about which there can be no kind of doubt. They live in fresh or brackish water, 16,606–10. The brown colour of the mud is due to the countless thousands of desmids and diatoms. They do not like to be below the surface, and when collected in a glass beaker they can be seen to wriggle up to the top, where they multiply, 16,111–12. They contain a large amount of chlorophyll, and when exposed to the sun light they give off a considerable amount of oxygen. The yellow colouring matter they contain can be dissolved, and then by means of the spectrum-microscope they appear green, 16,613. He does not know whether the microscope has ever been employed in a definite manner to ascertain the quantity of sewage matter which was in the suspended matter of the water or in the mud, but by using that method in the case of the Crossness Bank he arrived at the same conclusion as the arbitrators did at the time of the mud inquiry, 16,614. He examined the matter in suspension to ascertain what were its special characteristics, and found it contained detritus from roads, horse droppings, and human fæces. The horse droppings contain a great number of the characteristic objects which are given by sewage, the most special feature being the hairs of oats. "A unit" of human fæces contains a large portion of undigested muscular tissue which is not in the condition in which it is found in roasted flesh; it has undergone such a process that it cannot be digested successfully by a warm acid solution of pepsine. These fibres also resist the action of dilute caustic potash. He determined the percentages of these substances all the way down the river. 16,615–20. These substances are not to be found in the pure mud of the Essex river, 16,621. The amount of human fæces is greater above Teddington Weir than in any part of the river below. From Teddington Weir the quantity increases to London Bridge, then decreases, and again runs up to another maximum between Barking Creek and Erith, and then decreases to the sea. The quantity of horse droppings increases to a very large maximum at London Bridge, it drops sharply to Blackwall, and then decreases regularly to Sheerness, 16,222–4, 16,716–23, 16,797–8. He was very much struck with the enormous number of excrements of minute crustaceans, mainly entomostraca. At page 13 he has given the number of those excrements which can be counted in a given unit weight of the mud. At Hammersmith it is sometimes as much as 1,100 in one-twentieth part of a grain, and the average number of such excrements in the surface water of the river is 166. At Erith in August, taking into consideration the entire depth of the river, the average number was 360, but in May it was only 240. He found that in summer when there was a large number of these excrements there was a much smaller quantity of the detritus of human fæces, but in winter, when these animals live to a very small extent, the detritus of human fæces existed to a much larger amount. At Greenhithe he collected a number of these entomostraca, and put in some human fæces with them, when they at once attacked it, and he saw them eating it. He believes that the maximum number in the summer would be about 25 per gallon, and that as a grain of human excrement contains parts which they can neither eat nor digest, there would not be more than $\frac{1}{20}$th of a grain per gallon for 25 to feed upon. Small as these little creatures are, he feels sure they play a most important part in the destruction of the sewage, 16,625–29, 16,634–5, 16,681, 16,701–8, 16,726–36, 16,785–8. The anellids and other mud-worms perform the same function in the water as the earth-worms do upon the land. He has collected mud in glass beakers and watched these mud-worms wriggle through it, and he has no doubt that their nutriment is the mud which they swallow and eject, utilizing the organic matter present, 16,630–2. His experiments were made at half-ebb and half-flood, and as a general rule there is much more mud held in suspension near the bottom than near the surface, and there is a different distribution of the constituents, 16,633. He found that on the average the amount of sewage material carried up on the flood-tide was 40 per cent. of that carried down by the ebb-tide, and that at spring-tide only 24 per cent. was carried up of that carried down. He produces samples of materials which would not pass through a strainer with apertures of one two-hundredth part of an inch in diameter. All the normal mud would pass through, 16,636, 16,761–81. By means of the microscope he was able to determine between quartz sand and flint sand in the mud. The sand of the sewage contains about 14 per cent. of flint, but the old sand that was deposited to form the saltings contains only one per cent. of the flint, and that enabled him to determine approximately the amount of sand derivable from sewage, which is now contained in the mud deposited at Erith. He produces samples of sand from the drift, from the sewage, from Coalhouse Point, from the saltings, and from the banks at Erith, 16,637–40. The sand in the mud banks at Erith is exactly the same sand as that which is found in the old saltings in the bed of the river, and differs considerably from the sand in the sewage, 16,641–4. He finds, in conclusion, that the quantitative method he has employed is far more accurate than is requisite for the purpose, as it has enabled him to obtain an idea of the character of the contamination in various parts of the river, a large portion of which are removed, especially in summer, by the action of minute animals, and that the combined effect of these, and of the large volume of water in the river near the main outfalls, is to rapidly reduce the percentage of sewage in the mud and in the water to considerably less than what it is above the outfalls. He produces a diagram illustrating this. He believes that the greater amount of impurity near London Bridge is not due to material drifted up from the outfalls, 16,645–61, 16,717–23. The constituents of the mud, say at Erith, are composed of clay and shale deposits, the material produced by the decomposition of feltspar, organic matter, diatoms, &c. Four per cent. of this is composed of the indestructible part of ordinary sewage which is innocuous, and one per cent. of the destructible, or detritus from human fæces, 16,662–72, 16,680, 16,687–92, 16,789. The smell would be very small. He never smelt the mud at Erith, and the only nuisance he experienced while living there was from the coal dust at Messrs. Beadle Brothers' Coal Wharf. His men all laughed at the smell of the river, but they complained of the smell from the factories. 16,673–79. There are a vast number of divisions included under the head of algœ, but those to which he has specially referred are the confervoid algœ, the desmid algœ, and the diatoms. These he has classed together in his Diagram No. 1, 16,682–6. In estimating the number of fragments in an unit volume of material he has counted all those about which there can be no possible doubt, but those which he cannot completely prove to be derived from muscle, fæces, or any other material, as the case may be, he has only counted half. This gives a fair result, and is similar to the principle adopted in counting the corpuscules of blood, 16,693–700. He explains the method by which he prepared his specimens for the microscope. The accuracy with which the proper quantity is taken up each time for the glasses, and the success of the method depends on the skill of the operator, but from constant practice he is able to do it now in a manner which astonishes him, 16,701–8. Gallon per gallon the river is worse at London Bridge than at Barking, and Diagram No. 5 shows this, 16,717–23. He agrees with Dr. Tidy that spirals are developed from green vegetable food, but a large number are found in the road drift which have come from the excrement of horses, 16,724–5. The entomostraca abound in the sea, in river streams, where there is neither sewage matter nor muscle, and possibly they are to be found in well water, 16,726–36. The increase in the number of algœ at Barking as distinguished from Woolwich is partly due to the fact that they belong to the class which live better in brackish water. They are different to those which are found at London Bridge, and are larger. The carbonic acid in the river water near the outfalls enables them to grow more rapidly than they can do in pure water, 16,737–46. Samples of sewage were taken at Crossness as well as at Barking, but as the latter is a stronger and a richer sewage than at Crossness he has only mentioned Barking in his tables, 16,747–51. Immediately above Teddington Weir the water contains 32 per cent. of oat hairs and 28 per cent.

## Mr. HENRY CLIFTON SORBY—*continued.*

Scientific Evidence as to the Deposit and Accumulation of Foul Mud near the Main Outfalls—*cont.*

of muscle fibres. Immediately below the Weir the muscle fibre falls to 10 per cent. because it is diluted with a larger amount of mineral matter, and there was a larger amount of mud per gallon, because that mud is stirred up by the fall over the river. The mud is worse at Teddington than at Barking Creek, but the water itself is not, 16,752–69. The chemical gentlemen who have given evidence have entirely overlooked the action of the algœ on the mud. They increase most rapidly, and it is stated that one of these Cyclops can, in a year, if they all survive, give rise to 4,000,000,000, if the conditions are favourable and they have abundance of food, 16,787–8. The Cyclops are visible to the naked eye, and are about one-sixteenth of an inch in length; some are larger. At Crossness there are a greater number of Daphnes, which are larger than the Cyclops. The cause of their death is their being drifted into water which is too salt for them, 16,790–6.

## Mr. HUGH HERBERT MASON, M.R.C.S., L.S.A. San. Sc. Cert. Camb.

Medical Officer of Health for East Ham.

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls.—He has held his present appointment since 1877, 16,801 He has not noticed any smell from the sewage in the river at Barking or at East Ham, but he has smelt the sewage as it is discharged from the outfall, and he has noticed the smells from the factories. At high-water he has never noticed any indication of sewage at Barking, 16,833–7. He observed nothing unusual in the appearance of the bodies which were brought ashore after the "Princess Alice" accident, nor was there anything different in the state of their clothes to that of people drowned elsewhere, 16,838–44. He saw about 30 of those who landed alive. They were suffering only from the effects of their immersion, and not from sewage poisoning. He has seen people suffering from zymotic diseases caused by sewer gas, and he has seen cases of poisoning by sulphuretted hydrogen. This produces a comatose condition previous to death or recovery, 16,845–53, 16,890–2, 16,914–15. He has occasionally been able to distinguish the sewage smell from the factories smell, but he has not paid much attention to the subject, as his duties do not often take him near the river, 16,880–2. He has never seen, nor has he ever heard of a case of death from drowning being accelerated by the presence of sewage in the river, 16,883–9, 16,898. Drowning is suffocation, and one symptom is that froth exudes a little at the mouth, 16,893–7. He saw some of the bodies which were not recovered for some time after the accident, but he did not notice that they decomposed more rapidly than other bodies which had been drowned elsewhere in the Thames, or in an

## Mr. HUGH HERBERT MASON—*continued.*

Scientific Evidence as to the Foul State of the Water in the River near the Main Outfalls—*continued.*

ordinary pure river. The existence of sewage would rather manifest itself in those who recovered than in those who were drowned, if there were any deleterious matters given off from the sewage. He saw no cases of retarded recovery, 16,899–905. His district is not entirely a riverine district. A part of Kent intervenes, in which the outfall is situated, 16,906–8.

Effect upon Health in the Neighbourhood of the Main Outfalls.—The district of East Ham includes that portion of the town of North Woolwich which is not in the County of Kent, and it extends back from the river for about three miles, 16,800–4. The health of the whole district is about the average of England, and there is no difference berween the health of the riverside population and the rest of the district. It is not specially subject to zymotic or other diseases which might be attributed to emanations from the river, 16,805–9. His private practice is in a different area to his official district, which is bounded by the eastern side of Barking Creek, 16,810–13. The employés of Lawes' Chemical Works live in about 50 cottages at the mouth of the creek, and as medical attendant to their club he finds their health is about the average. Zymotic diseases have not been prevalent amongst them, and there has been no typhoid fever, or diphtheria. The epidemic of scarlet fever in 1881 did not extend more beyond the riverside district than in other parts, 16,814–27. The population on the banks of Barking Creek is a low class labouring population. They are not more unhealthy than people of a similar class living elsewhere. He has not been able to trace any illnesses there to emanations from the creek, 16,828–32. He lives about a mile and a half from the river, and there are about 9,000 people living in his district. There was an outbreak of scarlet fever in the district in 1875, but he was not officially connected with the district at that time. There was a very high zymotic death rate all over the district and West Ham, which extended also into the country. It was supposed that the fever came down to Barking from London, 16,854–72. In 1879 and 1880 scarlet fever and diarrhœa were prevalent, and the zymotic death rate was high at that time, 16,873–77. Barking contains a good many cesspools, but there is a sewer there. The water supply is from the Grays Works, and nearly all the people obtain their water from that source now, though they did not at the time when there was so much sickness, 16,909–13. The Beckton Gasworks are in his district, and the men are healthy for their class, and considering the way they live, 16,916–7. The houses, in which the men employed at Lawes' Factory inhabit, are situated about 20 yards from the river wall, and the factory is almost on the bank of the river, 300 yards below the outfall. The population of these houses is about 200 including women and children, 16,918–20, 16,826.
